TI Effects of capsaicin on liver microsomal metabolism of the tobacco-specific nitrosamine NNK.

SO Cancer-Lett. 1993 Nov 30. 75(1). P 45-52.

JT CANCER LETTERS.

PT JOURNAL-ARTICLE (ART).

AB Chemically-induced mutagenesis and carcinogenesis is modulated by various plant products, some of which are present in the human diet. 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK), a potent carcinogen in tobacco and tobacco smoke, is activated by microsomal enzymes. In this study, we investigated the effects of capsaicin on the in vitro metabolism of NNK. Capsaicin is the principal component of Capsicum fruits used widely by humans as a food additive. Liver microsomes from saline-injected, phenobarbital-induced and beta-naphthoflavone-induced hamsters were used. Microsomes from phenobarbital and beta-naphthoflavone-induced animals expressed decreased NNK reduction and enhanced pyridine-N-oxidation, but did not significantly alter alpha-carbon hydroxylation of NNK. Capsaicin (0.5 mM) inhibited the formation of all metabolites of NNK by all microsomal fractions and inhibited alpha-hydroxylation by phenobarbital-induced microsomes more than by either of the other two treatments. Our results suggest that capsaicin, as a naturally occurring dietary constituent, possesses *antimutagenic* and anticarcinogenic properties through the inhibition of xenobiotic metabolizing enzymes. Author-abstract.

JT YAO HSUEH HSUEH PAO ACTA PHARMACEUTICA SINICA.

PT JOURNAL-ARTICLE (ART).

AB Ranunculin (RAN) was shown to be an *antimutagenic* agent selectively against mitomycin C (MMC) or methyl methane sulfanate (MMS) treated Salmonella typhimminum TA100/TA102. It decreased the formation of micronucleus of MMC induced polychromatic erythrocytes (PEC) from 46 +/- 9.2% to 20 +/- 6% in mice. The inhibition of RAN on the incorporation of 3H-TdR into DNA disappeared after incubation with rat liver microsomes and cytoplasm since RAN was found to be metabolized by rat liver microsomes in vitro, resulting in a new

absorbance peak at 258 nm, determined by RP-HPLC. The data show that RAN may have both *antimutagen* and antitumor activity, but the latter action may disappear by metabolic transformation. Author-abstract.

TI A simple method to assess in vivo repair of ultraviolet radiation-induced lesions of specific DNA sequences of restriction sites.

SO Radiat-Res. 1993 Dec. 136(3). P 397-403.

JT RADIATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Based on the direct relationship between ultraviolet irradiation of DNA and its susceptibility to restriction endonucleases, we have devised a simple method to quantify in vivo damage and repair of selected restriction sites. The simplicity and power of the method were demonstrated with HindIII restriction endonuclease and pAc360-501-beta-gal plasmid in UV-irradiated Escherichia coli cells. The large number of available restriction endonucleases makes the method quite flexible. This method provides a simple and inexpensive means to screen mutagenic and *antimutagenic* drugs that interact with the DNA repair mechanism. Author-abstract.

SO Mutat-Res. 1994 Jan. 320(1-2). P 9-22.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Bio-anticlastogenic effects of unsaturated fatty acids--cis-4,7,10,13,16,19-docosahexaenoic acid (DHA), cis-7,10,13,16,19-docosapentaenoic acid (DPA), and cis-5,8,11,14,17-eicosapentaenoic acid (EPA)--on chemically induced chromosome aberrations were studied in cultured Chinese hamster cells. The induction of chromosome aberrations by the crosslinking agents mitomycin C (MMC) and cisplatin (DDP), the SN-1 type alkylating agents N-ethyl-N'-nitro-N-nitrosoguanidine (ENNG), methyl nitrosourea (MNU), and ethyl nitrosourea (ENU), and the SN-2 type alkylating agent ethyl methanesulfonate (EMS), but not by the SN-1 type alkylating agent N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) and the SN-2 type alkylating agent methyl methanesulfonate (MMS), was suppressed by post-treatment with DHA, DPA, and EPA. Since there was no opportunity to inactivate mutagens by desmutagenic mechanisms

under the post-treatment schedule used, the results demonstrate the bio-anticlastogenicity of unsaturated fatty acids. Suppression by the unsaturated fatty acids was observed when cells were treated during the G2 phase, suggesting that G2 events were responsible for the bio-anticlastogenic effects. Two saturated fatty acids with the same number of carbons as the studied unsaturated fatty acids--docosanoic acid and eicosanoic acid--did not affect chromosome aberration induction, suggesting the necessity of unsaturation for fatty acid bio-anticlastogenicity. JT CANCER DETECTION AND PREVENTION.

PT JOURNAL-ARTICLE (ART).

AB The protective effects of ascorbic acid (AA), n-acetyl-l-cysteine (NAC), alpha-tocopherol acid (ATA), alpha-tocopherol-acid succinate (TAS), and 13-cis-retinoic acid (CRA) on mutagen-induced chromosomal breakage were studied. Mutagen-sensitivity was determined by the bleomycin assay in human lymphoblastoid cell lines (LCLs) and cultures of peripheral blood lymphocytes (PBLs) from head and neck cancer patients. Preincubation with chemopreventive agents statistically significantly decreased mutagen-induced chromatid breakage in LCLs and PBLs in a dose-related manner. As the concentration of the agents was increased in tenfold increments in the study range, mean breakage rates were reduced by 3.0 to 7.7% in LCLs and by 6.0 to 11.1% in PBLs. The effective concentrations are comparable to those achieved in clinical applications and found in human dietary studies. A similar phenomenon in vivo, if identified, may explain the differences in occurrence of head and neck and other cancers between populations with different dietary habits. The bleomycin assay may be used for studying compounds with presumed chemopreventive properties. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB Inhibitory effects of garlicin and cinnamaldehyde on SOS response and their mechanisms in *Escherichia coli* were investigated. Garlicin and cinnamaldehyde suppressed the lambda cI depended SOS response induced by 4-nitroquinoline-N-oxide (4NQO), mytomycin (MMC) and methyl methane-sulfonate (MMS), and the lexA-depended SOS response induced by 4NQO and UV to various extent, respectively. They also diminished the rexA 441-depended SOS response induced by temperature (at 42 degrees C) However, they did not show any effect on the constitution of SOS functions. It suggested that this inhibitory effect could be via RecA protease which regulates the cleavage of lexA repressor, and perhaps, lambda cI repressor. Author-abstract.

TI Mutagenicity and antimutagenicity of extracts of three spices and a
medicinal plant in Thailand.

SO Mutat-Res. 1993 Nov. 303(3). P 135-42.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Three kinds of spices (caraway, coriander and black pepper seeds) and a medicinal plant called 'tong tak' in Thai (*Baliospermum axillare*, a species of the spurge family) were fractionated into hot water, methanol and hexane extracts. These extracts were not mutagenic for *Salmonella typhimurium* strains TA98 and TA100 by the Ames assay. However, when the extracts were treated with nitrite, samples of the water and methanol extracts were mutagenic for strain TA100 without metabolic activation. The mutagenicity of the nitrite-treated methanol and hot water extracts of black pepper was highest (8380 and 22,200 His+ per 0.1 g of spice powder, respectively), and that of the nitrite-treated hot water extracts of caraway and tong tak was moderate. The hot water extracts were examined for their *antimutagenic* activity against mutagenicity induced by various carcinogens by the Ames assay, using the preincubation technique. The tested samples (equivalent to 1-2 mg of spice powder) reduced the mutagenicity induced by 2.7 nmole (397 ng) of N-methyl-N'-nitro-N-nitrosoguanidine by more than 84%, and that induced by dimethylnitrosamine (1.48 mg) or ICR-170 (10 ng) by 30-60%. However, they did not inhibit the mutagenic activity of 1-nitropyrene, 3-nitrofluoranthene, AF-2, methyl methanesulfonate, N-ethyl-N'-nitro-N-nitrosoguanidine, 2-aminoanthracene, 2-acetylaminofluorene, benzo(a)pyrene or IQ. TI Protective effect of cysteine against X-ray- and bleomycin-induced chromosomal aberrations and cell cycle delay.

SO Mutat-Res. 1993 Dec. 290(2). P 231-8.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB The protective effect of cysteine was studied in muntjac and human lymphocytes in vitro scoring chromosomal aberrations in harlequin stained first cycle metaphases, induced by X-irradiation at G0. Its protective efficiency was also studied against the radiomimetic clastogen, bleomycin, in muntjac cells. 30 micrograms and 1 mg/ml of cysteine were given prior to 2, 3, and 4 Gy, and 2 mg/ml prior to only 4 Gy. 30 micrograms cysteine protected only against deletions in 4 Gy-treated cells while 1 mg protected against deletions by all three doses of X-rays. However, rearrangements were not reduced significantly in any of these, probably due to their low frequency. But when cysteine was increased to 2 mg, both types of aberrations were reduced significantly. This shows that a sufficient number of aberrations and an optimum concentration of the protector are essential for eliciting the best protective effect. This conclusion is further supported by the results of 2 mg cysteine treatment in human lymphocytes which yielded higher frequencies of rearrangements with 2 and 3 Gy X-rays than 4 Gy in muntjac, but had a relatively lower frequency of deletions. Thus the most abundant categories of aberration, i.e., deletions in muntjac and exchanges in humans, were reduced significantly by 2 mg cysteine, associated with a prominent reduction in the frequency of aberrant metaphases. Therefore, the differential protection observed with a low concentration of the protector and an insufficient yield of aberrations induced only indicates protection provided to the most frequent type of aberration by a protector when present in lower concentration. Cysteine pretreatment yielded weak protection against the effects of bleomycin, but posttreatment caused a mild potentiation of the clastogenic effect of BLM without altering the cell cycle kinetics. In this context, an action of cysteine as a reducing agent on BLM is suggested. Although cysteine alone caused severe retardation of the cell cycle, when given prior to X-irradiation, not only its delaying effect was not observed, but also it reduced the X-ray-induced cell cycle delay. This might be due to the oxidation of cysteine by its radical scavenging action. Author-abstract.

TI Porphyrins as potential inhibitors against exposure to carcinogens and mutagens.

SO Mutat-Res. 1993 Nov. 290(1). P 79-85.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).

AB Studies have shown that there are many substances that can interfere with the actions of carcinogens and mutagens. Porphyrins, which often are constituents of diet, are a class of such inhibitors. Hemin can inhibit selectively the activity of mutagens having polycyclic structures by forming complexes with them. These effects were found with the use of bacterial assays and also by in vitro chemical experiments. A survey of porphyrins for similar effects has been done in our laboratory and it was found that chlorophyll and chlorophyllin act like hemin. These green pigments are *antimutagenic* in *Salmonella* and in *Drosophila*. Work from other laboratories also has supported the *antimutagenic* character of chlorophyllin. The possibility of modifying human exposure to carcinogens by use of these porphyrins is discussed. A porphyrin-like molecule, copper phthalocyanine trisulfonate, has been shown to have strong affinity to polycyclic compounds. Blue cotton, a cotton preparation bearing this blue pigment as a covalently bound ligand, has been demonstrated to be an adsorbent useful for isolating heterocyclic amines from food and other materials. TI Paracetamol inhibits UV-induced DNA repair in resting human mononuclear blood cells in vitro.

SO Mutagenesis. 1993 Sep. 8(5). P 423-9.

JT MUTAGENESIS.

PT JOURNAL-ARTICLE (ART).

AB The effects of paracetamol on the repair of DNA damage in resting human peripheral mononuclear blood cells (MNC) in vitro were investigated by means of the alkaline elution technique. Low doses of UV light (254 nm, 3 J/m²) caused a transient increase in the amount of DNA single-strand breaks and alkali-labile sites (SSBs). Paracetamol (0.1-1.0 mM) present during post-irradiation incubation approximately doubled the maximum level of UV-induced (1-3 J/m²) SSBs and delayed the completion of repair. Although there were considerable variations between cells prepared from different donors, the level of UV-induced DNA SSBs was always higher with paracetamol. Hydroxyurea (0.3 mM), an inhibitor of ribonucleotide reductase, caused a similar increased accumulation and slow removal of SSBs, whereas cytosine-1-beta-D-arabinofuranoside (Ara C) (10 microM), an inhibitor of DNA polymerases, led to a steady accumulation of DNA SSBs. The increased levels of SSBs caused by paracetamol or hydroxyurea were both completely suppressed by concomitant addition of deoxyribonucleosides; this supports the notion that paracetamol as well as hydroxyurea inhibits ribonucleotide reductase. About the same rates of formation and removal of UV-induced SSBs were observed in T lymphocytes, B lymphocytes and monocytes. In both isolated T lymphocytes and B lymphocytes, paracetamol (0.3 mM) markedly

increased the level of DNA SSBs induced by UV, whereas monocytes seemed to be less sensitive to the effect of paracetamol. It is concluded that the inhibition of DNA repair may contribute to the clastogenic effects of paracetamol. Author-abstract.

TI *Antimutagenic* effects of casein and its digestion products.

SO Food-Chem-Toxicol. 1993 Oct. 31(10). P 731-7.

JT FOOD AND CHEMICAL TOXICOLOGY.

PT JOURNAL-ARTICLE (ART).

AB The *antimutagenic* potential of casein was investigated using several mutagens, including some food-related mutagens, and the Salmonella/microsome and Escherichia coli DNA-repair tests. The effect depended on the type of mutagen and the incubation time of casein with the mutagens. Casein was very effective against benzo`a:pyrene, N-methylnitrosourea and nitrosated 4-chloroindole, and was less effective towards sodium azide and N-nitroquinoline-1-oxide (NQO). Preincubation increased the *antimutagenic* potential of casein towards NQO. Heating of casein (up to 20 min at 130 degrees C) did not alter its *antimutagenic* capacity. The effect of pepsin hydrolysis under simulated gastric conditions on the *antimutagenic* capacity of casein was tested with sodium azide and NQO in the Salmonella/microsome test. The peptides formed were separated by ultrafiltration or by isoelectric precipitation of casein, and were characterized by HPLC size-exclusion and Kjeldahl analysis. The *antimutagenic* potential of casein increased with pepsin hydrolysis; this increase was due to the peptides formed and might be explained by a better accessibility of casein peptides for interaction with mutagens. The *antimutagenic* potential of pepsin-hydrolysed casein towards sodium azide was observed over the whole dose-response curve. Author-abstract.

TI Identification of heterogenous *antimutagenic* activities in the extract of edible brown seaweeds, *Laminaria japonica* (Makonbu) and *Undaria pinnatifida* (Wakame) by the umu gene expression system in *Salmonella typhimurium* (TA1535/pSK1002).

SO Mutat-Res. 1993 Oct. 303(2). P 63-70.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB A significant *antimutagenic* activity was found in the hot water-soluble extract from a common edible brown alga, *Laminaria japonica* (Makonbu in Japanese) which showed suppressive effects on umu gene expression of the SOS response against DNA damage in *Salmonella typhimurium* (TA1535/pSK1002). The extract showed a drastic *antimutagenic* activity against 2-acetylaminofluorene (2-AAF)- or 3-amino-1,4-dimethyl-5H-pyrido`4,3-b:indole (Trp-P-1)-induced mutagenesis which requires liver-metabolizing enzymes, whereas the same extract exhibited weak but significant inhibitory effects on N-methyl-N'-nitro-N-nitrosoguanidine (MNNG)- or furylfuramide (AF-2)-induced mutagenesis in the absence of liver-metabolizing enzymes. Among these *antimutagenic* activities, the minor activity was found in the polysaccharide fraction of the extract which showed roughly equal *antimutagenic* activities against all the mutagens tested. The major activity was detected in the nonpolysaccharide fraction which exhibited a relatively strong *antimutagenic* activity against 2-AAF- or Trp-P-1-induced mutagenesis but a weak activity against MNNG- or AF-2-induced mutagenesis. The nonpolysaccharide fraction was further separated into high- or low-molecular-weight fractions and the latter fraction showed a much stronger activity than the former fraction. In addition, similar *antimutagenic* activities were detected in polysaccharide and nonpolysaccharide fractions from the extract of the other edible brown alga, *Undaria pinnatifida* (Wakame in Japanese). These experimental results indicate that the hot water-soluble extract of *Laminaria japonica* or *Undaria pinnatifida* contains heterogenous *antimutagenic* activities against typical genotoxic substances. The significance of this finding is discussed from the viewpoint of the protection against genotoxic substances by traditional edible seaweeds in Japan. Author-abstract.

TI Mutagenic activity of urban air samples and its modulation by chili extracts.

SO Mutat-Res. 1993 Oct. 303(2). P 55-61.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Different samples of ambient particulate organic matter were collected during the summer and winter of 1990 in Mexico City. After dichloromethane extraction, the samples were tested for mutagenicity with derivatives of *Salmonella typhimurium* possessing high activity of 'classical' nitroreductase (YG1021) or O-acetyltransferase (YG1024), and compared to the mutagenicity of the normal strain YG1020, and to that of a nitroreductase-deficient mutant TA98NR. The two enzyme-overproducing strains were more sensitive to the mutagenic effect of the extracts than the parent and deficient strains. The sensitivity order, i.e., YG1024 > YG1021 > YG1020 > TA98NR, emphasizes the usefulness of the new *Salmonella* strains in analyzing the mutagenicity of complex mixtures and suggests that some of the direct mutagenic compounds in the urban air samples are nitro-aromatics. Investigations were also conducted to analyze the effect of chili extract on the mutagenicity of an urban air sample. The extract itself showed moderate mutagenic activity and an additive effect was noted when both the chili and air extracts were present. On the other hand, the maximum volume of chili tested produced a decrease in the number of revertants without affecting the background lawn of bacterial growth. The same response was also observed when 1-nitropyrene, 1,6-dinitropyrene or 1,8-dinitropyrene was used as the genotoxic compound, although potentiation instead of addition occurred at low vegetable volumes. At the concentrations found in the chili extract, chlorophyllin and beta-carotene showed an *antimutagenic* effect against the nitro-aromatic compounds. Author-abstract.

TI *Antimutagenic* potency of chlorophyllin in the *Salmonella* assay and its correlation with binding constants of mutagen-inhibitor complexes.

SO Environ-Mol-Mutagen. 1993. 22(3). P 164-71.

JT ENVIRONMENTAL AND MOLECULAR MUTAGENESIS.

PT JOURNAL-ARTICLE (ART).

AB Chlorophyllin (CHL) is a water-soluble salt of chlorophyll that exhibits *antimutagenic* activity in short-term genotoxicity assays and inhibits carcinogen-DNA binding in vivo. The *antimutagenic* potency of CHL was studied against several structurally related heterocyclic amines using the *Salmonella* assay. The mutagens included 2-amino-3-methylimidazo[4,5-f]quinoline (IQ) and seven related IQ-type compounds, and 3-amino-1-methyl-5H-pyrido[4,3-b]indole (Trp-P-2) and three additional non-IQ-type compounds. No relationship was observed between mutagenic potency (revertants/ng mutagen) and *antimutagenic* potency when expressed in terms of the CHL

dose/plate-inhibiting mutagenicity by 50 percent (I50). However, a correlation was observed between mutagenic potency and the mole ratio of CHL to mutagen giving 50% inhibition (MR50), with most mutagens requiring several hundredfold to several thousandfold molar excess of CHL for inhibition. In spectrophotometric studies, CHL formed noncovalent molecular complexes with the heterocyclic amines, with binding constants in the range $3\text{--}13 \times 10^3 \text{ M}^{-1}$. Binding constants were inversely correlated with I50 and MR50 values, i.e., with increasing strength of complex formation less CHL/plate and a lower mole ratio of CHL to mutagen was required to inhibit mutagenicity. The results support an inhibitory mechanism in which chlorophylls operate as "interceptor molecules," interacting with carcinogens and mutagens directly and limiting their bioavailability.

TI Modulation of the H2O2-induced SOS response in *Escherichia coli* PQ300 by amino acids, metal chelators, antioxidants, and scavengers of reactive oxygen species.

SO Environ-Mol-Mutagen. 1993. 22(3). P 157-63.

JT ENVIRONMENTAL AND MOLECULAR MUTAGENESIS.

PT JOURNAL-ARTICLE (ART).

AB The SOS chromotest is a simple colorimetric genotoxicity assay that monitors DNA repair by measuring the induction of the gene *sfia* in *Escherichia coli* K-12. *E. coli* PQ300, a diagnostic SOS tester strain for the detection of oxidative genotoxins, carries a mutation in a key gene for antioxidative defense, *oxyR*. This mutation renders PQ300 more sensitive to oxidative genotoxins, particularly to H2O2. We found that induction of the SOS response by H2O2 in *E. coli* PQ300 is dependent on the composition of the incubation medium; a substantially reduced response was obtained in minimal phosphate buffered saline (PBS) as opposed to complex Luria broth (LB) medium. Supplementation of PBS with histidine or cysteine stimulated H2O2-induced SOS induction to levels exceeding those found in LB medium. Low concentrations of glutathione (20-70 microM) also enhanced the H2O2-induced SOS response in *E. coli* PQ300, whereas higher concentrations (> 150 microM) were protective. Preincubation of tester cells with the chelators o-phenanthroline, 2,2-dipyridyl, and ethylenediaminetetraacetic acid (EDTA) protected cells from the effects of H2O2, although EDTA was only partially effective. Pretreatment of PQ300 with the antioxidant ascorbic acid or the hydroxyl radical scavenger dimethyl sulfoxide also diminished the SOS response, whereas mannitol and glucose were ineffective. The results show that the net effect of H2O2-induced DNA damage is influenced by the balance of oxidative and antioxidative factors and, furthermore, can be modulated by constituents of the extracellular milieu.

PT JOURNAL-ARTICLE (ART).

AB We have analyzed the mutagenic effect of elevated temperatures (hyperthermia: HT) either upon direct exposure or after a previous heat shock (HS) in the haploid auxotrophic *Saccharomyces cerevisiae* strain SC7K lys2-3 in the logarithmic phase of growth. We demonstrated a significant *antimutagenic* effect of HS (38 degrees C for 1 h) followed by hyperthermia (48 degrees C, up to 60 min). Using cycloheximide (CHM) during the HS exposure we reversed the *antimutagenic* effect. We suggest that, upon HS, the enzymes involved in repair of premutational damage are more resistant to denaturation, i.e., by the induced HSP genes, and could work efficiently to prevent damage fixation in critical targets. CHM blocks the *antimutagenic* effect of the HS treatment by inhibiting the inducible synthesis of HSP. Author-abstract.

AB The incidence of chromosome aberrations (CAs) was investigated in cultured lymphocytes of 109 styrene-, formaldehyde-, and phenol-exposed workers in comparison with 64 controls. There was a marked increase in the incidence of the structural chromosome aberrations in the first mitotic division metaphases of occupationally exposed workers (3.59 +/- 0.26 CAs/100 cells vs 1.47 +/- 0.14 in controls (P < 0.01). 22 occupationally-exposed workers were selected for the trial including 1-month administration of a drug Aevitum (100,000 U of retinol palmitate plus 0.1 g of alpha-tocopherol acetate dissolved in 0.2 ml of oil) at a daily dose of 1-2 capsules for 5 days a week. The frequency of chromosome aberrations before, after the administration of a cumulative Aevitum dose of 2.0, 4.0 and 8.0 ml, and 6 weeks after the cessation of vitamin intake was 5.68 +/- 0.63, 4.33 +/- 0.45, 2.67 +/- 0.34, 2.00 +/- 0.25, and 2.64 +/- 0.21 per 100 cells, respectively. Thus, Aevitum was found to cause a significant decrease in

occupationally-induced chromosome damage in human lymphocytes.

 AB *Oldenlandia diffusa* (OD) and *Scutellaria barbata* (SB) have been used in traditional Chinese medicine for treating liver, lung and rectal tumours. We previously showed that they inhibited mutagenesis, DNA binding and metabolism of aflatoxin B1 (AFB1) and benzo(a)pyrene (BaP) bioactivated by Aroclor 1254-induced rat S9. The purpose of this study was to investigate the effects of OD and SB on the mutagenicity of AFB1 in *Salmonella typhimurium* TA100 using dexamethasone (DXM)-induced rat hepatic S9, on cytochrome P450-linked aminopyrine N-demethylase (APND) activity in DXM-induced hepatic microsomes and on the metabolism of AFB1 by DXM-induced S9 using high-performance liquid chromatography (HPLC). The experimental results showed that OD and SB consistently inhibited the mutagenicity of AFB1 bioactivated by either non-induced or DXM-induced S9. These effects correlated with the inhibition of cytochrome P450-linked APND activity in DXM-induced microsomes and with an inhibition of DXM-induced S9 mediated metabolism of ³H:AFB1 as determined by HPLC. Since DXM treatment has been associated with an induction of the CYP3 enzyme family, these results suggest that OD and SB may possess *antimutagenic* and antitumorigenic activity towards AFB1 through an inhibition of CYP3-mediated metabolism of AFB1. JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB The effect of pretreatment with sulfoethylglucan (SEG) on the frequency of micronuclei and the liver alkaline phosphatase activity induced by potassium bichromate (Cr(VI)) in mice was evaluated. Simultaneous application of SEG and Cr(VI) decreased the frequency of micronuclei in bone marrow cells ($P < 0.01$) and the level of liver alkaline phosphatase activity in comparison to the Cr(VI) group. Pretreatment with SEG 24 h prior to the first Cr(VI) application resulted in a more pronounced decrease in the Cr(VI)-induced frequency of micronuclei. The mechanisms of the protective effects of sulfoethylglucan could be explained either by the formation of Cr ion complexes with sulfoethyl groups of glucan or by the scavenging ability of SEG to trap hydroxyl radicals. TI Effect of turmeric on xenobiotic metabolising enzymes.

SO Plant-Foods-Hum-Nutr. 1993 Jul. 44(1). P 87-92.

JT PLANT FOODS FOR HUMAN NUTRITION.

PT JOURNAL-ARTICLE (ART).

AB Diet contains several substances capable of inhibiting chemical carcinogenesis. It is known that such inhibitors may either act directly by scavenging the reactive substances or indirectly by promoting mechanisms which enhance detoxification. Turmeric which contains curcumin both in vitro and in vivo is an active *antimutagen.* Studies were therefore conducted to evaluate the effects of turmeric on xenobiotic metabolising enzymes in hepatic tissue of rats fed turmeric ranging from 0.5-10% in the diet. Enzymes such as aryl hydrocarbon hydroxylase, UDP glucuronyl transferase and glutathione-S-transferase were assayed after four weeks of turmeric fed diets. No significant differences were seen in the activating enzyme AHH. However, UDPGT was significantly elevated in rats fed 10% turmeric while GSHT registered a significant increase in 5 and 10% turmeric fed diet as compared to controls and 0.5-1.0% turmeric fed animals. The results suggest that turmeric may increase detoxification systems in addition to its anti-oxidant properties. Curcumin perhaps is the active principle in turmeric. Turmeric used widely as a spice would probably mitigate the effects of several dietary carcinogens. Author-abstract.

JT CRITICAL REVIEWS IN TOXICOLOGY.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).

AB The number of studies in the research field of antimutagenesis is increasing. The aims of many of these studies are preventing genetic hazards from environmental mutagens and elucidating the process of mutagenesis. Some naturally occurring flavorings such as vanillin, cinnamaldehyde, and coumarin have been reported to inhibit mutagenesis induced by mutagens in bacterial and mammalian cells. These flavorings are considered to act as *antimutagens* by modifying DNA replication and/or DNA repair systems after cellular DNA was damaged by mutagens. A factor that suppresses mutagenicity in a given situation, however, sometimes exerts enhancing effects when the endpoints investigated or the test conditions used are varied. This makes the evaluation of *antimutagenic* factors complicated. Different modifying effects of the above-mentioned flavorings observed in various test systems for genotoxicity are discussed, based on their proposed mechanisms. Author-abstract. 78 Refs.

TI Sister-chromatid exchanges induced by trihalomethanes in rat erythroblastic cells and their suppression by crude catechin extracted from green tea.

SO Mutat-Res. 1993 Aug. 300(3-4). P 241-6.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB An in vitro sister-chromatid exchange (SCE) assay using rat erythroblastic leukemia cells was conducted with four major trihalomethanes (THMs): chloroform, CHCl₃; dichlorobromomethane, CHCl₂Br, dibromochloromethane, CHClBr₂; bromoform, CHBr₃. In the absence of S9 mix, CHBr₃, CHClBr₂ and CHCl₂Br significantly induced SCEs in a clear dose-dependent manner, while CHCl₃ did not significantly induce SCEs. On the other hand, the incidence of CHCl₃-induced SCEs significantly increased, although the incidence of CHBr₃-induced SCEs decreased by the addition of S9 mix. However, there was no difference between the incidence of SCEs induced by CHBr₃, CHClBr₂ or CHCl₂Br in the absence of S9 mix and that in the presence of S9 mix. The addition of crude catechin to the SCE assay system suppressed the ability of CHCl₃ or CHBr₃ to induce SCEs but had no suppressive effect on the other THM-induced SCEs. The suppression of SCEs induced by CHCl₃ or CHBr₃ depended on the crude catechin dose. Author-abstract.

TI The genotoxicity of the waste water discharged from paraquat manufacturing and its pyridyl components.

SO Mutat-Res. 1993 Aug. 300(3-4). P 223-9.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB The genotoxic potencies of waste water condensate from paraquat manufacturing and its pyridyl components on V79 cells were evaluated using the alkaline elution assay and 6-thioguanine resistance mutation assay. Although 2,2'-dipyridyl and 2,2',2''-tripyridyl both were highly cytotoxic to the cells, only 2,2'-dipyridyl induced moderate DNA-cleaving activity and a low frequency of thioguanine resistance mutation in V79 cells. However, equally toxic doses of waste water condensate exhibited highly DNA-damaging and mutagenic activities in the same cell system. After chelation of ferrous ions, the number of DNA lesions and frequency of 6-TGr mutations induced by waste water condensate were slightly suppressed, whereas by contrast those induced by 2,2'-dipyridyl were significantly potentiated. These results indicate that the coordination compound formation of pyridyl derivatives of waste water with metal ions, especially ferrous ions, in biological systems may be closely related to these genotoxic mechanisms. Finally, it was found that DMSO (a scavenger of hydroxyl radical) and catalase could remarkably protect cells from genotoxic damage induced by waste water condensate, 2,2'-dipyridyl and their ferrous complexes, but this protection was not observed in cells which were treated with SOD (superoxide dismutase). This suggests that the generation of some unknown active oxygen species may be involved in the genotoxic mechanisms of waste water condensate and its constituent 2,2'-dipyridyl. Author-abstract.

TI Effect of human and recombinant IFN-alpha and IFN-beta on the sister-chromatid exchange (SCE) frequency in amniotic fluid cells in vitro.

SO Mutat-Res. 1993 Aug. 300(3-4). P 195-200.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Sister-chromatid exchange (SCE) and rates of proliferation in human amniotic fluid cells from healthy donors exposed to human IFN-alpha and IFN-beta and recombinant IFN-alpha and -beta were investigated. Amniotic fluid cells were obtained from pregnant women undergoing genetic amniocentesis. For 46 h, cells were treated with IFNs at concentrations of 10(3)-10(5) U/l. A dose-depending decrease of SCE rate with IFN-alpha and IFN-beta was observed. Our studies in amniotic fluid cells show that the mean SCE frequencies are reduced after incubation with IFN-alpha as well as with IFN-beta. In contrast to IFN-gamma, the type I IFNs IFN-alpha and IFN-beta cause a genetic effect on DNA repair or a protection from DNA damage. Previously we had shown that a significant dose-depending increase of SCE rates was found in amniotic fluid cultures after addition of IFN-gamma. Therefore, IFN-alpha and IFN-beta (both human IFNs) and also recombinant IFN-alpha and IFN-beta, also in high doses, are neither genotoxic/clastogenic nor embryotoxic. Amniotic cells are vulnerable human cells, which may be well suited for examining the effects of agents like interferon. Author-abstract.

TI Antimutagenicity of cyclohexanol towards 4-(N-nitrosomethylamino)-1-(3-pyridyl)-1-butanone and N-nitrosodiethylamine in Salmonella typhimurium strain TA100.

SO Mutat-Res. 1993 Aug. 300(3-4). P 151-4.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB The ability of cyclohexanol to inhibit the mutagenicity of tobacco-specific nitrosamine 4-(N-nitrosomethylamino)-1-(3-pyridyl)-1-butanone (NNK) and of N-nitrosodiethylamine (NDEA) was tested on *Salmonella typhimurium* strain TA100. Cyclohexanol produced a dose-dependent decrease in the number of revertants induced by a single dose of NNK (24 mumoles) or NDEA (59 mumoles). Nevertheless, this inhibitory effect was not observed with other premutagenic agents such as benzo`a:pyrene and 2-aminoanthracene nor with direct mutagens such as ethyl methanesulfonate and methyl methanesulfonate. These results suggest that cyclohexanol interferes with the 'bioactivation' of the tested nitrosamines in a similar way that other alcohols such as ethanol or isopropanol interfere with N-nitro-sodimethylamine and NDEA metabolism. Author-abstract.

TI Residual mercury in seed of barley (*Hordeum vulgare* L.) confers genotoxic adaptation to ethyl methanesulfonate, maleic hydrazide, methyl mercuric chloride and mercury-contaminated soil.

SO Mutat-Res. 1993 Aug. 300(3-4). P 141-9.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Seeds of barley, *Hordeum vulgare* L., with or without residual mercury were exposed to concentrations of ethyl methanesulfonate (EMS), maleic hydrazide (MH), methyl mercuric chloride (MMCl) and mercury-contaminated soil. Subsequently the endpoints measured were germination, seedling height, mitotic index, mitotic chromosome or spindle aberrations in embryonic shoot cells and meiotic chromosome aberration in pollen mother cells. The results unequivocally demonstrated that the seed-residual mercury conferred protection against the genotoxicity of EMS, MH, MMCl as well as mercury-contaminated soil in barley. The genotoxic adaptation to MH and MMCl was significantly prevented by pre-exposing the Hg-seeds to buthionine sulfoximine, an inhibitor of phytochelatin synthesis. Furthermore, compared to normal seedlings, the seedlings grown from Hg-seeds exhibited a higher amount of non-protein SH. The findings indicated a possible involvement of phytochelatins in the mercury-induced adaptive response. Author-abstract.

TI Suppressing effects of S phase post-treatment with carbolines on sister-chromatid exchanges induced by mitomycin C in Chinese hamster

cells.

SO Mutat-Res. 1993 Jul. 302(3). P 165-71.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB The effects of post-treatment with four types of carbolines-alpha-, beta-, gamma-, and delta-carbolines-and aminoimidazoazaarenes during S phase on the frequency of SCEs induced by MMC were studied in synchronized Chinese hamster CHO cells. Post-treatment with alpha-carbolines (A alpha C, MeA alpha C), beta-carbolines (harman, norharman, harmine, and harmaline), gamma-carbolines (Trp-P-1 and Trp-P-2) and delta-carbolines (Glu-P-1, and Glu-P-2) during S phase at non-clastogenic concentrations caused a statistically significant decrease in the frequency of SCEs induced by MMC. Aminoimidazoazaarenes (IQ, MeIQ, and diMeIQx) showed no effects on SCEs, suggesting that the SCE-suppressing activity resides in the carboline structure. The data suggest that the suppressing effect may be due to inhibition of DNA replication. Author-abstract.

TI Strong inhibition of 2-amino-6-methyldipyrido`1,2-a:3',2'-d: imidazole-induced mutagenesis and hepatocarcinogenesis by 1-O-hexyl-2,3,5-trimethylhydroquinone.

SO Jpn-J-Cancer-Res. 1993 May. 84(5). P 481-4.

JT JAPANESE JOURNAL OF CANCER RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB The effects of 3-O-dodecylcarbomethylascorbic acid (3-O-DAsA), 3-O-ethylascorbic acid (3-O-EAsA) and 1-O-hexyl-2,3,5-trimethylhydroquinone (HTHQ) on 2-amino-6-methyldipyrido`1,2-a:3',2'-d:-imidazole (Glu-P-1)-induced mutagenesis and hepatocarcinogenesis were examined. In a Salmonella assay, addition of 2.5 to 20.0 mg of HTHQ to Salmonella TA 98 in the presence of S-9 mixture dose-dependently inhibited Glu-P-1-induced mutagenesis. The highest dose showed a 99% reduction in revertants. 3-O-DAsA and 3-O-EAsA were without effect. In an animal study using the medium-term bioassay system for the detection of hepatocarcinogens or hepatopromoters in F344 male rats, treatment with Glu-P-1 alone was associated with a significant increase in the number and area of GST-P-positive foci (47.5 +/- 8.9 and 11.1 +/- 4.7, respectively). Combined treatment with 1.0% HTHQ significantly reduced the number and area of GST-P-positive foci (to 8.1 +/- 2.1 and 0.6 +/- 0.2) while 3-O-DAsA exerted marginal inhibition and 3-O-EAsA had no effect. On the other hand, all three of these compounds slightly enhanced the numbers and areas of foci when given alone. The results indicate that HTHQ is a potent chemopreventer of Glu-P-1-induced hepatocarcinogenesis. Author-abstract.

TI Interaction of pine cone extract fraction VI with mutagens.

SO Mutat-Res. 1993 Jul. 297(1). P 53-60.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Pine cone extract fraction VI (PC-VI) inhibited the mutagenicity of the promutagens tested: the polycyclic aromatic hydrocarbon benzo(a)pyrene (B(a)P) dose-dependently, and the aromatic amines 2-aminoanthracene (AA) and 2-acetylaminofluorene (AAF) at high concentrations. PC-VI had no effect on the mutagenicity of the direct-acting mutagens 2-(2-furyl)-3-(5-nitrofuryl)acrylamide (AF-2) and N-methyl-N'-nitro-N-nitrosoguanidine (MNNG), but inhibited the mutagenicity of the direct-acting mutagen N-hydroxy 2-acetylaminofluorene (N-OH AAF, proximate mutagen of AAF). The addition of PC-VI to rat hepatic microsomes resulted in a decrease of their enzyme activities, especially NADPH-cytochrome c reductase. By gas-chromatographic analysis of B(a)P or AA contents after incubation of B(a)P or AA and PC-VI and S9 mix, the inhibition of hepatic metabolizing enzymes and the interaction between AA and PC-VI were confirmed. On the other hand, PC-VI had no effect on the DNA repair systems for B(a)P- or AA-induced mutagenesis. We conclude that PC-VI shows indirect antimutagenicity by interfering with cytochrome P-450-dependent bioactivation and by direct interaction with AA and the proximate mutagenic product of AAF. TI N-(4-hydroxyphenyl) retinamide is anticlastogenic in human lymphoblastoid cell lines.

SO Anticancer-Res. 1993 Mar-Apr. 13(2). P 355-6.

JT ANTICANCER RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB The in vitro anticlastogenic effects of a new synthetic retinoid derivative, N-(4-hydroxyphenyl)-retinamide (4-HPR), were studied in two human lymphoblastoid cell lines (3640P and 4087P). Cell cultures were preincubated with 4-HPR in a range of concentrations from 10^{-9} to 10^{-6} M for 24 h. The number of chromatid breaks per cell (b/c) induced by a 2-hour treatment with 0.004 U/ml bleomycin was determined. The mean b/c values in cell cultures treated with bleomycin alone were 0.50 (3640P) and 0.73 (4087P). The presence of 10^{-6} M 4-HPR significantly decreased this value in both cell lines to 0.27 in 3640P ($p < 0.01$) and 0.41 in 4087P ($p < 0.05$). Lower

concentrations (10^{-7} and 10^{-8} M) of 4-HPR significantly decreased b/c only in cell line 3649 ($p < 0.05$). Incubation with the lowest concentration (10^{-9} M) of 4-HPR did not decrease b/c values. These preliminary data demonstrate that 4-HPR has anticlastogenic effects in vitro and are similar to our results from previous studies on the in vitro antigenotoxic effects of 13-cis-retinoic acid (Trizna Z et al, Eur J Cancer, 1993, 29A: 137-140). JT ANNALS OF THE NEW YORK ACADEMY OF SCIENCES.
PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).
AB Many studies have now indicated that micronutrients, such as the carotenoids, tocopherols, and ascorbic acid, can prevent mutagenesis, genotoxic effects, or malignant transformation in bacteria and mammalian tissue, either in cell culture or in organ culture. In addition, multiple papers report that some of these micronutrients act as anticarcinogenic agents in animals treated with either ultraviolet light, ultraviolet light with chemicals, or chemical carcinogens alone. With respect to the carotenoids, early experiments used pharmacological doses of carotenoids, but more recent reports indicate that relatively small doses can be effective.

Inasmuch as these effects are seen with both provitamin A and nonprovitamin A carotenoids, it would appear that these effects are intrinsic to the carotenoid molecule, and not due to the metabolic conversion to retinoids. Partially on the basis of these observations, it has been suggested that the micronutrients may function as chemopreventive agents for reducing the risk of cancer in humans. Numerous human intervention studies are underway to test this hypothesis. Author-abstract. 65 Refs.

TI Binding of polycyclic planar mutagens to chlorophyllin resulting in inhibition of the mutagenic activity.

SO Mutat-Res. 1993 Jun. 287(2). P 293-305.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Chlorophyllin is known to inhibit the mutagenicity of a variety of compounds. Using highly purified samples of chlorophyllin and its family compounds, we studied the mechanism of the inhibition. Since mutagens with polycyclic planar structures are particularly strongly inhibited, it seemed likely that the inhibition arises by trapping of the mutagens by chlorophyllin through complex formation at the planar surfaces of these molecules. To explore this possibility, we prepared a Sepharose bearing covalently linked chlorophyllin as ligand, and the adsorption of mutagens to this Sepharose was measured. Three different chlorophyllin derivatives were used, i.e., copper-chlorin, iron-chlorin and chlorin, to investigate the role of metal in the center of the chlorophyllin chromophore. Adsorption of 37 different compounds, mostly mutagens, in 0.02 M Tris-HCl buffer at pH 8.0 to these chlorophyllin-Sepharose preparations was studied in a quantitative manner. The results showed that most of the compounds having three or more fused rings were strongly adsorbed with apparent dissociation constants of 10^{-5} - 10^{-6} M, whereas those having two fused rings or one ring were only poorly adsorbed. Since the three Sepharose adsorbents gave similar adsorption profiles, it appeared that the central metal in the chlorophyllin molecule does not play a crucial role in the adsorption. We also measured the inhibitory effect of copper-chlorin against the mutagenicity of some of these compounds using the Salmonella assay. The results showed that those mutagens that were strongly adsorbable to copper-chlorin-Sepharose were subject to efficient inhibition by copper-chlorin, whereas many of those only poorly adsorbed were inhibited only weakly. We concluded that trapping by complex formation plays a role in the *antimutagenic* actions of chlorophyllin against many mutagens, particularly notable being the actions against ICR-170, quinacrine, aflatoxin B1, Trp-P-1 and Trp-P-2. An unusual behavior of Trp-P-2 in the adsorption process, i.e., a very tight complex formation at an extremely low Trp-P-2 concentration, was found; the implication of

this phenomenon in relation to the real environmental setting is discussed. Author-abstract.

TI *Antimutagenic* effects of flavonoids, chalcones and structurally related compounds on the activity of 2-amino-3-methylimidazo[4,5-f]quinoline (IQ) and other heterocyclic amine mutagens from cooked food.

SO Mutat-Res. 1993 Jun. 287(2). P 261-74.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Sixty-four flavonoids were tested for their *antimutagenic* potencies with respect to IQ in *Salmonella typhimurium* TA98 and in part also towards MeIQ, MeIQx, Trp-P-2, and Glu-P-1 and in *S. typhimurium* TA100. *Antimutagenic* potencies were quantified by the inhibitory dose for 50% reduction of mutagenic activity (ID50). A carbonyl function at C-4 of the flavane nucleus seems to be essential for antimutagenicity: two flavanols and four anthocyanidines were inactive. Again, five isoflavons, except biochanin A, were inactive. Within the other groups of 21 flavones, 16 flavonols and 16 flavanones the parent compounds flavone, flavonol, and flavanone possessed the highest *antimutagenic* potencies (ID50: 4.1, 2.5, 5.5 nmoles). Increasing polarity by introduction of hydroxyl functions reduced *antimutagenic* potency. Reducing polarity of hydroxy flavonoids by methyl etherification, however, increased *antimutagenic* potency again. 6-Hydroxy- and 2'-hydroxy substituted flavonoids were considerably less potent *antimutagens.* Of 11 flavonoid glycosides tested all compounds except apigenin- and luteolin-7-glucoside (ID50:74, 115 nmoles) were inactive or only weakly *antimutagenic.* Rings C and A of the nucleus were not essential for antimutagenicity: chalcone and three derivatives were nearly as active as comparable flavones while antimutagenicity of benzylidenacetone was considerably reduced (ID50: 95 nmoles). Cinnamylaldehyde and cinnamoates, however, were inactive. A planar structure in the vicinity of the carbonyl group may also be important for antimutagenicity. Flavanones were less potent *antimutagens* than the corresponding flavones, but dihydrochalcones and 14 structurally related saturated aromatic carbonyl compounds were inactive. Fisetin and 6-hydroxyflavone were competitive inhibitors, but luteolin was a mixed type inhibitor. The inhibition mechanisms of flavone, kaempferol, morin, flavanone, and 2'-hydroxyflavanone were concentration dependent, being competitive at low concentrations and mixed or non-competitive (2'-hydroxyflavanone) at concentrations about the ID50 value. No fundamental differences between the two tester strains and no clear influence of mutagen structure on *antimutagenic* potency could be detected. Author-abstract.

TI Supplemental dietary calcium fails to alter the acute effects of 1,2-dimethylhydrazine on O6-methylguanine, O6-alkylguanine-DNA alkyltransferase and cellular proliferation in the rat colon.

SO Carcinogenesis. 1993 Jun. 14(6). P 1175-9.

JT CARCINOGENESIS.

PT JOURNAL-ARTICLE (ART).

AB Prior studies from our laboratory have demonstrated that K-ras G to A mutations were detectable in a high percentage of carcinomas which developed in the colons of animals treated with the known colonic procarcinogen, 1,2-dimethyl-hydrazine (DMH). Moreover, in this model, the incidence of these mutations was decreased by a supplemental dietary calcium regimen which concomitantly decreased the frequency of rats with multiple tumors as well as tumor size. In an attempt to clarify the possible mechanism(s) involved in this *antimutagenic* effect of supplemental calcium, two groups of Sprague-Dawley rats were fed semisynthetic diets containing either 0.87 or 1.80% calcium by weight for 3 weeks, s.c. injected with 100 mg/kg of DMH and killed prior to and at various time periods (16-144 h) after injection. The colons of animals were analyzed and compared with respect to O6-methylguanine content in DNA, O6-alkylguanine-DNA alkyltransferase levels as well as cellular proliferation, as assessed by immunohistochemical staining of colonic crypts by bromodeoxyuridine. In certain experiments, these parameters were also analyzed in the proximal and distal colon before and at various times after administration of DMH. The results of these experiments demonstrated that supplemental dietary calcium was not found to influence significantly O6-methylguanine levels, alkyltransferase levels or cellular proliferation in the entire colon or in either colonic segment before or after the acute administration of DMH. DMH did, however, differentially alter all three of these biochemical parameters in the colonic segments (distal > proximal), possibly due to a greater degree of metabolic activation in the distal colon. JT CANCER EPIDEMIOLOGY, BIOMARKERS AND PREVENTION.

PT CONGRESS (CON).

AB This conference, attended by scientists from 27 countries, focused on the most recent advances in the field of antimutagenesis and anticarcinogenesis. Particular emphasis was given to the mechanistic approach, which is believed to be an essential prerequisite for a safer and more effective implementation of chemoprevention of cancer and of mutation-related diseases. The arrangement of the six regular sessions basically followed and updated the detailed classification of mechanisms of inhibitors of mutagenesis and carcinogenesis proposed by S. De Flora and C. Ramel (Mutat. Res., 202: 285-306, 1988), covering both extracellular and cellular mechanisms involved in the prevention of mutations and cancer initiation, as well as in the modulation of later stages of the carcinogenesis process. In addition, a workshop was devoted to methodological aspects concerning the modulation of the genotoxic and carcinogenic response. The present report covers the main themes of overview lectures or research communications presented by more than 60 speakers. Most presentations were multi-authored, as the result of collaborative studies, in several cases at the international level, but only the names of speakers will be given. Author-abstract.

SO Acta-Otorhinolaryngol-Ital. 1992 Sep-Oct. 12(5). P 435-41.

JT ACTA OTORHINOLARYNGOLOGICA ITALICA.

PT JOURNAL-ARTICLE (ART).

AB Radiotherapeutic treatment of patients with carcinoma usually causes genotoxis damage. This has been studied recently using the test of micronuclei in esfoliated cells. This test presents methodologic advantages in compared with the classic citogenetic analysis and as it is carried out on esfoliated cells from the oral cavity it faithfully reflects the genotoxic damage undergone by the cells of the basal layer of the epitelium. The preliminary result obtained so far have confirmed the anticlastogenic activity of beta-carotene in fact, the frequence of micronuclei in esfoliated cells from the oral cavity in patients undergoing radiotherapy or undergoing treatment with beta-carotene is inferior to that of patients undergoing treatment with beta-carotene is inferior to that of patients undergoing radiotherapy without the subministration of carotenoids. Treatment with carotenoids does not influence the therapeutic efficiency of radiotherapy treatment. Therefore, the results seem to confirm that indirect ossidaction processes are involved in the mechanism of the clastogenic action of radiotherapia. The carotenoids seem to be able to contrast validly this undesirable effect without interfering with the desirable therapeutic effect. Author-abstract.

JT ENVIRONMENTAL AND MOLECULAR MUTAGENESIS.

PT JOURNAL-ARTICLE (ART).

AB The anticlastogenic activity of crude extract of garlic (*Allium sativum* L.) was studied in bone marrow cells of mice. Male laboratory-bred Swiss albino mice were given one of three concentrations of the freshly prepared extract (100 mg, 50 mg, and 25 mg/kg body weight) as a dietary supplement by gavage for 6 consecutive days. On the seventh day the mice were administered a single acute dose of two known clastogens, mitomycin C (1.5 mg/kg) and cyclophosphamide (25 mg/kg) or sodium arsenite (2.5 mg/kg), simultaneously with garlic extract. After 24 hr, chromosome preparations were made from the bone marrow cells. The endpoint studied were chromosomal aberrations and damaged cells. Garlic extract alone induced a low level of chromosomal damage. The clastogenicity of all three mutagens were reduced significantly in the animals which had been given garlic extract as dietary supplement. The extent of reduction was different for the three clastogens and may be attributed to the interaction with the different components of the extract. Author-abstract.

SO Mutat-Res. 1993 Jun. 300(1). P 63-72.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Mutagenesis of several insoluble nickel compounds--crystalline nickel sulfide NiS, nickel subsulfide Ni₃S₂, nickel oxides (black and green) and soluble NiCl₂ was studied in three Chinese hamster cell lines--at the hprt gene of the well-defined V79 cell line, and at gpt in two transgenic derivative cell lines G12 and G10. The transgenic cell line G12 responded very strongly to the insoluble Ni compounds, such that the gpt mutagenesis was at least 20 times higher than the spontaneous mutagenesis and in some experiments was even higher. In contrast the response of the G10 cells was much lower--the mutant frequencies only increased 2-3 times over the controls. In V79 cells, NiS and NiO (black) did not induce a mutagenic response at hprt. Soluble NiCl₂ also exhibited no mutagenic activity in V79 cells and induced considerably lower activity than the insoluble compounds in the transgenic G12 cells. Following vitamin E pretreatment of G12 cells for 24 h prior to nickel exposure, increased cell survival was observed for several insoluble Ni compounds whereas vitamin E had no effect on NiCl₂ cytotoxicity. With vitamin E pretreatment, significantly lower mutagenic responses in G12 cells were also noted for some insoluble Ni compounds, while no such effect was observed for NiCl₂. Author-abstract.

AB The paper deals with the mechanisms of anticlastogenesis protection of chromosomes in cultured human cells, which depend on many external and internal factors and may vary in genetic risk groups and in individuals. It also analyzes the role of repair and metabolic disturbances in the observed inter- and intragroup differences in the efficiency of protective action in model test systems. Results of comparative analysis of the efficiency of various interferons in the cultured cells from patients with bronchial asthma are presented. The paper first provides evidence for attenuated protective effects in the cultured lymphocytes from patients with xeroderma pigmentosum or chronic recurrent urticaria as compared to those from healthy donors. Prospects of and optimal methodological approaches to the study of anticlastogenesis in human cells are discussed. Author-abstract. 27 Refs.

AB The problems of anticarcinogenesis are discussed in the context of mechanistic approaches and the well-known mechanisms of multistage carcinogenesis. Various events at extra- and intracellular levels are involved in mutagenesis and carcinogenesis. The most promising candidates for suppression of chemical carcinogenesis are some nitrosation modifiers, dietary sorbents, metabolic activation modulators, reactive metabolite trappers, repair inducers, gene expression inhibitors, etc. Short-term tests for mutagenicity are more preferable for screening potential anticarcinogenic agents. The bioassays for anticarcinogenesis should be assessed for sensitivity, specificity and predictability and the genetic profiles of the

antimutagenic activity of the modifiers analysed. Author-abstract.

AB The concept that antimutagenesis is a normal genetic process whose function is to ensure integrity and stability of hereditary structures has been formulated and substantiated. The phenomenon of antimutagenesis is realized by the *antimutagenic* cell system, forming the first level of DNA protection from the mutagenic influences of endogenous and exogenous agents. Repair systems constitute the second protective level. The common mechanism of the protective action of exogenous *antimutagens* is that they act through the *antimutagenic* system components and/or the repair systems. The resistance of organisms to external factors and damaged to their cell systems is determined by a set of components and the intensity of *antimutagenic* and repair functioning. AB To design protectants of human genomic structures against mutagenic effects is defined as a new pharmacological problem; the perspectives of its solution are outlined. The experimental evidence that formed the biological basis for searching for pharmacological correctors of the mutagenic effects produced by xenobiotics is analysed, the basic principles for designing pharmacological protectants of genetic structures are formulated. Great emphasis is laid on the *antimutagenic* properties of antiradical agents. Evidence is provided for that there are no prospects of searching for pharmacological protectants among natural and synthetic phenol compounds. It is noted that the informative value of microbiological tests is poor. To design a corrector of the damaging action of each particular mutagen is shown to be an independent scientific problem which can be solved only by employing eukaryotic test systems. The areas of possible application of *antimutagens* are defined and some known examples of their use to protect human genetic structures are presented. Author-abstract. 119 Refs.

AB Carotenoid (CARs: beta-carotene BC and/or canthaxanthin CX) supplementation have been shown to be chemopreventive in animals, since 1980, against direct or indirect chemical

carcinogenesis/photo-carcinogenesis of the skin, breast, stomach, salivary glands, colon-rectum, urinary bladder, and against transplanted tumors. This action could be either independent of or dependent on pro-vitamin A activity of BC. In vitro, both BC and CX proved to be *antimutagenic* and to have anti-malignant transformation properties in cell cultures. Preliminary interventions in humans with BC +/- CX prevented the onset of second primary tumors in lung, colon, urinary bladder, and head and neck. The powerful antioxidant properties of CARs, possibly associated with their retinoid potential, played a role in all the above observations, producing free-radical quenching and immunostimulation.(ABSTRACT TRUNCATED AT 250 WORDS). PT JOURNAL-ARTICLE (ART).

AB The identification of desmutagens and bioantimutagens in plants has prompted the search for additional plant extracts capable of modifying adverse cellular effects of environmental toxicants. The protective action of crude extracts of *Phyllanthus emblica* fruits (PFE) against lead (Pb) and aluminium (Al)-induced sister chromatid exchanges (SCEs) was studied in bone marrow cells of *Mus musculus*. The modifying effect of the crude extract was compared with that of comparable amounts of synthetic ascorbic acid (AA), a major component of the fruits. Oral administration of PFE or AA for 7 consecutive days before exposure of mice to the metals by intraperitoneal injections reduced the frequencies of SCEs induced by both metals. PFE afforded a more pronounced protective effect than AA in counteracting the genotoxicity induced by both Al and Pb: This difference was significant with Pb. The higher protection afforded by PFE may be attributed to the interaction of AA with other natural ingredients present in the crude fruit extract. Author-abstract.

JT ENVIRONMENTAL AND MOLECULAR MUTAGENESIS.

PT JOURNAL-ARTICLE (ART).

AB Reactive oxygen species were generated in the gas phase by photosensitization involving illumination of Rose Bengal. Depending on whether the chromophore is dry or solubilized, this system produces either energy-transfer reactions leading to generation of singlet oxygen specifically, or a combination of energy-transfer and electron-transfer reactions, providing both singlet oxygen and reduced forms of oxygen, such as superoxide anion and hydrogen peroxide. In neither case were the reactive species mutagenic in strain TA104 of *Salmonella typhimurium*, which had been previously shown to be reverted by oxygen species generated by the hypoxanthine-xanthine oxidase system in aqueous medium. However, mixed oxygen species induced an increased lethality in a variety of DNA repair-deficient *Escherichia coli* strains. This genotoxic effect, mainly reparable by the *uvrA* and *recA* mechanisms, was efficiently prevented by the thiol N-acetyl-L-cysteine. Singlet oxygen itself failed to exert direct genotoxic effects, although secondary reactants produced by its reaction with cell components enhanced lethality in some repair-deficient bacteria. Distance-dependence analyses provided measurements of the lifetimes of the oxygen species generated in the gas phase. Author-abstract.

JT MUTATION RESEARCH.
PT JOURNAL-ARTICLE (ART).
AB A novel *antimutagenic* factor, BA-2, active against UV-induced mutagenesis in *Escherichia coli* WP2 was isolated from the metabolites of *Streptomyces* sp. strain AJ9455. BA-2 also suppressed mutations induced by 4-nitroquinoline N-oxide (4-NQO) and furylfuramide (AF-2) in *E. coli* WP2s (*uvrA*) without any decrease of cellular viability. BA-2 strongly inhibited the UV induction of SOS repair functions when it was monitored by beta-galactosidase activity expressed from the *sulA::lacZ* fusion gene of strain PQ37. It is assumed that the *antimutagenic* effect of BA-2 on mutagenesis induced by UV, 4-NQO or AF-2 was the result of inhibition of induction of the inducible error-prone SOS repair. The structure of BA-2 was considered to be N-methyl-valyl-amiclenomycin, and the structural unit of 4-amino-2,5-cyclohexadiene must be essential for the *antimutagenic* activity, since deamination by heating results in the loss of *antimutagenic* activity of BA-2. TI The clastogen-suppressing effects of green tea, Po-lei tea and Rooibos tea in CHO cells and mice.

SO Mutat-Res. 1993 Apr. 286(2). P 221-32.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB The suppressing effects of crude extracts of three kinds of tea-green tea (GT) from Japan, Po-lei tea (PT) from China, and Rooibos tea (RT) from South Africa-on the induction of chromosome aberrations in cultured CHO cells and mice were studied. When CHO cells were exposed to each tea extract in the presence of rat liver microsomal enzymes (S9 mix) together with benzo`a:pyrene (B(a)P) or mitomycin C (MMC), a decrease in the frequency of chromosome aberrations was observed. PT and RT, but not GT, also suppressed the induction of chromosome aberrations by MMC in the absence of S9 mix. When cells were treated with tea extract after B(a)P or MMC treatment, RT suppressed the induction of chromosome aberrations in the presence and absence of S9 mix whereas GT and PT showed suppressing effects only in the presence of S9 mix. These data suggest that catechines, well-known *antimutagens* in tea samples, might account for the inhibitory effect in the case of GT and PT. Since RT contains few catechines, several unknown *antimutagenic* components could be responsible for its effect. The *antimutagenic* effects of tea extracts at concentration levels consumed by humans were examined in mice using micronucleus induction with B(a)P or MMC. When mice received oral gavage of 0.2% GT, 0.1% PT, and 0.1% RT at 1.0 ml/mouse 6 h before intraperitoneal injection of MMC, a decrease in the frequency of micronuclei was observed. The induction of micronuclei by B(a)P was suppressed by oral dosage of GT, PT and RT at 1.0 ml/mouse/day for 28 days. This was not due to a delay in the maturation of micronucleated reticulocytes. In conclusion, intake of tea might suppress the mutagenic activity of certain potent mutagens in human beings. Author-abstract.

TI Inhibition and induction of SOS responses in Escherichia coli by cobaltous chloride.

SO Mutat-Res. 1993 Apr. 286(2). P 173-80.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Mutagenesis induced by several genotoxic agents has been reported to be inhibited by cobaltous chloride. In order to study the effects of this metal in some SOS functions we evaluated mutagenesis, lysogenic induction and phage reactivation in Escherichia coli cells treated with CoCl₂. We detected that cobaltous chloride, when present in the plating medium, was able to block mutagenesis and lysogenic induction

promoted by UV irradiation. We also found that CoCl₂ blocked protein synthesis, so we propose that this effect can be responsible for the *antimutagenic* and antilyso-genic effects of this metal. On the other hand, if the cells were treated for a short period of time with CoCl₂, in the absence of Mg, we observed that cobaltous chloride per se was able to promote lysogenic induction as well as to enhance the phage reactivation induced by UV irradiation. We conclude that depending on experimental conditions, cobaltous chloride may act either as an inhibitor or as an inducer of the SOS functions.

JT CARCINOGENESIS.
PT JOURNAL-ARTICLE (ART).
AB Many human cancers that are widely prevalent today can be prevented through modifications in life-styles, of which diet appears to be an important agent. Several dietary constituents modulate the process of carcinogenesis and prevent genotoxicity. Many plant constituents including turmeric appear to be potent *antimutagens* and antioxidants. Therefore the modulatory effects of turmeric and curcumin on the levels of benzo`a:pyrene induced DNA adducts in the livers of rats were studied by the newly developed 32P-postlabelling assay method. Turmeric when fed at 0.1, 0.5 and 3% and the active principle of turmeric (curcumin) when fed at a level of 0.03% in the diet for 4 weeks significantly reduced the level of BP-DNA adducts including the major adduct dG-N2-BP, formed within 24 h in response to a single i.p. injection of benzo`a:pyrene. The significance of these effects in terms of the potential anticarcinogenic effects of turmeric is discussed. Further, these results strengthen the various other biological effects of turmeric which have direct relevance to anticarcinogenesis and chemoprevention. Author-abstract.

JT CARCINOGENESIS.
PT JOURNAL-ARTICLE (ART).
AB Chromium metal salts are considered to be human carcinogens, especially the salts of low solubility. Lead chromate, a highly

insoluble chromium metal salt, has been shown to be tumorigenic, genotoxic and clastogenic. In this study, the roles of particle-cell contact, particle dissolution and particle uptake in the clastogenic activity of lead chromate were investigated. Using Pb51CrO4 it was found that lead chromate particles (1.2 microns mean diameter, -28 mV surface charge) were slightly soluble in water; solubility increased 2-fold when particles were incubated in culture medium, but was not increased further by the addition of serum. The extracellular concentration of chromium increased 7-fold when lead chromate was incubated in the presence of Chinese hamster ovary (CHO) cells compared with culture medium alone. The intracellular concentration of ionic chromium increased in a dose-dependent manner following exposure of CHO cells to clastogenic doses of lead chromate reaching estimated levels as high as 1.2 mM per cell. Treatment of cells with lead chromate particles in the presence of a nontoxic dose of vitamin C blocked uptake of ionic chromium and eliminated the clastogenic activity of the particles. Transmission electron microscopy showed that lead chromate particles were internalized by CHO cells in phagocytic vacuoles in as little as 1 h; internalization was unaffected by co-treatment with vitamin C. It was demonstrated that particle-cell contact was required for lead chromate-induced clastogenesis. These data show that although phagocytic particle uptake occurs, particle-cell contact and extracellular dissolution are responsible for the clastogenic activity of lead chromate. These data also demonstrate that the genotoxicity of particulate hexavalent chromates can be blocked by vitamin C. Author-abstract.

JT PROSTAGLANDINS LEUKOTRIENES AND ESSENTIAL FATTY ACIDS.

PT JOURNAL-ARTICLE (ART).

AB Prostacyclin (PGI₂) prevented genetic damage to the bone marrow cells of mice induced by gamma-radiation, benzo(a)pyrene(BP) and cis-platinum(cis-DDP). Carba-PGI₂, an analogue of PGI₂, was also effective against cis-DDP-induced mutagenicity. In a time-course study it was observed that the geno-protective action of PGI₂, can last as long as 24 hr. 6-keto-PGF₁ alpha, a major metabolite of PGI₂ and c-AMP, a second messenger, were ineffective in bringing about this beneficial action. PGI₂ did not influence free radical generation induced by phorbol myristate acetate in human peripheral leukocytes. This suggests that the genoprotective action of PGI₂ is not mediated by its metabolite 6-keto-PGF₁ alpha and the second messenger cyclic-AMP and is not due to any action on free radical generation. This geno-protective action of PGI₂ would be futile if it interfered with the tumoricidal action of cis-DDP. It was observed that the cytotoxic action of cis-DDP against Meth-A tumor cells was not interfered with by PGI₂ and carba-PGI₂ both in vitro and in vivo. This description of the geno-protective action of PGI₂ is important in the development of new strategies in cancer chemotherapy since, it is likely that anticancer drugs, at least cis-DDP can be given along with PGI₂ to prevent genetic damage to normal cells without interfering with their tumoricidal action. SO Cancer-Res. 1993 Mar 1. 53(5). P 1149-55.

JT CANCER RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB The aldehyde reagent methoxyamine is able to interact with apurinic/apyrimidinic sites formed in vivo within cells and displays both an anti-cytotoxic and an *antimutagenic* activity on N-ethyl-N'-nitro-N-nitrosoguanidine-induced DNA damage in Chinese hamster ovary cells. To clarify the underlying mechanism we have examined the mutational spectra induced by N-ethyl-N'-nitro-N-nitrosoguanidine alone and in the presence of methoxyamine in the hypoxanthine-guanine phosphoribosyltransferase gene of Chinese hamster ovary cells. In both cases all mutations were base pair substitutions, and their distribution among various classes did not differ significantly. Almost 60% were transitions, predominantly GC to AT, and the remaining 40% were transversions, mainly at AT base pairs. The analysis of the proportion of the different types of mutations showed that in the presence of methoxyamine, GC to AT transitions decreased by a factor of 1.8, and AT to CG transversions were reduced by a factor of 13. These data indicate that in mammalian cells the fixation of ethylation damage into mutations occurs by both (a) direct mutagenesis likely driven by O6-ethylguanine adducts and to a minor extent by O4-ethylthymine and (b) apurinic/apyrimidinic site-mediated mutagenesis. These apurinic/apyrimidinic sites are formed during the processing of ethylation at critical sites and are likely to involve O6-ethylguanine and O2-ethylthymine adducts. Author-abstract.

SO Teratogenesis-Carcinog-Mutagen. 1992. 12(4). P 187-96.

JT TERATOGENESIS, CARCINOGENESIS, AND MUTAGENESIS.

PT JOURNAL-ARTICLE (ART).

AB The S9-mediated mutagenesis of IQ and MeIQ in Salmonella strain TA98 was modulated by introduction to the assay of tryptamine or tyramine. Both biogenic amines inhibited or enhanced the mutagenic response as a function of amine concentration, strain of rat used as the S9 source, and the IQ-type mutagen tested. Enhancement of IQ mutagenesis by tryptamine (10-80 microM) was observed in the presence of S9 preparations derived from Aroclor 1254-pretreated Fischer rats; the enhancing effect ceased at tryptamine concentrations > 160 microM. When Sprague-Dawley-S9 or Wistar-S9 were used for activation, the enhancement of IQ mutagenesis by tryptamine shifted to inhibition at tryptamine concentrations > 40 microM, with Sprague-Dawley-S9, and > 20 microM, with Wistar-S9. By contrast, MeIQ-mutagenesis was enhanced by tryptamine (10-160 microM), regardless of the rat strain used as S9 source. Tyramine was a weaker enhancer of MeIQ mutagenesis than was tryptamine and, unlike tryptamine, its inhibitory effects on IQ mutagenesis were observed only with Wistar-S9. Tryptamine (10-80 microM) inhibited cytochromes P450IA1 and P450IA2 activities, monitored by the O-deethylation of ethoxyresorufin and Glu-P-1 mutagenesis in TA98, respectively. These data suggest that the effects of biogenic amines on IQ and MeIQ bioactivation are complex. Furthermore, this study demonstrates that tryptamine and tyramine act both as enhancers (comutagens) and as inhibitors *(antimutagens)* of IQ and MeIQ mutagenesis, depending on the testing conditions. TI Desmutagenic activity of natural humic acids: inhibition of mitomycin C and maleic hydrazide mutagenicity.

SO Mutat-Res. 1993 Mar. 299(1). P 37-44.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Humic acids are natural components of organic matter widespread in the environment. In spite of the incomplete knowledge about their composition, increasing interest in humic acid activity is justified by their ubiquity. Four different humic acids have been tested in Chinese hamster ovary cells in vitro, both alone and in combination with two well-known mutagens (mitomycin C and maleic hydrazide). Data about sister-chromatid exchanges, mitotic and proliferation indices were collected. Our results, on the whole, indicate: (i) a slight mutagenicity and toxicity of tested humic acids, probably due to chlorination during sample preparation; (ii) a desmutagenic rather than *antimutagenic* activity of the tested humic acids.

TI Vitamin C-mediated minimisation of Rogor-induced genotoxicity.

SO Mutat-Res. 1993 Mar. 299(1). P 29-36.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB The genotoxic effect of Rogor (an organophosphorous pesticide) at concentrations used in agriculture was studied in terms of mitotic index in onion root-tip cells, chromosome abnormalities and meiotic index in mice and lastly, lethal mutation rate in *Drosophila*. It was observed that the pesticide could (i) cause mitotic as well as meiotic inhibition, (ii) increase the clastogenicity rate and (iii) induce lethal mutations. The modificatory role, if any, of L-ascorbic acid (vitamin C) was studied after administering the vitamin concurrently with the pesticide. It was observed that the cytogenetic toxicity of Rogor can be appreciably minimised by vitamin C. The possible mode of antigenotoxic action of vitamin C was discussed. Author-abstract.

TI Genotoxic evaluation of ammonium inactivated aflatoxin B1 in mice fed with contaminated corn.

SO Mutat-Res. 1993 Mar. 299(1). P 1-8.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Aflatoxin B1 (AFB1) is a major contaminant in different agricultural products including maize. In an attempt to reduce this problem and the hazards to human health, an AFB1 inactivating system with ammonia has been developed. In this work we evaluated the efficiency of the system in mice using micronucleus (MN) and sister chromatid exchange

(SCE) analysis. Four groups of animals were fed during 8 weeks with a special diet mainly composed of maize: (1) uncontaminated; (2) uncontaminated/inactivated; (3) contaminated/inactivated; and (4) contaminated. We evaluated MN at weekly intervals in peripheral blood, and in weeks 4 and 8 SCE frequencies were quantified in bone marrow cells. The results showed that animals fed with AFB1 contaminated/inactivated maize had a 45% lower level of induced cytogenetic damage than those animals fed with AFB1 contaminated, but not inactivated maize. A residual amount of AFB1 after the inactivating treatment and the reversion back to AFB1 in the organism may account for the remaining increased levels of SCE and MN. Author-abstract.

SO Cancer-Lett. 1993 Jan 15. 68(1). P 75-82.

JT CANCER LETTERS.

PT JOURNAL-ARTICLE (ART).

AB *Oldenlandia diffusa* (OD) and *Scutellaria barbata* (SB) have been used in traditional Chinese medicine for treating liver, lung and rectal tumors. We previously showed that they inhibited mutagenesis, DNA binding and metabolism of benzo(a)pyrene (BaP) and aflatoxin B1 (AFB1) bioactivated by Aroclor 1254-induced rat hepatic S9. The purpose of this study was to investigate the effects of OD and SB on the cytochrome P-450IA1-mediated mutagenicity of BaP in *Salmonella typhimurium* TA100 using beta-naphthoflavone (beta NF)-induced rat hepatic S9. We also determined the effects of OD and SB on

cytochrome P-450IA1-linked ethoxyresorufin O-deethylase (EROD) activity in beta NF-induced hepatic microsomes. In addition, we studied the effects of these two herbs on BaP metabolite binding to calf thymus DNA and using high performance liquid chromatography (HPLC) we investigated the effects of OD and SB on the metabolism of BaP by beta NF-induced S9. Our experimental results showed that OD and SB inhibited the mutagenicity of BaP in the presence of either non-induced or beta NF-induced S9. SB significantly inhibited BaP binding to DNA. These effects correlated with the inhibition of cytochrome P-450IA1-linked EROD activity in beta NF-induced microsomes and with an inhibition of beta NF-induced S9 mediated metabolism of ³H:BaP as determined by HPLC. These results suggest that OD and SB may possess *antimutagenic* activity by inhibiting P-450IA-mediated metabolism of BaP. Author-abstract.

TI Oxidants are a major contributor to aging.

SO Ann-N-Y-Acad-Sci. 1992 Nov 21. 663. P 85-96.

JT ANNALS OF THE NEW YORK ACADEMY OF SCIENCES.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-ACADEMIC (RAC).

AB Very high level oxidative damage to DNA occurs during normal metabolism. In each rat cell the steady-state level of this damage is estimated to be about 10(6) oxidative adducts, and about 10(5) new adducts are formed daily. This endogenous DNA damage appears to be a major contributor to aging and to the degenerative diseases associated with aging such as cancer. The oxidative damage rate in mammalian species with a high metabolic rate, short life span, and high age-specific cancer rate such as rats is much higher than the rate in humans, long-lived mammals with a lower metabolic rate and a lower age-specific cancer rate. It is argued that deficiency of micronutrients that protect against oxidative DNA damage is a major contributor to human cancer. Epidemiological studies, a large body of experimental evidence, and theoretical work on the mechanisms of carcinogenesis point to mitogenesis as a major contributor to cancer. Dividing cells compared to nondividing cells are at an enormously increased risk for mutations in part due to the conversion of DNA adducts to mutations. Mitogenesis also increases the probability of gene amplification and loss of 5-methylcytosine. Dietary interventions that lower mitogenesis, such as calorie restriction, decrease the incidence of cancer. Author-abstract. 103 Refs.

conditioned with hydrogen peroxide as measured by the cytokinesis-block micronucleus technique.

SO Mutat-Res. 1993 Feb. 301(2). P 135-41.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB We have made use of the cytokinesis-block micronucleus method to evaluate the adaptive response in human lymphocytes from two donors conditioned with low doses of hydrogen peroxide before irradiation with either 1.5 or 3.0 Gy of X-rays. A protective effect of pre-exposure to H₂O₂ against radiation damage detected as micronuclei in binucleate cells was evident in cells allowed to recover for different periods after X-ray exposure, though cells challenged with 3.0 Gy of X-rays showed the adaptive response at later fixation time than those exposed to the lower dose (1.5 Gy). We propose this protocol as an interesting alternative to the single fixation method to score chromosomal aberrations at metaphase for the study of the adaptive response. Author-abstract.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB The inactivation of 3-amino-1,4-dimethyl-5H-pyrido`4,3-b:indole (Trp-P-1) and 2-amino-6-methyldipyrido`1,2-a: 3',2'-d:imidazole (Glu-P-1) by binding of mutagenic pyrolysate to fractions of microorganisms (their desmutagenic and *bio-antimutagenic* activity) was investigated. All strains bound Trp-P-1 effectively, but Glu-P-1 to a lesser extent. The Gram-negative bacteria (GNB) could bind about 10-20 micrograms/mg of Trp-P-1 more than the Gram-positive bacteria (GPB), and about 50-60 micrograms/mg more than the yeasts. The cell wall skeletons of all strains tested had great binding ability, but in the cytoplasm of all strains tested it was lower. The peptidoglycan, outer membrane, and glucan isolate from the cell wall skeletons showed the highest binding ability to Trp-P-1. The cell wall skeletons of the tested strains greatly inhibited the mutagenicity induced by Trp-P-1, and to a lower extent that of 2-amino-3,8-dimethylimidazo`4,5-f:quinoxaline (MeIQx). Although the cultured broth and solution of cells extracted by phosphate buffer (pH 7.0) showed antimutagenicity against Trp-P-1, this activity was lower than the binding of Trp-P-1 to the cells. The cultured broth and freeze-dried cytoplasm of yeast cells showed bio-antimutagenicity towards Trp-P-1, but those of all bacteria tested did not. Author-abstract.

 SO Carcinogenesis. 1992 Dec. 13(12). P 2317-20.
 JT CARCINOGENESIS.
 PT JOURNAL-ARTICLE (ART).
 AB Extracts of human urine were shown to contain substances that strongly inhibited the liver S9-mediated mutagenicity of 2-amino-1-methyl-6-phenylimidazo`4,5-b:pyridine (PhIP) in Salmonella typhimurium TA98 strain in a liquid incubation assay. The inhibitory effect was unrelated to cytotoxicity and was similar with urine extracts from smokers and non-smokers. Under similar assay conditions, the mutagenicity of the related amino-imidazoazaarenes,

2-amino-3-methyl-imidazo`4,5-f:quinoline,
 2-amino-3,8-dimethylimidazo`4,5-f:-quinoline and
 2-amino-3,8-dimethylimidazo`4,5-f:quinoxaline was also found to be
 strongly inhibited by urine extracts. Decreased or enhanced
 mutagenicity was seen with 2-acetyl-aminofluorene and
 2-aminoanthracene depending on the type of assay, and the time of
 incubation in liquid medium. A weak inhibition of the mutagenicity
 of 2-nitrofluorene, a direct-acting mutagen, was observed only after
 a short incubation time. Mutagenicity of 4-nitroquinoline N-oxide
 was not altered by the presence of urine extracts at concentrations
 shown to be inhibitory for the mutagenicity of heterocyclic aromatic
 amines. Our data suggest that the inhibitory substances in urine act
 through their capacity to non covalently bind the parent heterocyclic
 and aromatic amines, thus affecting their availability in aqueous
 medium for diffusion into liver microsomes where metabolic activation
 takes place. Author-abstract.

TI Chlorophyllin is both a positive and negative modifier of
 mutagenicity.

SO Mutagenesis. 1992 Sep. 7(5). P 349-55.

JT MUTAGENESIS.

PT JOURNAL-ARTICLE (ART).

AB The mechanism responsible for the modification of mutagenicity by
 chlorophyllin has been investigated using mutagenic compounds with
 different mechanisms of action, including the monofunctional
 alkylating agents, N-methyl-N'-nitrosourea (MNU) and
 ethylmethanesulphonate (EMS); nitrosamines related to tobacco
 products, i.e. dimethyl-nitrosamine (DMN), N-nitrosornicotine
 (NNN) and 4-(N-methyl-N-nitrosoamino)-1-(3-pyridinyl)-2-butanone
 (NNK); the polycyclic aromatic hydrocarbon (PAH) benzo`a:pyrene
 (B`a:P) and two of its metabolites, i.e. (-)-7 beta,8
 alpha-dihydroxy-7,8-dihydrobenzo`a:pyrene (7,8-diol) and (+)-7 beta,8
 alpha-dihydroxy-9 alpha,10 alpha-oxy-7,8,9,10-
 tetrahydrobenzo`a:pyrene (BPDE); and a complex mutagenic mixture, an
 extract and subfractions of Swedish moist oral snuff (SMOS).
 Mutagenicity was monitored with the Ames Salmonella/microsome assays
 (STY) and hprt V79 point mutation assay (V79). The effects of
 chlorophyllin on the mutagenicity of the nitrosamines in the STY
 assays were found to be complex. In the presence of either NNN or
 NNK, low concentrations of chlorophyllin actually potentiated the
 mutagenicity > 2-fold. However, at higher, but still non-toxic
 concentrations, chlorophyllin decreased the mutagenicity of both
 compounds. The same type of dose-response relationship for
 chlorophyllin was indicated in the V79 assay system with DMN,
 although the effect was much weaker. The results with STY were

further confirmed by replacing chlorophyllin with another porphyrin compound, hemin. In contrast, biliverdin, a porphyrin structure without the central metal ion, was unable to potentiate the mutagenicity of NNK in STY.(ABSTRACT TRUNCATED AT 250 WORDS).

SO EXS. 1992. 62. P 227-34.
JT EXS.
PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).
AB A large number of studies have indicated that carotenoid pigments act
as anticarcinogenic agents in animals treated with either ultraviolet

light, ultraviolet light with chemicals, or with chemical carcinogens alone. Although pharmacological doses of carotenoids were used in the early experiments, more recent evidence indicates that relatively small doses can be effective. These studies have been complemented by investigations in bacteria and mammalian tissue, either in cell culture or in organ culture, where it has been demonstrated that various carotenoid pigments can prevent mutagenesis, genotoxic effects, or malignant transformation. It would appear that these effects are intrinsic to the carotenoid molecule, and not necessarily due to the metabolic conversion to retinoids. Partially based on these observations, it has been suggested that carotenoid pigments may function as chemopreventive agents for reducing the risk of cancer in humans. Numerous studies are underway to test this hypothesis. Author-abstract. 44 Refs.

AB The anticlastogenic effects of 13-cis-retinoic acid were studied in four human lymphoblastoid cell lines and in primary lymphocyte cultures derived from the peripheral blood of 11 study subjects. Cells were pre-incubated with 13-cis-retinoic acid in the concentration range of 10^{-8} - 10^{-5} mol/l for 24 h and the numbers of chromatid breaks per cell induced by bleomycin were determined. The presence of 13-cis-retinoic acid decreased the number of breaks per cell by 13.0 to 59.5% in lymphoblastoid cell lines and by 0 to 57.4% in primary lymphocyte cultures (in the concentration ranges of 10^{-8} - 10^{-6} mol/l and of 10^{-8} - 10^{-5} mol/l, respectively). Regression analysis showed that there was a statistically significant correlation between the presence of 13-cis-retinoic acid and protection against bleomycin-induced clastogenicity. These data give additional information to the knowledge of possible chemopreventive mechanisms of action of 13-cis-retinoic acid. Author-abstract.

TI Ellagic acid protects rat embryos in culture from the embryotoxic effects of N-methyl-N-nitrosourea.

SO Teratology. 1992 Aug. 46(2). P 109-15.

JT TERATOLOGY.

PT JOURNAL-ARTICLE (ART).

AB Ellagic acid is a naturally occurring plant phenol that has demonstrated anticarcinogenic and *antimutagenic* activity in several test systems. Given the common proposed etiopathogenic processes of mutagenesis, carcinogenesis, and teratogenesis induced by genotoxic chemicals, the present study was initiated to determine whether ellagic acid would protect rat embryos in culture from the teratogenic effects of N-methyl-N-nitrosourea (MNU). Ellagic acid alone (as used in these experiments; 50 microM in DMSO) was not embryotoxic. Ellagic acid (50 microM) significantly (P less than 0.01) prevented MNU (75 microM)-induced effects including mortality (absence of heart beat), abnormal formation of the cephalic neural tube derivatives, and delayed differentiation as assessed by a morphological scoring system. These embryoprotective effects were dose responsive. Sequential treatment of embryos with ellagic acid followed by MNU in fresh media also was embryoprotective with no diminution of effect. The site at which ellagic acid interrupts the critical teratogenic events induced by MNU is apparently within the embryo and/or placenta. This model of chemical embryoprotection may be useful in determining the role of cell death and/or mutation in the teratogenic mechanism of action of methylating agents.

JT NUTRITION AND CANCER.

PT JOURNAL-ARTICLE (ART).

AB Ellagic acid (EA), derived from fruit ellagitannins, is known to be *antimutagenic* and anticarcinogenic in various animal tumor models. In this study, EA at a dose of 4 g/kg diet inhibited multiplicity of tumors induced by 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK) in A/J mice by 54%. This inhibition was dose related between 0.06 and 4.0 g/kg diet. In contrast, two related compounds, esculin and esculetin, had no effect on lung tumorigenesis. The biodistribution of EA was studied as a function of dose and time after gavage of EA. The levels of EA in the lung were directly proportional to the dose of EA between 0.2 and 2.0 mmol. The maximum level of EA, corresponding to 21.3 nmol/g, was observed 30 minutes after gavage with 2.0 mmol of EA/kg body wt, which corresponds to only 70 ppm of the administered dose. The levels in liver tissues were 10-fold lower and reached a maximum 30 minutes after gavage. At this interval, the blood level of EA was 1 nmol/ml. The inclusion of EA in cyclodextrin doubles the level of EA in lung tissues. These results demonstrate that EA localizes preferentially in lung tissues and confirm that EA administered orally can inhibit lung

tumorigenesis. Author-abstract.

TI *Antimutagenic* and anticarcinogenic effects of carotenoids and dietary palm oil.

SO Nutr-Cancer. 1992. 17(3). P 287-95.

JT NUTRITION AND CANCER.

PT JOURNAL-ARTICLE (ART).

AB Four carotenoids, canthaxanthin, beta-carotene, 8H-apo-beta-carotenal, and 8'-apo-beta-carotene methylester were tested for their ability to suppress the mutagenicity of 1-methyl-3-nitro-1-nitrosoguanidine and benzo`a:pyrene (BP) in Salmonella typhimurium tester strain TA 100. The anticarcinogenic efficacy of the four carotenoids was further assessed in the BP-induced forestomach tumor model in female Swiss mice. The effect of dietary palm oil was also examined in BP-induced neoplasia in the female Haffkine Swiss mouse strain. Canthaxanthin, beta-carotene, 8'-apo-beta-carotenal, and 8'-apo-beta-carotene methylester showed a dose-dependent decrease in the mutagenicity compared with 1-methyl-3-nitro-1-nitrosoguanidine and BP in strain TA 100. In the BP-induced forestomach tumor model, all four carotenoids showed a similar significant anticarcinogenic effect. Dietary administration of palm oil showed a dose-dependent antitumor activity in the animals. Our results show that the intrinsic *antimutagenic* and anticarcinogenic properties of the carotenoids are not significantly influenced by their conversion to vitamin A. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB *Antimutagenic* activities of hexane extracts obtained from the fruit extract (UE) and the Kernels (KE) of P. mume were examined. These extracts showed inhibitory activities to known mutagens, 2-(2-furyl)-3-(5-nitro-2-furyl)acrylamide, benzo`alpha:pyrene and aflatoxin B1 in the Ames assay using Salmonella typhimurium TA100 and TA98 strains. The UE and KE fractions were then separated by silicic acid column chromatography with a stepwise elution method using ether-hexane. The location of the active substances in the fractions was also determined by thin-layer chromatography. Consequently, it was found that the effective substances for the desmutagenicity were fatty acids, and identified by gas liquid chromatography, mainly as

oleic acid, linoleic acid and linolenic acid in UE, and mainly as oleic acid and linoleic acid in KE, respectively. Author-abstract.

JT ENVIRONMENTAL AND MOLECULAR MUTAGENESIS.

PT JOURNAL-ARTICLE (ART).

AB Two photoproducts, derived from UV-irradiation of the amino acid L-tryptophan and with high Ah (TCDD) receptor binding affinity, were tested for genotoxic and *antimutagenic* effects. The two indolo`3,2-b:carbazole derivatives, with the molecular weights of 284 and 312, respectively, were tested in *Saccharomyces cerevisiae* strain D7 for mitotic gene conversion and reverse mutation and in strain RS112 for sister chromatid conversion and gene conversion. No significant ($P > 0.05$) genotoxic effects were found in strain D7, while strain RS112 showed a small but significant increase in the frequency of sister chromatid conversions. In Chinese hamster ovary (CHO) cells the two compounds induced a statistically significant but less than twofold increase in the frequency of sister chromatid exchanges (SCE). No mutations were detected when the compounds were tested in *Salmonella typhimurium* strains TA98 and TA100. However, both 284 and 312 acted as *antimutagens* on strain TA100 + S9 in the presence of benzo(a)pyrene. The decrease in mutagenicity by the most potent compound 284 was 20 revertants/nmol. This effect could be explained by an inhibitory effect on the cytochrome P450-dependent ethoxyresorufin O-deethylase (EROD) activity as seen in rat hepatocytes. The two compounds were also tested with hamster cells expressing rat cytochrome P-450IA1. The results support the conclusion that this cytochrome P-450 isozyme is inhibited by the tryptophan photoproducts. Similar results were also seen with two other high affinity Ah receptor ligands the quinazolinocarboline alkaloids rutaecarpine and dehydrorutaecarpine. Author-abstract.

JT CHEMICO-BIOLOGICAL INTERACTIONS.

PT JOURNAL-ARTICLE (ART).

AB Propolis, a honey bee hive product, is thought to exhibit a broad spectrum of activities including antibiotic, antiviral, anti-inflammatory and tumor growth inhibition; some of the observed biological activities may be due to caffeic acid (cinnamic acid) esters that are present in propolis. In the present study we synthesized three caffeic acid esters, namely methyl caffeate (MC), phenylethyl caffeate (PEC) and phenylethyl dimethylcaffeate (PEDMC) and tested them against the 3,2'-dimethyl-4-aminobiphenyl, (DMAB, a colon and mammary carcinogen)-induced mutagenicity in *Salmonella typhimurium* strains TA 98 and TA 100. Also, the effect of these agents on the growth of human colon adenocarcinoma, HT-29 cells and

activities of ornithine decarboxylase (ODC) and protein tyrosine kinase (PTK) was studied. Mutagenicity was induced in *Salmonella typhimurium* strains TA 98 and TA 100 plus S9 activation using 5 and 10 micrograms DMAB and *antimutagenic* activities of 0-150 microM MC, 0-60 microM PEC and 0-80 microM PEDMC were determined. The results indicate that MC, PEC and PEDMC were not mutagenic in the *Salmonella* tester system. DMAB-induced mutagenicity was significantly inhibited with 150 microM MC, 40-60 microM PEC and 40-80 microM PEDMC in both tester systems. Treatment of HT-29 colon adenocarcinoma cells with > 150 microM MC, 30 microM PEC and 20 microM PEDMC significantly inhibited the cell growth and syntheses of RNA, DNA and protein. ODC and PTK activities were also inhibited in HT-29 cells treated with different concentrations of MC, PEC and PEDMC. These results demonstrate that caffeic acid esters which are present in Propolis possess chemopreventive properties when tested in short-term assay systems. Author-abstract.

JT BASIC LIFE SCIENCES.

PT JOURNAL-ARTICLE (ART).

AB Naturally occurring plant phenols with *antimutagenic* and anticarcinogenic activities were tested for their abilities to inhibit the biochemical and biological effects of the potent tumor promoter 12-O-tetradecanoyl-phorbol-13-acetate (TPA) in mouse epidermis in vivo. When applied topically to mouse skin, tannic acid (TA), ellagic acid, and several gallic acid derivatives all inhibit TPA-induced ornithine decarboxylase activity, hydroperoxide production, and DNA synthesis, three biochemical markers of skin tumor promotion. Moreover, in the two-step initiation-promotion protocol, the same phenolic compounds also inhibit the incidence and yield of skin tumors promoted by TPA. TA is the most effective of these treatments. Since they are already known to inhibit tumor initiation, the plant phenols protecting against skin tumor promotion by TPA may be universal inhibitors of multistage carcinogenesis. TA and other polyphenols, therefore, might be valuable in cancer therapy and/or prevention. Author-abstract.

TI (-)-Epigallocatechin-3-gallate in *Camellia sinensis* leaves from Himalayan region of Sikkim: inhibitory effects against biochemical events and tumor initiation in Sencar mouse skin.

SO Nutr-Cancer. 1992. 18(1). P 73-83.

JT NUTRITION AND CANCER.

PT JOURNAL-ARTICLE (ART).

AB Recently, we and others showed that the components of green tea may be useful cancer chemopreventive agents. It has been suggested that (-)-epigallocatechin-3-gallate (EGCG), the major constituent in green tea, may possess antitumor-promoting and/or anticarcinogenic effects in rodent tumor bioassay systems. During the chemical analysis of various green tea products, we found a traditionally preserved preparation of green tea used by tribes in the Himalayan region of Sikkim, India that was rich in EGCG. EGCG was isolated from this tea product, and its inhibitory effects were evaluated against the binding of topically applied ³H-labeled polycyclic aromatic hydrocarbons (PAHs) to epidermal DNA and 12-O-tetradecanoylphorbol-13-acetate (TPA) caused induction of epidermal ornithine decarboxylase (ODC) activity in Sencar mice, the short-term markers of tumor initiation and tumor promotion, respectively. Preapplication of EGCG resulted in significant inhibition (p less than 0.05) in the binding of ³H:PAH to epidermal DNA. Similarly, the topical application of EGCG resulted in

significant inhibition (p less than 0.005) in TPA-caused induction of epidermal ODC activity. In further studies, we assessed the anti-skin tumor-initiating effect of EGCG in Sencar mice in an initiation-promotion protocol. The application of EGCG before challenge with 7,12-dimethylbenz^a:anthracene as tumor initiator resulted in significant reduction both in percentage of mice with tumors and number of tumors per mouse compared with a non-EGCG-pretreated group of animals. The results of the present study suggest that the green tea preparation from Sikkim may be a good source for the isolation of EGCG and that this compound may have significant potential as a cancer chemopreventive agent.

SO Mutat-Res. 1992 Nov 16. 270(2). P 87-95.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Four naturally occurring compounds, indole-3-carbinol (I3C), apigenin (Api), ellagic acid (EA) and tannic acid (TA), were tested for their inhibitory effects against 1-nitropyrene- (1-NP) or 1,6-dinitropyrene (1,6-DNP)-induced genotoxicity in Salmonella tester strains and Chinese hamster ovary (CHO) cells. Api and TA strongly inhibited the bacterial mutagenesis induced by nitropyrenes, while I3C and EA had little or no effect. For example, in TA98, 0.2 μ mole Api resulted in 48% and 56% inhibition of the mutagenicity induced by 4 nmole 1-NP and 0.035 nmole 1,6-DNP, respectively. With an equal dose, TA caused 46% and 50% reduction of the mutagenicity induced by 1-NP and 1,6-DNP, respectively. As expected, a good correlation was observed between the antimutagenicity of nitropyrenes and their inhibitory effect on nitroreductase activity. This indicated that one of the possible *antimutagenic* mechanisms of Api or TA was to inactivate the metabolism of nitropyrenes. Two biological end-points, cytotoxicity and sister-chromatid exchange (SCEs), were used to screen the antigenotoxic effects of these compounds in CHO cells. At the sub-cytotoxic dose, I3C, Api and TA all protected against the cytotoxicity induced by 1-NP and 1,6-DNP, but only TA and Api gave a significant reduction of the frequency of SCEs. Moreover, this reduction was found to be highly dose-dependent. Author-abstract.

TI Synergistic effect between tannic acid and X-rays detected by the Tradescantia-micronucleus assay.

SO Mutat-Res. 1992 Nov 1. 270(1). P 31-7.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Tannic acid (TA), a complex mixture of polyphenolics, exhibited synergism with 4-nitroquinoline 1-oxide (4-NQO), methyl methanesulfonate (MMS) and cis-platinum (cis-DDP) in a recent study on w/w+ somatic mutation in the eye pigment of *Drosophila*, although several studies indicated that tannic acid is an *antimutagen* in cultured mammalian cells. The goal of this study was to determine the genotoxicity of tannic acid alone and its possible synergistic effect with X-rays using the Tradescantia-micronucleus (Trad-MCN) bioassay. Plant cuttings were irradiated with 35 R of X-rays (80 kV, 5 mA) and followed by a series of increasing dosages (0.1, 0.5, 0.75, 1.0, 1.25, 1.50 mM) of TA treatment (24 h) and in some cases TA treatment was followed by X-irradiation. Inflorescences were fixed after a 24-h recovery period and slides were prepared for scoring MCN frequencies. Four series of experiments were conducted and the results of Trad-MCN tests on X-rays alone yielded an average of 47.5 MCN/100 tetrads (SE = 6.08), and 1.0 mM TA alone yielded an average of 8.95 MCN/100 tetrads (SE = 0.1), while the combined treatments (35 R X-rays plus 1.0 mM TA) yielded an average of 126.95 MCM/100 tetrads (SE = 13.69). The MCN frequency of the negative control was around 4.6 MCN/100 tetrads (SE = 0.75). This kind of synergism was exhibited through all the increasing dosages around 1.0 mM or higher. The synergistic effect of these two agents remained at the same level when TA was followed by X-irradiation. When a 12-h repairing period was allowed after X-irradiation in the combined treatment, the MCN frequency was similar to that of the X-ray treatment alone. The synergistic effect in the cases where the TA exposure was given immediately after X-irradiation could be attributed to the inhibitory action of TA on the DNA repair process. Author-abstract.

TI Effects of sodium selenite and caffeine on mutagenesis induced by N-methyl-N-nitrosourea, N-methyl-N'-nitro-N-nitrosoguanidine and aflatoxin B1 in *S. typhimurium*.

SO Mutat-Res. 1992 Oct. 269(2). P 307-17.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Pre-treatment, co-treatment, and post-treatment procedures were comparatively used in order to assess the modulation of mutagenicity in *S. typhimurium* his- strains. Pre-treatment of bacteria with sodium selenite had no effect on sodium azide mutagenicity. Irrespective of the procedure used neither selenite nor caffeine had

any influence on the S9-mediated mutagenicity of aflatoxin B1. In contrast, the mutagenicity of N-methyl-N-nitrosourea (MNU) and N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) was variably affected, depending on the sequence of exposures of target bacterial cells to mutagens and modulators. In particular, pre-treatment of bacteria with either selenite or caffeine or their combination generally resulted in a potentiation of MNU and MNNG mutagenicity. However, co-incubation of these alkylating agents and test modulators with bacterial cells yielded an evident inhibition of mutagenicity, the methylxanthine being more effective in this case. Caffeine exhibited an *antimutagenic* effect towards MNU also when assayed in a post-treatment procedure. Thus, in dependence on the test conditions, selenite and caffeine could act in the same mutagenicity assay as co-mutagens, *antimutagens* or agents without effect on mutagenesis. These opposite trends reflect the complexity of the mechanisms of action of both mutagens and modulators tested, and underscore the variable outcome of their interactions, also depending on topological and chronological factors. The data reported emphasize the need for a multiple methodological approach in studies investigating the modulation of mutagenicity. Author-abstract.

gamma-ray induction of somatic and germ cell chromosome aberrations in the mouse.

SO Mutat-Res. 1992 Oct. 269(2). P 251-8.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB The polyvitamin product 'Pharmavit' (Pv), comprising vitamins A, D2, B1, B2, B6, C, E, nicotinamide, and calcium pantothenate, was tested for anticlastogenic properties against gamma-rays in mice. Pretreatment with Pv consisted of daily administration by gavage for 30 days at dose levels corresponding to clinical recommendations for an adult human, as recalculated in terms of mg/kg. Findings indicated a reduction of chromosome aberrations in bone marrow cells from mice exposed to 3.0 Gy ¹³⁷Cs gamma-rays; the reduction concerned predominantly fragments of the chromatid type. Furthermore, a reduction factor of 1.6 was obtained for the frequency of reciprocal translocations induced by spermatogonial irradiation in mice exposed to 4.0 Gy gamma-rays. Pretreatment with vitamin C alone, at the dose present in Pv, proved nearly ineffective in protecting from chromosome aberrations in bone marrow cells. Pharmavit is believed to be a promising agent for application to human populations exposed to the carcinogenic and genetic hazards of ionizing radiation. Author-abstract.

TI Mechanism of antimutagenicity of wheat sprout extracts.

SO Mutat-Res. 1992 Oct. 269(2). P 201-15.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB In this paper we have demonstrated that wheat sprout extract, which has been shown to be *antimutagenic* towards benzo`a:pyrene (BP), reduced formation of BP metabolites by hepatic microsomes of either benzo`a:pyrene- or phenobarbital-treated rats as analyzed in high-pressure liquid chromatography (HPLC). Comparing the time dependence of profiles and values of BP metabolites, formed in experiments in which the same dose of wheat sprout extract was added to the incubation medium, it has been observed that the later this extract was added the higher the percent of BP that was metabolized. In a bacterial test (cytochrome P450 induction assay) high inhibition of mutagenic activity of cyclophosphamide and ethidium bromide, in the presence of wheat sprout extract, reflected decreased levels of cytochromes P4502B1 and P4501A1 respectively. Decreased levels of both cytochromes P4501A1 and P4502B1 were also observed in either wheat sprout extract- or wheat sprout extract plus benzo`a:pyrene-treated rats. In all of these studies it has been observed that wheat sprout extract displays much more affinity for cytochrome P4501A1 than for the P4502B1 form. On the other hand the wheat sprout extract had higher affinity for carcinogen binding

protein (4S protein) than for the aryl hydrocarbon receptor. The strong inhibition of BP mutagenicity and BP metabolism with non-chlorophyllic wheat sprout extract suggests that chlorophyll is not the main compound responsible for the *antimutagenic* activity of wheat sprout extract. The similar chromatographic behavior of both the main inhibitory fraction, obtained from wheat sprout extract, and two pure glycosides of apigenin--shaftoside, purified from wheat sprout extract and synthetic swertisine--suggests that *antimutagenic* compound(s) contained in the wheat sprout extract belong(s) to this family of flavonoids. TI Natural antioxidants as inhibitors of oxygen species induced mutagenicity.

SO Mutat-Res. 1992 Oct. 269(2). P 193-200.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB A ternary antioxidant vitamin mix consisting of ascorbic acid, alpha-tocopherol and lecithin as well as a rosemary extract with carnosic acid and carnosol as the two major active ingredients were shown to exhibit strong *antimutagenic* effects in Ames tester strain TA102. This strain has been shown to be highly sensitive to reactive oxygen species. Mutagenicity was induced by the generation of oxygen radicals by tert-butyl-hydroperoxide (tBOOH) or hydrogen peroxide (H2O2); therefore, the *antimutagenic* property of the above substances was attributed to their antioxidant properties. In the case of the vitamin mix, ascorbic acid was held responsible for this inhibitory property, whereas for the rosemary extract carnosic acid was identified as the *antimutagenic* agent. Since oxygen radicals are known to be involved in the multiprocess of carcinogenicity, it is concluded that these antioxidants might exhibit anticarcinogenic properties. Author-abstract.

TI Inhibitory effect of carbohydrates on the formation of mutagens in fried beef patties.

SO Food-Chem-Toxicol. 1992 Aug. 30(8). P 681-8.

JT FOOD AND CHEMICAL TOXICOLOGY.

PT JOURNAL-ARTICLE (ART).

AB Beef patties were prepared by mixing minced meat with water and either glucose (1, 2 or 4%), lactose (1, 2 or 4%) or powdered milk (2, 4 or 8%) before frying. In another experiment, minced meat was

mixed with starch from golden bread crumbs (3%) or potatoes (4%), with and without glucose (1, 2 or 4%). The patties (100 g) were fried for 3 min at 150 or 180 degrees C in a double-sided fryer. The mutagenic activity in the crust was determined using the Ames test. With the addition of glucose or lactose (1-4%), the mutagenic activity was inhibited by 34-76%. A similar inhibition of the mutagenic activity was obtained with powdered milk. However, starch from golden bread crumbs or potatoes caused only a slight (not significant) decrease in mutagenic activity whereas adding both starch and glucose to the beef patties inhibited mutagenic activity by up to 54%. TI Beta-carotene as a modulator of chromosomal aberrations induced in mouse bone marrow cells.

SO Environ-Mol-Mutagen. 1992. 20(3). P 206-10.

JT ENVIRONMENTAL AND MOLECULAR MUTAGENESIS.

PT JOURNAL-ARTICLE (ART).

AB The inhibitory effects of beta-carotene on cyclophosphamide (CPA)-induced chromosomal aberrations in mouse bone marrow cells were investigated. Male Balb C mice, 8-10 weeks old, were treated with beta-carotene (0.5, 1.0, 2.0, 5.0, 10, 25, 50, 100, and 200 mg/kg) or with corn oil (0.05 ml/10 g b.w.) by gavage for 5 consecutive days. Four hours after the last treatment with or without beta-carotene, the animals were intraperitoneally injected with CPA and killed 24 hr later for cytological preparations and analysis. The results obtained show that beta-carotene provides significant protection against the clastogenicity of CPA. The maximum reduction in the frequency of aberrant metaphases (26.9%) and in total number of chromosomal aberrations were observed when beta-carotene was used at 50 mg/kg. Nevertheless, no direct dose-response relationship was detected, suggesting that beta-carotene might act through different mechanisms at different doses. The results obtained in animals studies have served as part of the basis for the human intervention studies now underway to determine if beta-carotene does indeed function as a chemopreventive agent in human nutrition. JT ENVIRONMENTAL AND MOLECULAR MUTAGENESIS.

PT JOURNAL-ARTICLE (ART).

AB Sodium/copper chlorophyllin (CHL) is a water-soluble derivative of chlorophyll that exhibits *antimutagenic* activity in several short-term genotoxicity assays and inhibits carcinogen-DNA binding in vivo. The effect of CHL pretreatment on the excretion of mutagens in the urine and feces of male Sprague-Dawley rats has been studied using the Salmonella mutagenicity assay. Animals were given 1 percent CHL in the drinking water for 2 days before administering a single dose of 2-amino-3-methylimidazo-`4,5-f:quinoline (IQ) by oral gavage. Rats pretreated with CHL had higher levels of mutagens in the urine and feces compared with animals given IQ alone; 48 hr after IQ administration, the total mutagenic dose excreted was < 4% in controls vs. 18% in rats given CHL. Mutagenicity required the presence of an activation system, was unaffected by treatment with beta-glucuronidase or arylsulfatase, and in both the urine and feces was accounted for by increased elimination of unmetabolized parent compound. The results support the view that CHL may operate in vivo as a "desmutagen" or interceptor molecule, interacting with IQ in the gut and tissues, and reducing carcinogen bioavailability.

SO Carcinogenesis. 1992 Sep. 13(9). P 1643-50.

JT CARCINOGENESIS.

PT JOURNAL-ARTICLE (ART).

AB The influence of various dietary constituents--phenethylisothiocyanate (PEITC), oleic acid (OA), triolein (TO), and vitamin A (ROL)--on the genotoxic activity of nitrosamines (NDMA, NDELA, NPYR) was investigated. For this purpose differential DNA repair assays with Escherichia coli K-12 strains were performed in vitro and in vivo with mice. Under in vitro conditions (liquid holding), all compounds reduced nitrosamine induced DNA-damage in the indicator bacteria in the dose range 1-10 micrograms/ml, the ranking order of efficiency being PEITC greater than OA greater than ROL greater than or equal to TO. In animal-mediated assays, acute oral treatment with PEITC (17-150 mg/kg), 2 h before nitrosamine administration, resulted in a marked decrease of nitrosamine genotoxicity in liver, kidneys, lungs and in the blood. Also in other organs (spleen, testes) an increase in differential survival (which serves as a measure for repairable DNA damage) occurred. With ROL only a comparatively moderate antigenotoxic effect was obtained at a high dose level (250 mg/kg)

under identical experimental conditions. OA (2000 mg/kg) and TO (16,000 mg/kg) were completely inactive. Upon repeated treatment (consecutive oral administration of the putative antigenotoxins over 4 days, a final treatment 24 h before nitrosamine administration) PEITC (150 mg/kg/day), ROL (80 mg/kg/day) and OA (2000 mg/kg/day) had no influence on the genotoxic effects of the nitrosamines. Repeated treatment with TO (4000-16,000 mg/kg/day) resulted in a moderate dose-dependent reduction of NDMA-induced DNA-damage in the indicator bacteria, whereas in combination with NPYR only a marginal effect was observed. Biochemical experiments indicated that the antigenotoxic effects of PEITC seen under in vivo conditions were due to inhibition of alpha-hydroxylation of the nitrosamines, whereas ROL and TO appeared not to interfere strongly with this metabolic activation step. Our results indicate that in vitro assays do only partly reflect the antigenotoxic properties of the different food constituents in vivo and that animal-mediated DNA repair assays with E. coli strains are an appropriate approach to study the effects of modifiers of nitrosamine genotoxicity in the living animal. JT CANCER LETTERS.

PT JOURNAL-ARTICLE (ART).

AB Smokers expose themselves to potent carcinogens daily. One of them is the nicotine-derived nitrosamine 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK). Since estimates are that humans consume 1 g of phenolic compounds/day, we investigated the inhibitory effects of five structurally related polyphenolic compounds on the mutagenicity of NNK in Salmonella typhimurium TA1535. NNK at a concentration of 80 mM was activated by hamster liver microsomes. The *antimutagenic* efficacies were dose-related between the non-toxic concentrations of 0.1 and 0.5 mmol/dish in the following order: esculetin > ellagic acid > (+)-catechin > propyl gallate > (-)-esculin. At the highest non-toxic dose tested (0.5 mmol/dish), these polyphenolics inhibited mutagenesis in TA1535 by 77%, 67%, 62%, 59% and 53%, respectively. The results of this study demonstrated that polyphenolic compounds may inhibit the activation of NNK. Author-abstract.

 AB Micronucleus induction in male F344 rat peripheral blood by potassium

bromate (KBrO₃), a rat renal carcinogen, and its inhibition by several antioxidants were studied using the acridine orange supravital staining method. The frequency of micronucleated reticulocytes (MNRETs) peaked 32 h after a single i.p. treatment of rats with KBrO₃ at a dose of 60 mg/kg. Co-treatment with glutathione (GSH) or cysteine (Cys) i.p. at doses of 800 mg/kg and 400 mg/kg, respectively, 30 min before and 30 min after the KBrO₃ treatment significantly inhibited the micronucleus induction by KBrO₃. Daily i.g. administration of vitamin C for 5 days at a dose of 200 mg/kg/day was also effective in protecting against micronucleus induction by KBrO₃ given on the 4th day. However, co-treatment with superoxide dismutase in liposome-encapsulated form by i.p. injection at a dose of 18,000 U/kg 30 min before and 30 min after the KBrO₃ application exerted no effect. The results indicate that antioxidants, especially sulfhydryl compounds, have protective potential against the clastogenicity of KBrO₃, also suggesting that active oxygen species may play an important role in its clastogenicity. PT JOURNAL-ARTICLE (ART).

AB Low levels of mutagenic activities were detected in only 5-25% of the feces of people on a normal mixed-western diet, when feces were extracted by solvents and extracts were analyzed for mutagenicity with Ames' standard Salmonella/microsome assay. Since mutagens are known to be present in this type of diet and may be synthesized endogenously by bacteria in the large bowel, the question is if *antimutagenic* compounds mask the presence of genotoxic substances. We therefore tested the inhibition of known mutagens--benzo(a)-pyrene and sodium azide--by acetone/ethyl-acetate extracts of lyophilized feces in model experiments. These extracts completely suppressed the mutagenicity of benzo(a)pyrene and reduced the mutagenicity of sodium azide by about 60%, but were non-cytotoxic. Using gel filtration over Sephadex LH-20 and subsequent silica gel column chromatography we found that the inhibitors were polar organic compounds with molecular weights about 500 or more. The inhibitory effect could not be changed by esterification or saponification methods but was completely abolished by alkaline potassium permanganate oxidation. We therefore conclude that the *antimutagenic* activities might be identical with bile pigments. Author-abstract.

TI Inhibition by germanium oxide of the mutagenicity of cadmium chloride in various genotoxicity assays.

SO Food-Chem-Toxicol. 1992 Jun. 30(6). P 521-4.

JT FOOD AND CHEMICAL TOXICOLOGY.

PT JOURNAL-ARTICLE (ART).

AB The effects of germanium oxide on the genotoxicity of cadmium chloride were investigated. The incorporation of ³H:thymidine into testicular DNA was inhibited in mice injected ip with 1.35, 1.80 or 2.70 mg cadmium chloride/kg body weight. Germanium oxide (0.05 or 0.1 mg/kg body weight, sc) alone did not affect ³H:thymidine incorporation into testicular DNA but 0.05 mg germanium oxide/kg antagonized the inhibitory effect of 1.35 mg cadmium chloride/kg. However, combinations of the other doses of the two compounds did not show statistically significant antagonistic effects. Cadmium chloride significantly increased the frequencies of micronucleus formation in polychromatic erythrocytes, and of chromosome aberrations in the bone marrow of mice treated with 0.7, 1.4 or 2.7 mg/kg body weight, in a dose-related manner. These effects were inhibited by germanium oxide at doses of 0.1 or 0.5 mg/kg body weight, although germanium oxide alone did not affect micronucleus formation or the chromosome aberration rate. Cadmium chloride produced a dose-related increase in the frequency of sister chromatid exchanges in cultured human lymphocytes at concentrations of 5, 10 or 50 μmol. This effect was also inhibited by germanium oxide (0.05 or 0.1 μmol), although germanium oxide alone had no effect. There was a dose-related increase in the frequency of sperms with abnormal head morphologies from mice treated with 0.6, 1.1 or 2.2 mg cadmium chloride/kg body weight and this too was antagonized by the injection of germanium oxide (0.1 or 0.5 mg/kg body weight). Germanium oxide alone did not affect the frequency of sperm-head abnormalities. Author-abstract.

TI Breakage and binding of DNA by reaction products of hypochlorous acid with aniline, 1-naphthylamine, or 1-naphthol.

SO Toxicol-Appl-Pharmacol. 1992 Jul. 115(1). P 107-15.

JT TOXICOLOGY AND APPLIED PHARMACOLOGY.

PT JOURNAL-ARTICLE (ART).

AB Hypochlorous acid (HOCl) is a chemically reactive oxidant and a potent microbicidal agent that is synthesized in phagosomes of inflammatory neutrophils and released into extracellular spaces. Besides reducing pathogenicity by reacting with phagocytized infectious agents, HOCl may damage tissues and yield toxic products upon reaction with various other molecules, including xenobiotics. As model xenobiotics, the substituted aryl compounds aniline, 1-naphthylamine, and 1-naphthol (1-NOH) were investigated herein for their potential to react with HOCl and the transformed into genotoxic products. The compounds were first exposed to HOCl (25-150 microM) in phosphate buffer and afterward used to treat human fibroblasts or purified DNA. DNA single-strand breaks in cells and the binding of HOCl-reacted 1-¹⁴C:NOH to purified DNA were assessed by DNA alkaline elution and scintillation spectrometry, respectively. It was found that neither HOCl nor compounds alone could break cellular DNA. But HOCl-reacted compounds produced up to 400 rad equivalents of DNA breaks. HOCl reaction products of aniline and the model bicyclic aryl compounds differed in their DNA-breaking characteristics. HOCl-reacted 1-¹⁴C:NOH was stable and bound to DNA at up to 124 pmol/mg DNA. Sodium thiosulfate, glutathione, and taurine inhibited the transformation reactions; but only the former two blocked binding of HOCl-reacted 1-NOH to DNA. Ultraviolet spectra showed that HOCl reacted rapidly (less than 1 min) and equally well with 1-NOH at pH 7.2 or at an intraphagosomal pH of 5.0. Reaction concentrations of HOCl in this study were 2- to 11-fold lower than levels generated in vitro by stimulated neutrophils. These results show that certain aryl compounds can react readily with approximated physiological levels of HOCl (-OCl) to form relatively long-lived products that bind DNA and are genotoxic to human cells. TI Spontaneous mutagenesis: experimental, genetic and other factors.

SO Mutat-Res. 1992 Aug. 277(2). P 139-62.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-ACADEMIC (RAC).

AB Spontaneous mutations are "the net result of all that can go wrong with DNA during the life cycle of an organism" (Glickman et al., 1986). Thus, the types and amounts of spontaneous mutations produced are the resultant of all the cellular processes that are mutagenic and those that are *antimutagenic.* It is not widely appreciated that the types and frequencies of spontaneous mutations change markedly with subtle changes in experimental conditions. All types of mutations are produced spontaneously, i.e., base substitutions, frameshifts, insertions and deletions. However, very few papers have appeared that are devoted exclusively to the study of the mechanisms of spontaneous mutagenesis, and of the subtle experimental factors that affect the types and frequencies of spontaneous mutations. This is unfortunate because spontaneous mutagenesis appears to play a major role in evolution, aging, and carcinogenesis. This review emphasizes subtle experimental variables that markedly affect the results of a spontaneous mutation experiment. A thorough understanding of these variables eliminates the need for a theory of "directed" mutagenesis. The intrinsic instability of DNA, and the types of normal metabolic lesions that are produced in DNA that lead to mutations via errors made in replication, repair, and recombination are reviewed, as is the genetic control of spontaneous mutagenesis. As with spontaneous mutagenesis, spontaneous carcinogenesis can also be considered to be the net result of all that can go wrong with DNA during the life of an organism. Author-abstract. 167 Refs.

TI Modulation of the mutagenicity of three dinitropyrene isomers in vitro by rat-liver S9, cytosolic, and microsomal fractions following chronic ethanol ingestion.

SO Mutat-Res. 1992 Jun 16. 279(4). P 289-98.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB The effects of chronic ethanol feeding of rats on the ability of liver fractions to modulate the bacterial mutagenicity of three dinitropyrene isomers (1,3-, 1,6- and 1,8-DNP), which require bacterial enzymes but not an exogenous enzyme source for activation, were studied. The mutagenicity of the DNP isomers toward *S. typhimurium* TA98 and TA100 was attenuated in the presence of post-mitochondrial supernatants (S9) from both ethanol-fed and pair-fed rats albeit, that from the ethanol-fed group was more efficient in lowering the mutagenicity. The cytosolic fraction from ethanol-fed rats enhanced the mutagenicity of all of the DNP isomers in TA100. The most notable enhancement was with 1,3-DNP in which a more than 4-fold enhancement was obtained. Cytosol from pair-fed rats enhanced only the mutagenicity of 1,3-DNP, this by 2.9-fold. Cytosolic NADPH-nitroreductase activity from ethanol-treated rats toward 1,6-, 1,8- and 1,3-DNP was increased 2.8-, 1.7- and 1.3-fold, respectively over pair-fed controls. Cytosolic NADH-nitroreductase from ethanol-fed rats was increased with 1,3-DNP (1.7-fold) and 1,8-DNP (1.4-fold) as substrates, but not with 1,6-DNP. Microsomes decreased the mutagenicity of DNP similarly to S9, i.e., fractions from ethanol-fed rats were more efficient than those of pair-fed rats in deactivating all the DNP isomers. Per mg of protein, detoxification of DNP by S9 was more efficient than with microsomes, thus both cytosolic and microsomal enzymes are required for maximal

detoxification. In summary, ethanol feeding modulates both the augmented cytosolic activation of DNP to mutagens and the deactivation of the direct-acting mutagenicity of DNP by microsomes. In combination, as is the case with S9, the microsomal detoxifying activity outcompetes the cytosolic activation. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB In order to investigate the anticlastogenic effect of vanillin on ring-X loss, *D. melanogaster* females exposed to different vanillin concentrations were crossed with non-treated, MMC- or MMS-treated males. The results obtained with this in vivo investigation showed a significant inhibition of vanillin in the frequencies of spontaneous ring-X loss--59, 56, 38 and 36%--at the different concentrations used. In addition, vanillin treatment caused a significant suppression of MMC-induced ring-X loss. This decrease was observed only in the first 3 days after the interruption of vanillin treatment and at the concentrations of 0.5 and 1% of this flavoring agent. In contrast, vanillin did not show any effect on chromosome loss provoked by MMS. Therefore, the ring-X loss-decreasing effect of vanillin seemed to depend on the quality of DNA lesions and consequently on a specific enzymatic repair process present in the oocytes of *D. melanogaster*. PT JOURNAL-ARTICLE (ART).

AB Turmeric (*Curcuma longa* Linn.) has been shown to inhibit chemical carcinogenesis. In this study, we compared the chemopreventive efficacy of an aqueous turmeric extract (AqTE) and its constituents, curcumin-free aqueous turmeric extract (CFAqTE) and curcumin, using the *Salmonella typhimurium* mutagenicity assay and the bone marrow micronucleus test in female Swiss mice. AqTE exhibited *antimutagenic*

activity against direct-acting mutagens, 4-nitro-O-phenylenediamine and 1-methyl-3-nitro-1-nitrosoguanidine, in strains TA 98 and TA 100 respectively. Both AqTE and CFAqTE inhibited the mutagenicity of benzo α :pyrene in the two strains in the presence of Aroclor-1254-induced rat liver homogenate. The inhibition in both studies was dose-dependent. Administration of AqTE, CFAqTE and curcumin at a dose of 3 mg/animal 18 h prior to i.p. benzo α :pyrene injection (250 mg/kg) significantly inhibited bone marrow micronuclei formation in female Swiss mice by 43%, 76%, and 65% respectively. Furthermore, the incidence and multiplicity of forestomach tumours induced by benzo α :pyrene (1 mg/animal, twice weekly, p.o. for 4 weeks) in female Swiss mice were significantly inhibited by AqTE, CFAqTE and curcumin given 2 weeks before, during and after the carcinogen treatment. These data indicate that the protection against genomic damage by turmeric extract and its components tested could be necessary for some aspects of its cancer chemoprevention. Author-abstract.

JT PREVENTIVE MEDICINE.

PT JOURNAL-ARTICLE (ART).

AB Epidemiological evidence shows that green tea may be a factor in lowering cancer risk. We have investigated the possibility that (-)-epigallocatechin gallate (EGCG), a major polyphenol in green tea, might be an *antimutagenic* substance. In the Ames Salmonella test, EGCG suppressed the direct-acting mutagenicity of 3-hydroxyamino-1-methyl-5H-pyrido`4,3-b:indole (Trp-P-2(NHOH)) and 2-hydroxyamino-6-methyldipyrido`1,2-a:3',2'-d:imidazole (Glu-P-1(NHOH)), the activated forms of food-derived carcinogens 3-amino-1-methyl-5H-pyrido`4,3-b:indole and 2-amino-6-methyldipyrido`1,2-a:3',2'-d:imidazole. EGCG was also effective in reducing the mutagenicity of Trp-P-2(NHOH) in mouse FM3A cells in culture. Furthermore, EGCG demonstrated a suppressive effect in the in vivo Drosophila mutation assays, i.e., the wing spot test, and the DNA repair test, on several carcinogens. EGCG was also effective in inhibiting DNA single-strand breaks in vitro caused by Glu-P-1(NHOH). We conclude that the mechanism of inhibition may not have resulted from direct interaction between EGCG and the mutagens, but rather from indirect interception of mutagen action by EGCG. JT PREVENTIVE MEDICINE.
PT JOURNAL-ARTICLE (ART).
AB BACKGROUND. Tea from the *Camellia sinensis* species of the Theaceae family is one of the most ancient and, next to water, the most widely consumed beverage in the world. Since tea contains several polyphenols and since several other naturally occurring dietary polyphenols have shown *antimutagenic* effects in bacteria and anticarcinogenic effects in animal bioassay systems, we studied whether polyphenols extracted from Chinese green tea (GTP) also possess *antimutagenic* and anticarcinogenic effects. RESULTS. GTP and its constituent epicatechin derivatives were found to interact with hepatic cytochrome P450 (P450) and inhibited the P450-dependent mixed-function oxidase enzymes in skin and liver. GTP and its epicatechin derivatives exhibited *antimutagenic* effects in several test systems. GTP showed substantial anti-skin-tumor-initiating and anti-skin-tumor-promoting activities when assessed in murine skin tumorigenesis bioassay systems. In these model systems polycyclic aromatic hydrocarbons, benzo[a]pyrene (BP), 3-methyl-cholanthrene, 7,12-dimethylbenzo[a]anthracene, and (+)-7 beta,8 alpha-dihydroxy-9 alpha,10 alpha-epoxy-7,8,9,10-tetrahydrobenzo[a]pyrene (an ultimate carcinogenic metabolite of BP) were used as model skin carcinogens. The feeding of GTP in drinking water to SKH-1 hairless mice also afforded significant protection against ultraviolet-B-radiation-induced skin photocarcinogenesis. CONCLUSIONS. These data suggest that tea components possess *antimutagenic* and anticarcinogenic effects, and that they could protect humans against the risk of cancer by environmental agents. Author-abstract.

AB The application of antimutagenicity studies to human somatic mutation is discussed, with emphasis on the potential for future studies. Five assay-gene combinations are now available for measuring human somatic mutation in lymphocytes and erythrocytes. Results with these combinations have defined the human background levels, and show clear responses of mutant frequency to a variety of mutagens. The testing of *antimutagenic* effects on background frequencies is feasible, but has not yet been done. The major uncertainty in such studies is the unknown age of mutant cells in the background, since only the newly forming mutants are potentially susceptible to most *antimutagenic* treatments. Intervention studies in the face of active mutagenicity and the use of other genotoxicity endpoints, such as chromosome aberrations, micronuclei and DNA adducts, are considered briefly. AB Higher plants contain both mutagens and *antimutagens* and are susceptible to mutagenesis but screening programs for detection of antimutagenesis rarely employ higher plant systems. Short-term bacterial and mammalian tissue culture systems are the norm. Using modified screening tests for detecting *antimutagenic* agents, higher plants have been shown to contain a variety of structurally novel *antimutagenic* agents. Systematic bioassay-directed methodology resulted in the isolation in pure form and biological and chemical characterization of the responsible individual active components from various plants. The methodology in use is illustrated by the isolation of cinnamic acid, cinnamyl cinnamate and cinnamyl ricinoleate as the active constituents of the classic medicinal plant product, *Styrax asiatica*. The methods which may be used to reveal structure-activity relationships and to explore putative molecular modes of action are illustrated with excerpts from the same study. AB The extensive knowledge of the genetics of *Drosophila melanogaster* and the long experimental experience with this organism have made it of unique usefulness in mutation research and genetic toxicology. The development of somatic mutation and recombination tests (SMART) has provided sensitive, rapid and cheap assays for investigations of mutagenic and recombinogenic properties of chemicals. The present paper deals with the SMART wing spot assay, developed by Graf et al. (1984). The use of two genetic markers, multiple wing hair (mwh) and flare (flr) in the third chromosome, makes it possible to discern localized recombinogenic effects on the two intervals--the major, euchromatic, part of the chromosome, and the mostly heterochromatic centromere region. The distribution of induced mitotic recombination varied between test chemicals. Ethylene oxide caused a specific increase of twin spots, indicating a localized induction of somatic recombination in the centromere region. The wing spot assay has turned out to be suitable for combined treatment with chemicals in order to study *antimutagenic* and other modulating effects by mutagenic and recombinogenic chemicals. Examples of the use of this assay for such a purpose are presented in this paper. The inhibitor

of poly ADP-ribosylation, 3-aminobenzamide (3AB), caused a pronounced increase of wing spots, induced by alkylating agents. The data indicate that this interaction between alkylating agents and 3AB is solely due to an effect on somatic recombination but not on point mutations. The inhibitor of topoisomerases, novobiocin, which presumably acts on the chromatin configuration, had different modulating effects on spots induced by methyl methanesulfonate (MMS) and ethylnitrosourea (ENU). Novobiocin essentially acted as an antirecombinogenic agent in cotreatment experiments with MMS and as *antimutagenic* agent with ENU. Attempts to interfere with mutagenic and recombinogenic effects of the radical-generating agents bleomycin, menadione and paraquat, by agents acting on the defence mechanisms against oxygen radicals, were essentially unsuccessful. AB Basic and applied research on anticlastogenicity has not only revealed valuable evidence on the mechanisms governing the induction of chromosomal aberrations by environmental mutagens, but also contributed effective ideas on a practical employment of this knowledge for the protection of individuals at risk. Considering the basic role played by chromosomal anomalies in oncogenesis, additional weight must be attributed to studies on anticlastogenicity. The employment of human cells in this kind of study dates back to 1969/70, while classical mammalian cell systems were used only later on. Various modes of application of both clastogens and anticlastogens (AC) were examined, but simultaneous addition to the cultures of both reagents was the most favored way. A wide spectrum of cytogenetic endpoints can be studied, but differences can be demonstrated with regard to efficacy of inhibitors on different types of cytogenetic changes, e.g., open breaks vs. rearrangements, but also vs. SCEs. Depending on their mode of influence on this spectrum, ACs can be arranged in various categories which are of practical importance, for instance, with regard to their oncogenic potential. A wide variety of factors was shown to influence AC action, e.g., time and mode of application of the test substances, physiologic and metabolic features of the cell types studied, type and mechanism of the clastogen used, etc. The addition of S9 mix can drastically change the patterns of efficacy of the ACs. The combined application of two or more ACs, as far as investigated, apparently neither potentiates nor even merely adds their effects.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).
AB Short-term tests investigating genetic end-points in prokaryotes have
been extensively used worldwide not only for risk assessment purposes
but also for evaluating the modulation of the mutagenic response. In
spite of some intrinsic limitations, such as the lack of cell
compartmentalization or the need for an exogenous metabolic system
working extracellularly, experimental systems in bacteria can provide
useful preliminary indications and some information on the mechanisms
involved. In the large majority of studies the putative modulator is
mixed with a known mutagen and then assayed in target bacteria, with
suitable controls. However, under natural conditions exposure of

target cells to modulators may either precede, co-exist with, or follow exposure to mutagens. Therefore, a variety of methodological variations, involving pre-treatment, co-treatment, or post-treatment of bacteria with the putative modulator, have been designed. Application of these procedures showed that the effects of modulators can be completely upset, from inhibition to enhancement, or vice versa, by changing the experimental conditions. Use of methodological variations may provide more complete information on the spectrum of possible effects in bacteria as well as a better insight into modulation mechanisms. Several examples illustrating the flexibility of the Salmonella test in this field of research are available. On the other hand, the widespread use of these relatively simple techniques, yet requiring skillfulness and experience, may lead to some misuse or oversimplifications. A rather common inadequacy is to use excessive amounts of test mutagens, or to express the results in terms of revertants/survivors, rather than revertants/plate. In fact, in the Salmonella test the number of revertants is rather unrelated to the initial number of plated bacteria, provided a normal background lawn of bacterial growth is formed. Thus, a 50% killing of bacteria will not appreciably influence the number of revertants/plate, but expressed as revertants/survivors the effect will look twice as large.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).

AB The statistical methods for the analysis of mutagenicity and carcinogenicity underwent considerable theoretical-practical development following the need for assessing the mutagenic and carcinogenic potential of substances. Antimutagenicity is investigated through the analysis of respondents in dose-response assays, when two different molecules are administered separately and as a mixture to a respondent system. When the number of respondent units is high, and doses are orthogonal, it is possible to apply simple models such as analysis of variance. This is not always possible or common, and alternative approaches have been developed, based on multiple regression and on tables of proportions. In this work, some of the most frequently used methods for the assessment of joint responses are reviewed, particularly those based on multiple regression, such as the method of Shaeffer et al. and the method of Hass et al. In order to illustrate these methods, joint responses of perylene and cyclopentapyrene, of N-acetylcysteine and dinitropyrene,

and of N-acetylcysteine and extracts from diesel exhausts were analyzed. An antagonistic effect of perylene on the action of CPP was detected by the algorithm of Shaeffer et al. The effect is not multiplicative, i.e., it is not proportional to the product of doses. The *antimutagenic* effect of N-acetylcysteine on dinitropyrene is multiplicative, as detected by the method of Hass et al. The latter reveals that the inhibition by N-acetylcysteine on the mutagenic effect of extracts from diesel exhausts is also multiplicative. Author-abstract. 22 Refs.

AB Selected antimutagenicity listings and profiles have been prepared from the literature on the antimutagenicity of retinoids and the carotenoid beta-carotene. The antimutagenicity profiles show: (1) a single *antimutagen* (e.g., retinol) tested in combination with various mutagens or (2) *antimutagens* tested against a single mutagen (e.g., aflatoxin B1). Data are presented in the profiles showing a dose range for a given *antimutagen* and a single dose for the corresponding mutagen; inhibition as well as enhancement of mutagenic activity is indicated. Information was found in the literature on the testing of selected combinations of 16 retinoids and carotenoids vs. 33 mutagens. Of 528 possible *antimutagen-mutagen* combinations, only 82 (16%) have been evaluated. The most completely evaluated retinoids are retinol (28 mutagens), retinoic acid and retinol acetate (7 mutagens each), and retinal and retinol palmitate (6 mutagens each). beta-Carotene is the most frequently tested carotenoid (15 mutagens). Of the remaining retinoids and carotenoids, 8 were evaluated in combination with a single mutagen and the other 2 were tested against only 2 or 3 mutagens. Most of the data on antimutagenicity in vitro are available for *S. typhimurium* strains TA98 and TA100. Substantial data also are available for sister-chromatid exchanges in vitro and chromosome aberrations in vitro and in vivo. This report emphasizes the metabolic as well as the *antimutagenic* effects of retinoids in vitro and in vivo. Author-abstract. 49 Refs.

AB (-)Epigallocatechin gallate (EGCg) stimulated iodination of human
peripheral blood monocytes, polymorphonuclear cells (PMN), and human
promyelocytic leukemic HL-60 cells, dependent on time, dose, and
temperature. However, EGCg did not affect iodination of nonadherent
peripheral blood mononuclear cells, red blood cells, or 11 other
cultured cell lines. Although various immunoregulators such as
lipopolysaccharide (LPS), opsonized zymosan,
12-O-tetradecanoylphorbol-13-acetate (TPA) and tumor necrosis factor
stimulated PMN iodination to varying degrees, their ability to
stimulate monocyte iodination was much lower than that of EGCg.
Washout experiments demonstrated that contact with EGCg for less than
60 min irreversibly stimulated PMN and monocyte iodination. EGCg
also potently stimulated the production of interleukin-1-like factor
by monocytes. The data suggest that EGCg is a strong in vitro
stimulant of human phagocytes. Author-abstract.

AB A new compound, penta-acetyl geniposide ((Ac)5-GP), was obtained from
modified extract of Gardenia fructus (San-Jee-Chee in Chinese). The
structure of the compound was identified as
1-(beta-D-2',3',4',6'-tetraacetyl-glucopyrannosyloxyl)-1,4a,
5,7a-tetrahydro-7-(acetomethyl)-cyclopentapyran-4-carboxylic acid
methyl ester, according to the spectral data. The inhibitory effects
of (Ac)5-GP on aflatoxin B1 (AFB1)-induced cytotoxicity and DNA
damage were studied. In the investigation of the inhibitory effect
of (Ac)5-GP on AFB1-cytotoxicity, the plating efficiency of C3H10T1/2
cells in S-9 activation system was increased. In addition, (Ac)5-GP
inhibited the DNA damage of AFB1-treated C3H10T1/2 cells, and it
interfered with the inhibitory effect of DNA synthesis caused by
AFB1. These results suggest that the reduced DNA damage and the
increased DNA synthesis from cultured C3H10T1/2 cells are important
mechanisms for the inhibition of AFB1-cytotoxicity by (Ac)5-GP.

AB An in vitro T-lymphocyte cloning technique has been applied to study
the effects of JANUS fission-spectrum neutron irradiation and the
radioprotector S-2-(3-aminopropylamino) ethylphosphorothioic acid
(WR-2721) on the subsequent development of somatic mutations at the
hypoxanthine-guanine phosphoribosyl transferase (hprt) locus in
hybrid B6CF1 male mice. In control studies performed to establish an
in vitro cloning technique, the mutant frequencies of splenic
T-lymphocytes, as a result of exposure to a 100 cGy dose of neutrons,
increased with time from a control level of 9×10^{-7} to a maximum
value of 1.7×10^{-5} at 56 days following irradiation. Between 56
and 150 days after irradiation, mutant frequencies were observed to
plateau and remain stable. All subsequent determinations were
performed at 56 days following the experimental treatment of animals.

WR-2721 at a dose of 400 mg/kg was effective in protecting against the induction of hprt mutants (i.e. a mutant frequency reduction factor, MFRF) following the largest dose of neutrons used (i.e. 150 cGy), whether it was administered i.p. 30 min before, 5 min after, 3 h after, or three times at 3, 24, and 48 h after, as evidenced by MFRFs of 6.0, 6.6, 4.8 and 5.8 respectively. The *antimutagenic* effectiveness of WR-2721 administered 30 min prior to irradiation was unaffected, even when the dose was reduced to 200 mg/kg, MFRF = 7.0; 100 mg/kg, MFRF = 3.8; and 50 mg/kg, MFRF = 8.9. These findings confirm our earlier report using the radioprotector N-(2-mercaptoethyl)-1,3-diaminopropane (WR-1065) under in vitro conditions, and demonstrate that these agents can be used as effective *antimutagens* even when they are administered up to 3 h following radiation exposure. AB An antioxidative fraction was extracted from green tea and the major compounds in the fraction identified as epicatechins. Experimental results showed that green tea epicatechin compounds (GTEC) inhibited the mutagenicity and/or chromosomal damage caused by different carcinogens in both bacterial and mammalian cells. In vitro, GTEC inhibited transformation of BALB/3T3 cells induced by BP, X-rays, or MCA/TPA. In vivo, green tea extract decreased the incidence of carcinoma in the forestomach and esophagus of mice induced by sarcosine and NaNO₂. GTEC inhibited the development of gamma-glutamyl transpeptidase-positive foci in the livers of rats treated with diethyl nitrosamine (DEN) or DEN/phenobarbital. Our investigations indicate that the *antimutagenic* and anticarcinogenic mechanisms of GTBC are related to the following: increased glutathione-S-transferase activity; inhibition of edema, hyperplasia,

and ODC activity induced by TPA; free radical scavenging; blocked tumor promoter-induced inhibition of intercellular communication; and enhanced cell-mediated immunity. GTEC might be useful in the prevention of some kinds of cancer and a variety of oxidation-related diseases. Author-abstract. 21 Refs.

AB Ames test procedures were used to test 8 natural food extracts for their *antimutagenic* activity against the mutagenic activity induced

in *S. typhimurium* strains TA98 and TA100 by aflatoxin B1 (AFB1) or metabolic extracts from *A. versicolor* or *A. ochraceus*. The tested substances were extracted repeatedly with acetone. The revertants induced by AFB1, metabolic extracts of *A. versicolor* or *A. ochraceus* were significantly decreased when extracts of the 8 natural foods were added to the media. The results showed that these extracts had marked inhibitory effects on the mutagenic activity induced by AFB1 or metabolic extracts of the two molds and also suggested that *antimutagenic* substances were present in these natural foods. These experiments provide a scientific basis for the study of food substances for the prevention of carcinogenesis. It is considered that these 8 natural food extracts produce marked *antimutagenic* effects and are practically valuable in the field of chemoprophylaxis of liver cancer in humans. Author-abstract.

TI Effect of turmeric on urinary mutagens in smokers.

SO Mutagenesis. 1992 Mar. 7(2). P 107-9.

JT MUTAGENESIS.

PT JOURNAL-ARTICLE (ART).

AB Curcumin, the active principle of turmeric, is known to act as an anti-oxidant, anti-mutagen and anti-carcinogen in experimental animals. In the present study, anti-mutagenic effects of turmeric were assessed in 16 chronic smokers. It was observed that turmeric, given in doses of 1.5 g/day for 30 days, significantly reduced the urinary excretion of mutagens in smokers. In contrast, in six non-smokers, who served as control, there was no change in the urinary excretion of mutagens after 30 days. Turmeric had no significant effect on serum aspartate aminotransferase and alanine aminotransferase, blood glucose, creatinine and lipid profile. These results indicate that dietary turmeric is an effective anti-mutagen and it may be useful in chemoprevention. Author-abstract.

TI Influence of cinnamaldehyde on UV-induced gene conversion and point mutation in yeast: effect on protein synthesis.

SO Mutat-Res. 1992 May. 282(1). P 55-60.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB The activity of cinnamaldehyde (CIN), a bioantimutagen in bacterial systems, was tested in the D7 strain of yeast *Saccharomyces cerevisiae*. Yeast cells were UV-irradiated and post-incubated in liquid growth medium for 2 and 4 h with different concentrations of cinnamaldehyde. During the post-incubation period, DNA-damage-specific functions may be induced. This in turn may affect the genotoxicity and in fact a weak decrease in UV-induced revertant and revertant frequencies was observed after 4 h of post-incubation. The presence of CIN in the growth medium increased the UV-induced gene conversion and reversion. The addition of cycloheximide abolished this effect. To evaluate the CIN effect on protein synthesis, extracts of cells UV-treated and post-incubated for 2 h in the presence of 35S-methionine were performed. SDS-gel electrophoresis demonstrated the inhibitory effect of CIN on a UV-specific protein. This work suggests that CIN might interfere with DNA-damage-inducible systems although it did not exert an *antimutagenic* activity in our experimental conditions. Author-abstract.

TI Effects of various chemical compounds on spontaneous and hydrogen peroxide-induced reversion in strain TA104 of *Salmonella typhimurium*.

SO Mutat-Res. 1992 Apr. 266(2). P 77-84.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB In experiments designed to determine which active oxygen species contribute to hydrogen peroxide (HP)-induced reversion in strain

TA104 of *Salmonella typhimurium*, 1,10-phenanthroline (an iron chelator, which prevents the formation of hydroxyl radicals from HP and DNA-bound iron by the Fenton reaction), sodium azide (a singlet oxygen scavenger), and potassium iodide (an hydroxyl radical scavenger) inhibited HP-induced reversion. These results indicate that hydroxyl radicals generated from HP by the Fenton reaction, and perhaps singlet oxygen, contribute to HP-induced reversion in TA104. However, reduced glutathione (reduces Fe³⁺ to Fe²⁺ and/or HP to water), diethyldithiocarbamic acid (an inhibitor of superoxide dismutase), diethyl maleate (a glutathione scavenger), and 3-amino-1,2,4-triazole (an inhibitor of catalase) did not inhibit HP-induced reversion in TA104. Thus, superoxide radical anions and HP itself do not appear to be the cause of HP-induced reversion in this strain. In experiments on the effect of 5 common dietary compounds (beta-carotene, retinoic acid, and vitamins A, C and E), chlorophyllin (CHL), and ergothioneine, the frequency of revertants in TA104 increased above the spontaneous frequency in the presence of beta-carotene or vitamin C (about 2-fold) or vitamin A (about 3-fold). The 5 dietary *antimutagens* and CHL did not inhibit HP-induced reversion in TA104. However, L-ergothioneine inhibited HP-induced reversion in this strain. Therefore, it is likely that L-ergothioneine is a scavenger of hydroxyl radicals or an inhibitor of their formation, and perhaps of singlet oxygen, at the concentrations tested in TA104. Author-abstract.

SO Mutat-Res. 1992 Apr. 266(2). P 205-13.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Pyridoxal (PL) and pyridoxal 5'-phosphate (PLP) showed a marked *bio-antimutagenic* effect on UV-induced mutagenesis in *E. coli* B/r WP2, but not in the DNA excision repair-deficient strain WP2suvrA under the condition where no cellular toxicity was observed. No delay in the first cell division was seen on post-treatment with PL after UV irradiation. PL reduced not only UV- but 4-nitroquinoline-1-oxide-induced mutation, while it was ineffective in N-methyl-N'-nitro-N-nitrosoguanidine- or gamma-ray-treated cells. These results suggest that PL promotes DNA excision repair directly or indirectly and the decrease in the amount of unrepaired DNA damage might cause the reduction of UV-induced mutations in *E. coli* B/r WP2. In addition to the above observation, PLP reduced the frequency of mitomycin C- (2 mg/kg, i.p.) induced micronuclei in mouse peripheral blood cells. Simultaneous or subsequent oral administration of PLP (25 mg/kg) decreased the frequency of micronucleated peripheral

reticulocytes. Author-abstract.

TI Stable superoxide dismutase (SOD)-mimetic ternary human serum albumin-Cu(II)(3,5-diisopropylsalicylate)₂/Cu(II)₂(3,5-diisopropylsalicylate)₄ complexes in tissue distribution of the binary complex.

SO Biochem-Pharmacol. 1992 Apr 1. 43(7). P 1601-12.

JT BIOCHEMICAL PHARMACOLOGY.

PT JOURNAL-ARTICLE (ART).

AB Copper(II)₂(3,5-diisopropylsalicylate)₄ `Cu(II)₂(3,5-DIPS)₄: has been found to have antiinflammatory, antiulcer, anticancer, anticonvulsant, *antimutagenic,* antidiabetic, analgesic, and radiation protection and recovery activities. It has also been found to reduce ischemia-reperfusion injury. Because of these activities it was of interest to understand how this compound is transported in the body to affected tissues. Evidence supporting the suggested formation of ternary human serum albumin (HSA)-Cu(II)(3,5-DIPS)₂ or Cu(II)₂(3,5-DIPS)₄ complexes was obtained using ultraviolet spectrophotometry, dialysis, and atomic absorption spectrophotometry or atomic emission spectroscopy. Superoxide dismutase (SOD)-mimetic activity was also determined using the xanthine/xanthine oxidase/cytochrome c system. Ultraviolet spectra of aqueous solution mixtures of Cu(II)₂(3,5-DIPS)₄ in equilibrium with 2Cu(II)(3,5-DIPS)₂ and HSA as well as aqueous solutions of solid Cu(II)₂(3,5-DIPS)₄ obtained by stirring the solid with an aqueous solution of HSA showed no obvious change in absorbance to indicate ternary complex formation. However, comparison of ultraviolet spectra taken before and after dialysis supports the suggested bonding of Cu(II)(3,5-DIPS)₂ or Cu(II)₂(3,5-DIPS)₄ to HSA. Comparison of copper concentrations before and after dialysis also supports the suggested bonding of Cu(II)(3,5-DIPS)₂ or Cu(II)₂(3,5-DIPS)₄ to HSA. Based upon these data it is plausible that Cu(II)(3,5-DIPS)₂ or Cu(II)₂(3,5-DIPS)₄ form stable ternary complexes with HSA. These stable ternary complexes were also found to have SOD-mimetic activity. TI *Antimutagenic* effect of Maillard browning products obtained from amino acids and sugars.

SO Food-Chem-Toxicol. 1992 Feb. 30(2). P 127-32.

JT FOOD AND CHEMICAL TOXICOLOGY.

PT JOURNAL-ARTICLE (ART).

AB The *antimutagenic* effects of Maillard reaction products (MRPs) prepared by heating three sugars (fructose, glucose and xylose) and four amino acids (arginine, glycine, lysine and tryptophan) at 100 degrees C for 10 hr was evaluated in the Salmonella/microsome assay. The highest extent of browning was found in the MRPs of sugars-lysine and xylose-amino acids. The MRPs of xylose-amino acids showed stronger antioxidative activity and reducing power than did the other combinations. No mutagenicity or toxicity in Salmonella typhimurium TA98 was observed with any of the MRPs in the presence of S-9. Most MRPs, especially those of sugars-tryptophan and xylose-amino acids, strongly inhibited the mutagenicity of 2-amino-3-methylimidazo(4,5-f)quinoline (IQ), 3-amino-1,4-dimethyl-5H-pyridol-(4,3-b)indole (Trp-P-1) and 2-amino-6-methyldipyrido(1,2-a:3',2'-d)imidazole (Glu-P-1) in the presence of S-9. However, the MRPs of fructose-glycine and fructose-arginine increased the mutagenicity of Trp-P-1. The *antimutagenic* effect of the MRPs was well correlated with their antioxidative activity and reducing power. The mutagenicity of benzo`a:pyrene was moderately inhibited by most MRPs, but was increased by the MRP of glucose-arginine. Aflatoxin B1 mutagenicity was increased greatly by all the MRPs except that of xylose-tryptophan. The findings suggested that MRPs might have a bifunctional property of co-mutagenicity and antimutagenicity in certain cases. Author-abstract.

SO Mutagenesis. 1991 Nov. 6(6). P 501-6.

JT MUTAGENESIS.

PT JOURNAL-ARTICLE (ART).

AB Eight furocoumarins differing in their basic structure and substitution pattern (angular, linear, dihydrofuran type) were tested for their ability to reduce the mutagenic potency of dictamnine and

rutacridone, two alkaloids present in extracts from *Ruta graveolens* L. Both compounds need metabolic activation by S9 mix in order to exhibit mutagenicity in *Salmonella typhimurium* strain TA98. The furocoumarins used in this study did not show any mutagenicity either with or without S9 mix within the dose range tested. However, all the furocoumarins were able to inhibit the mutagenicity induced by dictamnine as well as by rutacridone in a dose-dependent manner. Imperatorin turned out to be the most efficient inhibitor. The inhibitory effect is probably due to the inactivation of the cytochrome P450 enzyme complex which prevents the activation of the promutagens. This is indicative of the desmutagenic character of the furocoumarins. However, there is also some evidence that the reduction of the mutagenicity induced by dictamnine might be caused to a small extent by a mechanism which possibly depends on the competition with furocoumarins for the same sites in the DNA molecule. TI Protection against AZT-induced mutagenesis at the HGPRT locus in a human cell line by WR-151326.

SO Int-J-Radiat-Oncol-Biol-Phys. 1992. 22(4). P 813-5.

JT INTERNATIONAL JOURNAL OF RADIATION ONCOLOGY, BIOLOGY, PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB The anti-AIDS agent, AZT (3'-azido-3'-deoxythymidine), is mutagenic in a cultured human hepatoma cell line designated HepG2 at the HGPRT (hypoxanthine-guanine phosphoribosyl transferase) locus. Using an exposure time of 3 hr, the number of mutants per 10^6 surviving cells increased as a function of AZT dose from 125 to 520. Chinese hamster ovary cells, in contrast, are not affected with respect to this endpoint when similar concentrations of AZT are used (i.e., 0.1 to 10 mg/ml). The aminothiols WR-151326 (3-(3-methylaminopropylamino) propanethiol dihydrochloride) was evaluated as a possible *antimutagen* for use with AZT. At a concentration of 4 mM, WR-151326 was added either concomitantly or following exposure of HepG2 cells to a 5 mg/ml concentration of AZT. Regardless of the treatment condition, WR-151326 was effective in reducing the mutagenic effects of AZT by about a factor of 2. Correcting for background mutations, the mutation frequencies determined were: AZT only for 3 hr, 110×10^{-6} (S.E.M. $\pm 6.0 \times 10^{-6}$); AZT together with WR-151326 for 3 hr, 57×10^{-6} (S.E.M. $\pm 3.0 \times 10^{-6}$); and AZT for 3 hr followed by WR-151326 for 3 hr, 68×10^{-6} (S.E.M. $\pm 5.0 \times 10^{-6}$). This study demonstrates that AZT is mutagenic to a cell line of human origin and that WR-151326 can protect against this mutagenic process. Author-abstract.

TI Inhibition of 2-amino-3-methylimidazo`4,5-f:quinoline-DNA adduct formation in CDF1 mice by heat-altered derivatives of linoleic acid.

SO Food-Chem-Toxicol. 1992 Jan. 30(1). P 9-16.

JT FOOD AND CHEMICAL TOXICOLOGY.

PT JOURNAL-ARTICLE (ART).

AB Grilled ground beef contains a number of carcinogens, including aminoimidazoazaarenes, such as 2-amino-3-methylimidazo`4,5-f:quinoline (IQ), as well as anticarcinogenic substances, such as heat-generated derivatives of linoleic acid (CLA). In the present study, CLA was administered by gavage every other day to young adult CDF1 mice for a period of 45 days (50 microliters/48 hr for days 1-24 and 100 microliters/48 hr for days 25-45), using trioctanoin as a control. On day 46 all animals received a single oral dose (50 mg/kg) of IQ and tissues were collected 24 hr later. Tissue DNA was purified and analysed for IQ-DNA adducts by 32P-postlabelling assays. Compared with controls, CLA treatment caused a 43.1 and 31.8% inhibition of adduct formation in the livers of male and female mice, respectively. In the lung and large intestine CLA had a 74.2 and 39.4% inhibitory effect, respectively, in the female only, whereas there was no effect in the stomach or small intestine of either sex. In the kidneys of females, CLA treatment inhibited IQ-DNA adduct formation almost completely (95.2%), whereas in the kidneys of males CLA had no effect. It is concluded that CLA inhibits IQ-DNA adduct formation in certain IQ target organs (liver and lung) and non-target organs (large intestine, kidney), but is inactive in other target organs (stomach) and non-target organs (small intestine) of the CDF1 mouse. TI Phenobarbital: does the positive result in TA1535 indicate genotoxic properties?

SO Environ-Mol-Mutagen. 1992. 19(2). P 161-6.

JT ENVIRONMENTAL AND MOLECULAR MUTAGENESIS.

PT JOURNAL-ARTICLE (ART).

AB The liver carcinogen phenobarbital (PB) causes a weak but reproducible increase of the mutant frequency in the Ames test, strain TA1535, without S9. Since there is no obvious chemical basis for a "DNA reactivity" of this compound experiments were performed to obtain information about possible indirect mechanisms of enhancing the number of spontaneous mutant colonies. In the course of the study strong synergistic and comutagenic effects of PB when given in combination with Na-azide or 2-aminoanthracene (2AA) were observed. Not only TA1535 but the complete set of tester strains was

responsive. However, PB did not enhance the effects of other mutagens such as 4-nitroquinoline N-oxide or 2-nitrofluorene. It is argued that in strain TA1535 the fixation and expression of spontaneously occurring DNA lesions is amenable to modulation by PB similar to that of Na-azide or 2AA induced lesions. Thus in the usual sense, PB is not genotoxic in the Ames test. Methapyrilene, another liver carcinogen with an assumed nongenotoxic mode of action, showed almost identical properties in these experiments.

TI Chinese medicinal herbs modulate mutagenesis, DNA binding and metabolism of benzo`a:pyrene 7,8-dihydrodiol and benzo`a:pyrene 7,8-dihydrodiol-9,10-epoxide.

SO Cancer-Lett. 1992 Feb 29. 62(2). P 123-31.

JT CANCER LETTERS.

PT JOURNAL-ARTICLE (ART).

AB Oldenlandia diffusa(OD) and Scutellaria barbata (SB) have been used in traditional Chinese medicine for treating liver, lung and rectal tumors. In this study, the effects of aqueous extracts of these two herbs on benzo`a:pyrene 7,8-dihydrodiol. (BaP 7,8-DHD) and benzo`a:pyrene 7,8-dihydrodiol-9,10-epoxide (BPDE)-induced mutagenesis using Salmonella typhimurium TA100 as the bacterial tester strain and rat liver 9000 x g supernatant (S9) as the metabolic activation system were assessed. We also determined the effects of these two herbs on BaP 7,8-DHD and BPDE binding to calf thymus DNA. Organosoluble metabolites of BaP 7,8-DHD and water-soluble conjugates of BaP 7,8-DHD and BPDE were analyzed by high-performance liquid chromatography (HPLC) and alumina column liquid chromatography. Mutagenesis assays revealed that these two herbs produced a significant concentration-dependent inhibition of histidine-independent (His+) revertants induced by BaP 7,8-DHD and BPDE. OD and SB also inhibited BPDE-induced mutagenesis in a concentration-dependent manner in the absence of S9. SB had a greater inhibitory effect than OD. SB significantly inhibited BaP 7,8-DHD and BPDE binding to DNA while OD significantly enhanced DNA binding of both compounds. OD and SB inhibited the formation of organosoluble metabolites of BaP 7,8-DHD and decreased the formation of water-soluble conjugates of BaP 7,8-DHD and BPDE. However, the fraction of the total radioactivity in the water-soluble conjugates present as sulfate and glutathione was increased by OD and SB. Glucuronide fraction was decreased. The results of this study affirm our previous work suggesting that these two Chinese medicinal herbs possess *antimutagenic* properties and further suggest that they act as blocking agents through a scavenging mechanism. TI Fecapentaene excretion and fecal mutagenicity in relation to nutrient
intake and fecal parameters in humans on omnivorous and vegetarian
diets.

SO Cancer-Lett. 1992 Feb 14. 62(1). P 11-21.

JT CANCER LETTERS.

PT JOURNAL-ARTICLE (ART).

AB Fecapentaenes are strong fecal mutagenic compounds presumably
occurring in the majority of Western human individuals, and are
possibly essential initiators of colon carcinogenesis. Dietary
factors have been shown to influence colorectal cancer risk and to
modulate both fecal mutagenicity and fecapentaene concentrations.
Therefore, in this study, excretion of fecapentaenes is determined in
humans consuming either vegetarian or omnivorous diets. The results
show that the most predominant fecapentaene forms are excreted in
higher concentrations by vegetarians. Consumption of cereal fiber,
calcium and carotene as well as fecal concentrations of
iso-lithocholic acid were found to correlate positively with excreted
concentrations of one or more fecapentaene analogues. On average,
22% of excreted fecapentaene concentrations was found to be related
to nutrient intake in stepwise regression models. Dietary calcium
intake was found to be the most significant factor positively
correlating with excreted fecapentaene concentrations. Intake of
mono-unsaturated fatty acids or fiber from vegetables and fruit could
be shown to correlate with fecapentaene excretion to a lesser degree.
Despite high fecapentaene concentrations in fecal dichloromethane
extracts, only 1 out of 20 samples revealed significant mutagenic
activity in Salmonella typhimurium TA 100. Further, aqueous extracts
of feces from omnivores appeared to be equally mutagenic as feces
from vegetarians and contained non-detectable concentrations of
fecapentaenes. It is concluded that dietary factors do affect
excreted fecapentaene levels, but only to a relatively minor extent.
Since vegetarians at low risk for colorectal cancer excrete higher
concentrations of fecapentaenes, it could be hypothesized that
relatively increased fecapentaene excretion in combination with
antimutagenic compounds in feces represents colon cancer prevention.

TI *Antimutagenic* effects of radioprotector WR-2721 against
fission-spectrum neutrons and ⁶⁰Co gamma-rays in mice.

SO Int-J-Radiat-Biol. 1992 Mar. 61(3). P 387-92.

JT INTERNATIONAL JOURNAL OF RADIATION BIOLOGY.

PT JOURNAL-ARTICLE (ART).

AB The *antimutagenic* effects of the radiation protective agent, S-2-(3-aminopropylamino)ethylphosphorothioic acid (WR-2721), were studied against fission-spectrum-neutron- and ^{60}Co -gamma-ray-induced mutagenesis in mice. Mutagenesis at the hypoxanthine-guanine phosphoribosyl transferase (hprt) locus was measured 56 days following whole-body irradiation with JANUS neutrons (single doses, 50-150 cGy) or ^{60}Co photons (single doses, 250-750 cGy). Splenic T lymphocytes from B6CF1 mice were grown in round-bottomed 96-microwell culture plates with or without the selective agent 6-thioguanine (6-TG). The mutant frequency, as a result of exposure to neutrons or ^{60}Co photons, increased 100-fold with dose. Doses of 150 cGy neutrons and 750 cGy ^{60}Co photons were equally mutagenic. When animals were injected with WR-2721 at a dose of 400 mg/kg body weight, i.p., 30 min before whole-body irradiation with JANUS neutrons or ^{60}Co photons, mutant frequencies were significantly reduced at all radiation doses (i.e. protection factors of 1.4 and 2.4, respectively). Thus, the aminothiols are effective *antimutagens.* A novel clinical application of these compounds could be in their use to protect against radiation- and/or chemotherapy-induced genotoxic damage to normal cells.

TI The effects of dNTP pool imbalances on frameshift fidelity during DNA replication.

SO J-Biol-Chem. 1992 Feb 25. 267(6). P 3589-96.

JT JOURNAL OF BIOLOGICAL CHEMISTRY.

PT JOURNAL-ARTICLE (ART).

AB The use of unequal concentrations of the four deoxynucleoside triphosphates (dNTPs) in DNA polymerization reactions alters base substitution error rates in a predictable way. Less is known about the effects of substrate imbalances on base addition and deletion error rates. Thus, we examined pool bias effects on frameshift fidelity during DNA synthesis catalyzed by replicative DNA polymerases. Imbalanced pools altered the frameshift fidelity of the human immunodeficiency virus type-1 reverse transcriptase. Both mutagenic and *antimutagenic* effects were observed for minus-one, plus-one, and minus-two nucleotide errors, in a highly sequence-specific manner. Most of this specificity can be rationalized by either of two models. One involves frameshifts initiated by pool bias-induced nucleotide misinsertion, and the other involves pool bias-initiated template-primer slippage. Several examples of complex mutations were also recovered more than once in

small mutant collections. These contained closely spaced single-base substitution and minus-one base frameshift changes. The two changes occurred at a frequency much higher than predicted if they were generated independently. This suggests that when the polymerase makes one mistake, the probability that it will make a second mistake within the next few incorporations increases significantly. Perturbation of dNTP pools also affected the frameshift fidelity of the replicative yeast DNA polymerase alpha. In reactions containing a low concentration of one dNTP, the error rate increased for one-nucleotide deletions at homopolymeric template nucleotides complementary to the dNTP whose concentration was low. We extended this approach to determine the frameshift fidelity of simian virus 40 origin-dependent semiconservative replication of double-stranded DNA in extracts of human cells. In reactions performed with an equal concentration of all four dNTPs, replication was highly accurate for minus-one-nucleotide errors. However, when the concentration of one dNTP was decreased, the replication error rate increased at complementary, homopolymeric template positions. This response provides an approach for describing frameshift accuracy during replication of the leading and lagging strands. Author-abstract.

TI `Manifestation of *antimutagenic* activity of "dark" repair under alternative levels of aeration of UV-irradiated bacteria:.

SO Genetika. 1991 Sep. 27(9). P 1499-502.

JT GENETIKA.

PT JOURNAL-ARTICLE (ART).

AB The cease of aeration of UV-irradiated bacteria incubated in glucose-salt medium does not affect *antimutagenic* activity of excision repair in Escherichia coli cells but strongly inhibits that in Bacillus subtilis cells. It has been suggested that these differences are connected with various possibilities for energy (ATP) production in facultative anaerobe, which is E. coli, and obligate anaerobe, Bac. subtilis. The absence of noticeable influence of the aerobiosis----anaerobiosis shift on the kinetics of disappearance of potential mutations in E. coli cells is interpreted in terms of existence of a mechanism regulating the expenditure of cell energy reserve upon repair process. It is suggested that the low rate of disappearance of potential mutations observed in post-irradiation conditions favourable for protein synthesis is a consequence of limited supply of energy to repair process at some sites of cellular DNA, due to great expense of energy for protein synthesis. JT CARCINOGENESIS.

PT JOURNAL-ARTICLE (ART).

AB Chlorophyllin (CHL), a sodium/copper salt of chlorophyll used in the treatment of geriatric patients, exhibits potent *antimutagenic* activity in a range of assays in vitro and in vivo. The protective effects of CHL were studied in Sprague-Dawley rats using inhibition of carcinogen-DNA binding as an end-point. Animals were administered CHL (150 mg/kg body wt) and [2-14C]-2-amino-3-methylimidazo[4,5-f]quinoline (IQ, 50 mg/kg body wt) by single oral gavage. Covalent IQ-DNA binding in liver was determined 8, 24 and 48 h after dosing; CHL inhibited binding at these times by 58, 56 and 46% respectively, compared with rats given IQ alone. The total liver burden of IQ-derived radioactivity was reduced in CHL-treated rats, as was the total amount of radiolabel eliminated in the urine and bile. However, elimination via the feces was increased in rats given CHL, both in terms of total radiolabel eliminated and amount of unmetabolized IQ in dichloromethane extracts of feces. Finally, pretreatment with CHL in the drinking water, or injection of CHL into isolated loops of intestine in situ, reduced the absorption of IQ from the gut. Collectively, these findings indicate that, when administered simultaneously with the carcinogen, CHL attenuates IQ-DNA binding in rat liver by interacting with IQ in the gut and reducing carcinogen uptake, distribution and metabolism. The results suggest that further studies should be conducted with respect to the protective mechanisms and possible anti-carcinogenic properties of CHL. Author-abstract.

TI The protective effect of beta-carotene on genotoxicity induced by cyclophosphamide.

SO Mutat-Res. 1992 Feb. 265(2). P 237-44.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB The influence of beta-carotene on the clastogenicity of the indirect-acting mutagen cyclophosphamide (CPA) was investigated in mice, in vivo, for the induction of chromosome aberrations in bone marrow cells (BM). beta-Carotene (0.5, 1.0, 2.0, 5.0, 10, 25, 50, 100 and 200 mg/kg) was administered by gavage for 5 consecutive days. 4 h after the last treatment with beta-carotene, the mice were injected intraperitoneally with CPA, and the BM cells were fixed after 16, 24 and 32 h for the evaluation of the frequency of

chromosome aberrations. The results showed that beta-carotene was effective in reducing chromosomal damage induced by CPA with the increase of its concentration up to a level after which this effect was not observed. This anticlastogenicity was better detected when the cells were fixed at 32 h, although a tendency in reducing the CPA clastogenicity was already observed at 16 and 24 h. Our results suggest that beta-carotene provides significant protection against the genotoxicity of CPA, although no dose-effect relationship on the frequencies of cells with chromosomal aberrations was observed. PT JOURNAL-ARTICLE (ART).
AB A set of stable nitroxide free radicals that are used as spin labels have been shown to possess metal-independent superoxide dismutase-like activity. Unlike superoxide dismutase (SOD), these compounds are low molecular weight, and readily penetrate into the cell. A representative nitroxide, 4-hydroxy-2,2,6,6-tetramethylpiperidinyloxy (Tempol), was investigated for *antimutagenic* activity in the XPRT forward mutation assay in CHO AS52 cells. AS52 cells were exposed to hydrogen peroxide, or the hypoxanthine/xanthine oxidase superoxide generating system, in the presence or absence of 10 mM Tempol. Tempol itself was not mutagenic or toxic to AS52 cells. Tempol protected cells nearly completely from the cytotoxic and mutagenic effects of hydrogen peroxide and hypoxanthine/xanthine oxidase. We have previously shown that nitroxides do not alter the extracellular concentration of hydrogen peroxide, and that they are taken up by mammalian cells, suggesting that the *antimutagenic* activity of Tempol is an intracellular phenomenon. PT JOURNAL-ARTICLE (ART).
AB Dietary spice components have been screened for their protective

effect against reactive oxygen species (ROS)-induced, lipid peroxide-mediated membrane and DNA damage and mutagenicity. A new, water soluble, 5-kDa peptide--Turmerin--from turmeric (*Curcuma longa*) has been found to be an efficient

antioxidant/DNA-protectant/antimutagen. Turmerin forms 0.1% of the dry weight of turmeric and is obtained in a crystalline form. It is a heat stable, noncyclic peptide containing 40 amino acid residues, with a blocked N-terminal and leucine at the C-terminal. It is insensitive to trypsin and pepsin, heat, and uv radiation. Turmerin contains three residues of methionine which are partly responsible for the antioxidant activity. Turmerin at 183 nM offers 80% protection to membranes and DNA against oxidative injury. ROS-induced arachidonate release and the mutagenic activity of t-butyl hydroperoxide are substantially inhibited by Turmerin. Turmerin is noncytotoxic up to milligram concentrations, as tested by Ames assay and in human lymphocytes. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB The *antimutagenic* effect of dialysed cell extracts of 4 strains of propionic acid bacteria was examined against the mutagenicity of sodium azide in the TA1535 tester strain of Salmonella typhimurium using the Ames test. It was noted that dialysates of 2 strains of Propionibacterium shermanii, P. pentosaceum and P. acnes, significantly reduced sodium azide-induced revertants. The dialysate of propionic acid cocci did not show an *antimutagenic* effect. The inhibitory activity was enhanced if the mutagen and extract were coincubated for 20 min prior to performing the mutagenicity assay. Antimutagenicity of dialysates from P. shermanii VKM-103 against MNNG and 9-aminoacridine was shown in S. typhimurium strains TA1535 and TA97. The *antimutagenic* activity was found in the protein fraction of the cell extract of P. shermanii. The proteins of the dialysate of P. shermanii were separated using a Toyopearl gel column into 3 main peaks according to their molecular weights. The *antimutagenic* activity towards sodium azide was found in the second and the third peaks. We suggest that dialysates of the cells of propionic acid bacteria contain several kinds of *antimutagenic* substances with different molecular weights. Author-abstract.

SO Mol-Gen-Mikrobiol-Virusol. 1991 Jul. (7). P 20-2.

JT MOLEKULIARNAIA GENETIKA, MIKROBIOLOGIA, I VIRUSOLOGA.

PT JOURNAL-ARTICLE (ART).

AB The initial rates of *antimutagenic* dark repair were measured in Escherichia coli WP2 trpE65 cells irradiated by UV-light (11 J/m²) and then incubated in liquid media of various compositions. Samples were taken from suspension of incubated bacteria every 5 min following irradiation, mixed with acriflavine to block further repair and plated onto the selective medium containing acriflavine (1 micrograms/ml) to score the Trp⁺ mutations. The initial rate of *antimutagenic* repair was estimated from the kinetics of disappearance of mutations in several successive probes. It appeared to depend on the composition of a medium, to establish just after placing irradiated bacteria onto the medium and to decrease significantly in irradiated cells incubated under conditions favourable for growth. The decrease was not due to inhibition of postreplicative repair and was not caused by casaminoacids as such, but by combination of growth factors that provided the intensive protein synthesis. The decrease could be responsible for a strong mutational response of bacteria to irradiation because it secures the survival of premutagenic lesions in DNA till mutation fixation. It is suggested that metabolic regulation of the *antimutagenic* repair activity exists, based on an active switch of the energy flows required for several parallel metabolic pathways that proceed in irradiated cells. JT AMERICAN JOURNAL OF CLINICAL NUTRITION.

PT JOURNAL-ARTICLE (ART).

AB Actinomycetes, involved in oral and periodontal diseases, cause serious infections in immunocompromised hosts. Severely scorbutic

guinea pig leukocytes killed only 12% of phagocytosed actinomycetes, had distorted nuclear morphology, had 16 times less ascorbate, and had no chemotactic responses in vitro. Ascorbate reversed these indices and also prevented nitrosamine formation by oral organisms. Degranulating leukocytes release lactoferrin and ascorbate that chelate iron, essential for microorganisms. Ascorbic acid, 2,2'-bipyridine and 1,10-phenanthroline were bactericidal to several bacterial pathogens at millimolar concentrations. Iron alone reversed this effect. In in vivo experiments an *Actinomyces viscosus* monoflora was implanted in rhesus monkeys. Plaque and serum samples showed decreased (by six orders of magnitude) bacterial counts and decreased actinomycete antibody titers in animals given 1 g ascorbate/d. Removing ascorbate returned counts and titers to preascorbate concentrations. Fifteen marmosets, receiving twice daily topical applications of ascorbate or water, had comparatively lower gingival, calculus, and plaque indices and only slightly lowered actinomycete counts. JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Nordihydroguaiaretic acid (NDGA), which occurs in the resinous exudates of many plants is used as an antioxidant in fats and oils. In this study we show that NDGA inhibited the mutagenicity of methyl methanesulfonate, benzo`a:pyrene (BP), 2-aminofluorene, and aflatoxin B1 in Salmonella typhimurium strain TA100 or TA98 in the absence and presence of rat hepatic microsomal activation system. The addition of NDGA during and after nitrosation of methylurea (MU) resulted in a dose-dependent inhibition of mutagenicity induced by nitrosation products of MU. In a two-stage skin tumorigenesis protocol using 7,12-dimethylbenz`a:anthracene (DMBA) as the initiating agent followed by twice weekly applications of 12-O-tetradecanoylphorbol-13-acetate (TPA) as tumor promoter, pretreatment of animals with NDGA prior to DMBA application, afforded significant protection against skin tumorigenicity in female SENCAR mice. In additional studies, skin application of NDGA also inhibited the binding of topically applied `3H:BP and `3H:DMBA to epidermal DNA. When assessed in the anti-tumor promotion protocol, pretreatment of animals with NDGA before each application of TPA in DMBA-initiated mouse skin, resulted in 72% decrease in the total number of tumors when compared to non-NDGA pretreated animals. The possible mechanism(s) of the *antimutagenic* and anti-tumorigenic activities may be due to the multiple effects of NDGA as inhibitor of the carcinogen metabolism and DNA-adduct formation, scavenger of carcinogen free radicals, and as inhibitor of TPA-induced ornithine decarboxylase activity. SO Mutat-Res. 1991 Nov. 251(1). P 71-7.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB The effect of caffeine and cycloheximide during the G2 phase on frequency of chromosomal aberrations and G2 duration was studied in control and X-ray-irradiated human lymphocytes in vitro. Caffeine treatments alone increase the frequencies of chromatid breakage and decrease the average G2 duration in control and X-ray-irradiated lymphocytes (40 R). Both caffeine effects are reversed by 0.5 micrograms/ml cycloheximide in combination treatments. Cycloheximide treatments alone prolong G2 duration in control as well as in X-ray-irradiated lymphocytes although no improvement in chromosome repairing by this inhibitor of protein synthesis was observed under the conditions of our experiments. We propose that the cycloheximide

effect is associated with a low level of mitotic factors, required for the entrance into mitosis, which is maintained at a higher level in caffeine treatment alone. Finally, G2 delay has generally been associated with certain genome damage. The fact that the caffeine and cycloheximide effects on X-irradiated lymphocytes are also present in control lymphocytes (without X-rays) suggests that control of the G2 duration constitutes one of the mechanisms involved in DNA repair operating during the G2 phase. TI The metabolic activation of 4-nitro-o-phenylenediamine by chlorophyll-containing plant extracts: the relationship between mutagenicity and antimutagenicity.

SO Mutat-Res. 1991 Sep-Oct. 250(1-2). P 79-86.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Chlorophyllin, the sodium and copper salt of chlorophyll, chlorophyll a, and chlorophyll b were tested for their ability to inhibit the mutagenic activity of the direct-acting mutagen 4-nitro-o-phenylenediamine (NOP) and its plant-activated mutagenic enhancement. All three forms of chlorophyll were *antimutagenic* against both NOP and its plant-activated product, with chlorophyllin proving most effective. Chlorophyll-containing plant extracts, however, proved very efficient at activating NOP into a mutagen of greater potency. When these extracts were assayed for total chlorophyll content it was found that they contained far less chlorophyll than was required for an *antimutagenic* effect to occur. Thus, the balance between chemical mutagen activation and/or enhancement by chlorophyll-containing plant extracts and the potential antimutagenicity of these plant extracts is a function of chlorophyll concentration. The data presented here indicate that this balance must be taken into consideration in future studies investigating the efficacy of complex natural plant extracts as *antimutagenic* substances. JT AMERICAN JOURNAL OF MEDICINE.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-ACADEMIC (RAC).

AB Our studies provide evidence that thiols, such as N-acetyl-L-cysteine, inhibit both spontaneous mutations and induced

mutations in bacteria, prevent the in vivo formation of carcinogen-DNA adducts, and suppress or delay the development of tumors or preneoplastic lesions in rodents. N-Acetylcysteine and other thiols exert antioxidant activity toward superoxide anion, hydrogen peroxide, and singlet oxygen, assessed in bacterial genotoxicity models. In addition, several other mechanisms were shown to contribute to their *antimutagenic* and anticarcinogenic activities, in the extracellular environment and in nontarget or target cells. These mechanisms include blocking of electrophilic metabolites and of direct-acting compounds, either of endogenous or exogenous source, modulation of several xenobiotic-metabolizing pathways, and protection of DNA-dependent nuclear enzymes. Chemoprevention of mutation and cancer by thiols is particularly useful under conditions of reduced glutathione (GSH) depletion due to toxic agents or to cancer-associated viral diseases, such as acquired immunodeficiency syndrome (AIDS) or viral hepatitis B. AB Spermine and spermidine, ubiquitous polyamines present in bacteria

and animal cells, are also involved in cell growth. Since they interact with the double helix, they can stabilize the DNA molecule. Recent evidence of the *antimutagenic* and anticarcinogenic capacity of spermine has focused attention on the mechanism(s) by which such agents can protect cells from induced damages. In the present paper we show the ability of spermine and spermidine to decrease the level of sister chromatid exchanges induced in Chinese hamster ovary cells cultivated in vitro, by treating them with Psoralen + UVA irradiation (able to induce mainly monoadducts and DNA cross-links). Two different mechanisms of polyamine action can be invoked to explain the preservative activity of this class of agents. Author-abstract.

TI Nordihydroguaiaretic acid, an inhibitor of lipoxygenase, also inhibits cytochrome P-450-mediated monooxygenase activity in rat epidermal and hepatic microsomes.

SO Drug-Metab-Dispos-Biol-Fate-Chem. 1991 May-Jun. 19(3). P 620-4.

JT DRUG METABOLISM AND DISPOSITION: THE BIOLOGICAL FATE OF CHEMICALS.

PT JOURNAL-ARTICLE (ART).

AB Nordihydroguaiaretic acid (NDGA), a plant lignan and phenolic antioxidant, is a known lipoxygenase inhibitor. In this study, we investigated the effect of NDGA on rat epidermal and hepatic monooxygenase activity and its interaction with rat hepatic microsomal cytochrome P-450. The addition of NDGA to epidermal microsomes prepared from control and 3-methylcholanthrene (3-MC)-pretreated rats and hepatic microsomal preparations from control, 3-MC-pretreated, and phenobarbital (PB)-pretreated rats resulted in a concentration-dependent inhibition of aryl hydrocarbon hydroxylase (AHH) and 7-ethoxyresorufin O-deethylase (ERD) activities. The 50% inhibitory dose for NDGA ranged from 4.1×10^{-5} to 13.1×10^{-5} M for AHH and ERD activities in these microsomal preparations. The addition of NDGA to hepatic microsomes prepared from PB-pretreated rats resulted in spectral changes characterized by absorbance maxima at 380 nm and minima at 414 nm, typical of type I binding difference spectra. It also showed time- and concentration-dependent inhibition of the binding of carbon monoxide to dithionite or NADPH-reduced cytochrome P-450. We speculate that perhaps hydroxyl groups present in NDGA play an important role in inhibiting the monooxygenase activity and suggest that NDGA may have potential as an *antimutagen* and/or anticarcinogen. Furthermore, caution must be exercised in elucidating the role of lipoxygenase in metabolic pathways based solely on the criterion of inhibition by NDGA. Author-abstract.

TI K-ras mutations in 1,2-dimethylhydrazine-induced colonic tumors:
effects of supplemental dietary calcium and vitamin D deficiency.
SO Cancer-Res. 1991 Aug 15. 51(16). P 4305-9.
JT CANCER RESEARCH.
PT JOURNAL-ARTICLE (ART).
AB Recent studies from our laboratory have demonstrated that dietary
supplemental calcium had no significant effect on the incidence of
1,2-dimethylhydrazine-induced colonic tumors, but did decrease the
number of rats with multiple tumors and reduced tumor size.
Moreover, concomitant vitamin D deficiency appeared to abolish these
protective effects of calcium on colonic tumors in this experimental
model. To date, however, the mechanism(s) involved in these

phenomena remain unclear. In order to address these important issues, 1,2-dimethylhydrazine-induced colonic tumors from animals on control, Ca(2+)-supplemented, vitamin D-sufficient, and Ca(2+)-supplemented, vitamin D-deficient diets were examined for the presence of ras oncogene mutations. DNA was extracted from each of these tumors. Targeted areas of K-ras and H-ras genes were amplified by the polymerase chain reaction and analyzed for point mutations using allele-specific oligonucleotide hybridization and subsequent DNA sequencing. The results of these studies demonstrated that: (a) approximately one-third of 1,2-dimethylhydrazine-induced colonic carcinomas in the control group had K-ras G to A mutations; (b) no mutations, however, were detected in the cancers of the calcium-supplemented group; (c) concomitant vitamin D deficiency abolished the *antimutagenic* effect of dietary calcium supplementation (e.g., approximately one-third of cancers in this group again had detectable K-ras mutations); and (d) no H-ras point mutations were detected in colonic tumors from any group. These findings suggest that alterations in K-ras mutations may be one possible mechanism by which calcium and vitamin D status influence colonic carcinogenesis in this experimental model. TI Evaluation of the mutagenicity of beta-myrcene in mammalian cells in vitro.

SO Environ-Mol-Mutagen. 1991. 18(1). P 28-34.

JT ENVIRONMENTAL AND MOLECULAR MUTAGENESIS.

PT JOURNAL-ARTICLE (ART).

AB The genotoxicity of the terpene beta-myrcene was evaluated in mammalian cells in vitro. Myrcene is the major constituent of oil of bay and hop which are used in the manufacture of alcoholic beverages. Myrcene is also present in lemon grass (*Cymbopogon citratus*), a plant widely used in Brazilian folk medicine. Recently, it was shown that myrcene is a very potent analgesic substance and might be an alternative to the already available analgesic drugs. Myrcene was tested up to 1,000 micrograms/ml (limit of solubility) in the presence and absence of S9-mix and did not induce chromosome aberrations and sister chromatid exchanges (SCEs) in human lymphocytes in vitro. Neither the mitotic index nor the proliferation index was influenced by the myrcene treatment. Myrcene did not cause increased mutation frequencies at the hprt-locus in V79-cells. Tests with and without S9-mix revealed negative results. There was no indication for induced cytotoxicity. However, myrcene reduced the SCE-inducing effect of cyclophosphamide in human lymphocytes in a dose dependent manner and also reduced the toxic and mutagenic effect of cyclophosphamide in V79-cells. Under the same test conditions, SCE induction by ethyl methanesulfonate (EMS) and

benzo`a:pyrene (BP) was not significantly influenced by simultaneous myrcene treatment. The in vitro results show that myrcene is not mutagenic in mammalian cells, but has *antimutagenic* properties. The possibility that myrcene exerts its *antimutagenic* activity by inhibiting certain forms of the cytochrome P-450 isoenzymes required for activation of premutagens and precarcinogenes is discussed. TI *Antimutagenic* and anticarcinogenic effects of betel leaf extract against the tobacco-specific nitrosamine
4-(N-nitrosomethylamino)-1-(3-pyridyl)-1-butanone (NNK).

SO IARC-Sci-Publ. 1991. (105). P 520-4.

JT IARC SCIENTIFIC PUBLICATIONS.

PT JOURNAL-ARTICLE (ART).

AB Earlier studies showed that betel leaf inhibits the mutagenic action of standard mutagens like benzo`a:pyrene and dimethylbenz`a:anthracene. Since tobacco-specific nitrosamines are the major carcinogens present in unburnt forms of tobacco, we studied the effect of an extract of betel leaf on the mutagenic and carcinogenic actions of one of the most potent, 4-(N-nitrosomethylamino)-1-(3-pyridyl)-1-butanone (NNK). Betel-leaf extract and hydroxychavicol suppressed the mutagenicity of NNK in both the Ames and the micronucleus test. In studies in mice, betel-leaf extract reduced the tumorigenic effects of NNK by 25%. Concurrent treatment with the extract also inhibited the decreases in levels of vitamin A in liver and plasma induced by NNK. Betel leaf

thus has protective effects against the mutagenic, carcinogenic and adverse metabolic effects of NNK in mice. Author-abstract.

SO J-Dairy-Sci. 1990 Dec. 73(12). P 3379-84.

JT JOURNAL OF DAIRY SCIENCE.

PT JOURNAL-ARTICLE (ART).

AB *Antimutagenic* activity of acetone or ethylacetate extracts of skim milk fermented by *Streptococcus thermophilus*, *Lactobacillus bulgaricus*, or a combination of both the organisms was studied using *Salmonella typhimurium* (TA 98 and TA 100). Mutagens used were 4-nitroquinoline-N-oxide (a direct-acting mutagen) and 2-aminofluorene (a mutagen requiring S9 activation). Extracts from all fermented milks showed significant (P less than .05) dose response in suppressing the number of revertants caused by NQNO and 2-aminofluorene in both tester strains, whereas extracts from unfermented milk had no effect. Extracts prepared from milk fermented by *L. bulgaricus* plus *S. thermophilus* showed significantly (P less than .05) more *antimutagenic* activity than extracts prepared from milk fermented by *S. thermophilus* alone. Solvent (acetone vs. ethyl acetate) effect was not significant with 4-nitroquinoline-N-oxide as mutagen. However, in the case of 2-aminofluorene, acetone extracts showed significantly (P less than .05) higher *antimutagenic* activity. The results of this and related studies strongly indicate that *antimutagenic* compounds are produced in milk during fermentation by *S. thermophilus* and *L. bulgaricus*. Author-abstract.

TI Organosulfur compounds of garlic modulate mutagenesis, metabolism, and DNA binding of aflatoxin B1.

SO Nutr-Cancer. 1991. 15(2). P 87-95.

JT NUTRITION AND CANCER.

PT JOURNAL-ARTICLE (ART).

AB The effects of two organosulfur compounds of garlic (ajoene and diallyl sulfide) and a crude garlic extract on aflatoxin B1 (AFB1)-induced mutagenesis were determined using rat liver 9,000 g supernatant (S-9) as the activation system and Salmonella typhimurium TA-100 as the tester strain. The effects of these compounds on AFB1 binding to calf thymus DNA were also measured. Metabolites of AFB1 were isolated and analyzed by reverse-phase high-performance liquid chromatography. All these compounds inhibited S-9-dependent mutagenesis induced by AFB1. They also inhibited AFB1 binding to DNA. A significant decrease in organo-soluble metabolites of AFB1 was observed with ajoene and garlic extract. An increase of glucuronide and glutathione conjugates was obtained with garlic extract. The results indicate that garlic compounds tested in this study are *antimutagenic* and, potentially, anticarcinogenic.

TI Modification of DNA repair by human interferons.

SO Acta-Biol-Hung. 1990. 41(1-3). P 187-97.

JT ACTA BIOLOGICA HUNGARICA.

PT JOURNAL-ARTICLE (ART).

AB We have found a new biological function of interferons, namely, their capacity to protect human cells from the action of some physical and

chemical mutagens. To evaluate the protective effect of interferons the following criteria were applied: formation of sister chromatid exchanges (SCE) and chromosomal aberrations (CA), as well as viability of cells and intensity of DNA repair synthesis. Pretreatment of cells with natural interferon decreased the number of sister chromatid exchanges and chromosomal aberrations, induced by different mutagens, and increased the intensity of DNA repair synthesis. This is attributed to the ability of interferon to enhance certain phases of DNA repair. In the case of photomutagenic action of 8-methoxypsoralen (8-MOP) on the lymphocytes, when monoadducts (MA) only, or both monoadducts and interstrand cross-links (ICL) are formed, the *antimutagenic* effect of interferon is exhibited only with respect to ICL. Unlike the natural interferon, the recombinant alpha 2-interferon failed to have any effect on the lymphocytes of clinically healthy donors exposed to gamma-radiation. In the repair- deficient cells (Marfan's syndrome) the protection of natural interferon against the action of 4-nitroquinoline-1'-oxide and gamma- radiation was found to be reduced significantly and that of alpha 2-interferon was not manifested at all. Thus, the capacity of interferons to alter the DNA repair, conceivably, depends on the type of interferon and on the cell genotype. Author-abstract.

by tannic acid and other polyphenols in mouse epidermis in vivo.

SO Cancer-Res. 1991 Jun 1. 51(11). P 2820-5.

JT CANCER RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Naturally occurring plant phenols with *antimutagenic* and anticarcinogenic activities were tested for their abilities to inhibit the ornithine decarboxylase (ODC) response linked to skin tumor promotion by 12-O-tetradecanoylphorbol-13-acetate (TPA). Topical applications of tannic acid (TA) inhibit remarkably and in a dose-dependent manner TPA-induced ODC activity in mouse epidermis in vivo. This inhibitory effect of TA is dependent on the time of its administration relative to TPA. The induction of epidermal ODC activity by 8.5 nmol of TPA is inhibited maximally when 20 μ mol of TA are applied topically to the skin 20 min before the tumor promoter. Gallic acid and several of its derivatives inhibit the ODC response to TPA to a lesser degree than TA. Ellagic acid is the least effective inhibitor tested. TA also inhibits the ODC-inducing activities of several structurally different tumor promoters and the greater ODC responses produced by repeated TPA treatments. The ability of TA to inhibit by 85% the ODC marker of skin tumor promotion suggests that TA and other polyphenols may be effective not only against tumor initiation and complete carcinogenesis but also against the promotion phase of tumorigenesis. TI Modulation by Co(II) of UV-induced DNA repair, mutagenesis and sister-chromatid exchanges in mammalian cells.

SO Mutat-Res. 1991 May. 248(1). P 177-85.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB In bacterial test systems, Co(II) has been shown to be *antimutagenic* in combination with several chemical and physical agents. To investigate whether such modulations also apply to mammalian cells, the effect of Co(II) on UV-induced mutagenesis, sister-chromatid exchanges as well as DNA damage and its removal was determined. Co(II) itself is weakly mutagenic at the HPRT locus and increases the frequency of sister-chromatid exchanges. Additionally, at both endpoints the metal ions enhance the genotoxicity of UV light. To discriminate between an enhancement of DNA damage and an interference with repair processes, the number of pyrimidine cyclobutane dimers was determined by HPLC. While the induction of these DNA lesions is not affected by Co(II), their removal is inhibited at concentrations of 75 μ M Co(II) and higher. Analysis of the kinetics of strand-break induction and closure after UV irradiation by nucleoid sedimentation reveals an accumulation of strand breaks in the presence of Co(II). This indicates that either the polymerization or the ligation step in excision repair is affected. Since similar

interactions with the processing of UV-induced DNA damage have been observed with other carcinogenic and/or mutagenic metal ions, this appears to be a common mechanism of metal genotoxicity.

TI Effect of glutathione on mitomycin C-induced micronuclei in bone marrow erythrocytes of Swiss albino mice.

SO Mutat-Res. 1991 May. 260(1). P 131-5.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB The *antimutagenic* potential of glutathione (GSH) on mitomycin C (MMC)-induced micronuclei was evaluated in Swiss albino mice using the in vivo bone marrow micronucleus test. Six groups of animals were maintained simultaneously. The first group received distilled water only, the second group of animals received 2 mg/kg MMC and the third group was administered 4 doses of GSH, i.e., 20, 40, 80 and 160 mg/kg. The fourth group of animals received GSH and MMC simultaneously. The fifth and sixth groups received a cumulative dose of GSH followed by MMC after 24 h. The fifth group of animals were killed 6 h after the administration of MMC, while the sixth group were killed 24 h after the administration of MMC. The results clearly show a statistically significant increase in micronuclei in MMC-treated animals and also in animals that received GSH followed by MMC. However, there was a decrease in micronuclei in animals that received GSH and MMC simultaneously. The results clearly indicate that GSH exhibits an *antimutagenic* property in the presence of MMC. It is also observed the treatment with GSH prior to MMC does have some protective effect. Author-abstract.

TI `Increase in the fraction of non-repaired mutations in *Escherichia coli* cells, incubated in the absence of glucose after UV-irradiation:.

SO Genetika. 1990 Sep. 26(9). P 1679-81.

JT GENETIKA.

PT JOURNAL-ARTICLE (ART).

AB In *E. coli* WP2 *trpE65* cells irradiated with UV-dose of 11 J/m², the additional small portion of induced Trp⁺ mutations became resistant to photoreactivation or "dark" (excision) repair after a short-termed (10-30 min) postirradiation incubation of bacteria in a minimal medium deprived of glucose and tryptophan. Since protein synthesis could not proceed in those cells because of the lack of energy and tryptophan, the data indicate that an unknown mechanism exists which imparts some mutations with the resistance to *antimutagenic* repair in the absence of the inducible mutagenic system. In the light of this result, one could suggest that the normal process of mutation fixation (that is the loss of sensitivity of mutations to photoreactivation or to excision repair in cells incubated in growth medium after irradiation) should not necessarily be a direct consequence of manifestation of the activity of an inducible mutagenic system. TI Diethyldithiocarbamate suppresses the plant activation of aromatic amines into mutagens by inhibiting tobacco cell peroxidase.

SO Mutat-Res. 1991 Mar. 247(1). P 57-64.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Diethyldithiocarbamate is an *antimutagen* and repressed the activation of promutagens by plant systems. Earlier work implicated the

involvement of tobacco cell (TX1) peroxidases in the plant cell activation of aromatic amines. We now present data that diethyldithiocarbamate represses the activation of 2-aminofluorene and m-phenylenediamine by inhibiting intracellular TX1 peroxidases under in vivo conditions. Concentrations of diethyldithiocarbamate that caused a 50% repression of TX1 cell activation of 2-aminofluorene and m-phenylenediamine also induced a 50% inhibition of TX1 cell peroxidase activity. Diethyldithiocarbamate in a concentration range between 25 and 500 microM directly inhibited peroxidase activity in TX1 cell homogenates in a concentration-dependent manner. Similar results were observed with purified horseradish peroxidase. The kinetics of peroxidase activity were studied in homogenates from control cells and cells treated with 750 microM and 25 mM diethyldithiocarbamate. There was no significant difference among the Km values among the three groups with a mean (+/- standard error) Km of 2.58 +/- 0.23 mM. However, the Vmax differed from 4.02 to 2.12 nmoles tetraguaiacol/min/micrograms protein, in the control and in the 25 mM diethyldithiocarbamate treatment group, respectively. These data indicate that diethyldithiocarbamate is a non-competitive inhibitor of TX1 cell peroxidase. Author-abstract.

JT CARCINOGENESIS.

PT JOURNAL-ARTICLE (ART).

AB Licorice has been used as medicine and as sweetening agent in food products. The major water-soluble constituent of licorice is glycyrrhizin (GL), an oleanane triterpenoid, which is known to be partly hydrolyzed by glucuronidase to its aglycone glycyrrhetic acid (GA) which exists in 18 alpha (alpha-GA) and 18 beta (beta-GA) stereoisomeric forms. In this study alpha-GA and beta-GA were found to inhibit the mutagenicity of benzo(a)pyrene (B(a)P), 2-aminofluorene and aflatoxin B1 in Salmonella typhimurium TA98 and TA100. beta-GA was more effective than alpha-GA as an *antimutagen.* In the two-stage skin tumorigenesis protocol using 7,12-dimethylbenz(a)anthracene (DMBA) as the tumor initiating agent followed by twice weekly applications of 12-O-tetradecanoylphorbol-13-acetate as tumor promoter, pretreatment of SENCAR mice with alpha-GA or beta-GA resulted in significant protection against tumor initiation as well as tumor promotion. As an anti-tumor initiating agent, beta-GA was found to be more

effective than alpha-GA. Similarly, topical application of beta-GA was found to be more effective than alpha-GA in inhibiting the binding of both ³H:B^a:P and ³H:DMBA to epidermal DNA. However, as an anti-tumor promoter, alpha-GA and beta-GA showed comparable effects. Our results suggest that both alpha-GA and beta-GA possess substantial anti-skin tumor initiating and anti-skin tumor promoting activities. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB Riboflavin was shown to inhibit mutagenicity of benzo(a)pyrene and 2-acetylaminofluorene in the presence of S9 liver fractions deriving from B10.A mice as well as from DBA/2 mice and had no influence on mutagenicity of methyl methanesulfonate. The above findings confirm the supposition that antimutagenicity of riboflavin results from its interaction with enzymes responsible for metabolic activation of promutagens. The *antimutagenic* effects of riboflavin were more drastic in the presence of liver fractions from B10.A mice than in the presence of those from DBA/2 mice. Author-abstract.

TI Tea tannin components modify the induction of sister-chromatid exchanges and chromosome aberrations in mutagen-treated cultured mammalian cells and mice.

SO Mutat-Res. 1991 Jan. 259(1). P 79-87.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB The modifying effects of tannin components extracted from green tea and black tea on mutagen-induced SCEs and chromosome aberrations were studied. These tannin components did not affect spontaneous SCEs and chromosome aberrations in cultured Chinese hamster cells. The frequency of SCEs and chromosome aberrations induced by mitomycin C (MMC) or UV was enhanced by the posttreatment with tea tannin components. When cells were post-treated with tea tannin components in the presence of metabolic enzymes of rat liver (S9 mix), the modifying effects on the induction of SCEs and chromosome aberrations by mutagens were complicated. MMC- and UV-induced SCEs and chromosome aberrations were suppressed by the posttreatment with tea tannin components at low concentrations (less than or equal to 6.7 micrograms/ml) with S9 mix. At a high concentration of tea tannin

components (20 micrograms/ml) with S9 mix, a co-mutagenic effect was observed. The modifying effects of tea tannin components were shown to occur in the G1 phase of the cell cycle. In cells from a patient with xeroderma pigmentosum (XP) and a normal human embryo, MMC-induced SCEs were suppressed by the posttreatment with tea tannin components in the presence of S9 mix, and enhanced in the absence of S9 mix. On the other hand, tea tannin components modified SCE frequencies in UV-irradiated normal human cells but not in UV-irradiated XP cells. Our results suggested that tea tannin components themselves inhibited DNA-excision repair and resulted in a co-mutagenic effect, while in the presence of S9 mix metabolites of tea tannin components promoted DNA-excision repair activity and resulted in an *antimutagenic* effect. MMC-induced chromosome aberrations in mouse bone marrow cells were suppressed by the pretreatment with green tea and black tea tannin mixture. Author-abstract.

AB Thirty women participated in a double-blind randomized cross-over trial of the efficacy of a natural product, the powdered root of ginger (*Zingiber officinale*), and placebo in hyperemesis gravidarum. Three patients had to be withdrawn. Each woman swallowed capsules containing either 250 mg ginger or lactose q.i.d. during the first 4 days of the treatment period. Interrupted by a 2 days wash-out period the alternative medication was given in the second 4-day period. The severity and relief of symptoms before and after each period were evaluated by two scoring systems. The scores were used for statistical analyses of possible differences. Subjectively assessed, 19 women (70.4%) stated preference to the period in which ginger, as was later disclosed, had been given ($P = 0.003$). More

objectively assessed by relief scores a significantly greater relief of the symptoms was found after ginger treatment compared to placebo ($P = 0.035$). No side effects were observed. The possible mutagenic and *antimutagenic* characters of ginger reported in a study of *E. coli* have not been evaluated with respect to any significance in humans. Powdered root of ginger in daily doses of 1 g during 4 days was better than placebo in diminishing or eliminating the symptoms of hyperemesis gravidarum. Author-abstract.

JT MUTATION RESEARCH.
PT JOURNAL-ARTICLE (ART).
AB The effect of simultaneous pretreatment with vitamins C and E on the toxicity and mutagenicity of K2Cr2O7 in rats and guinea pigs was evaluated. Dietary pretreatment of Cr(VI)-intoxicated rats with ascorbic acid or alpha-tocopherol normalized vitamin C levels in lungs but not in kidneys. The synergistic preventive effect of both vitamins was confirmed in the production of lipoperoxides in Cr(VI)-intoxicated rats. Simultaneous administration of vitamins C and E in guinea pigs prevented the decrease of vitamin C levels provoked by the oxidative effects of Cr(VI). The results of the micronucleus test in bone marrow showed that it was vitamin C that caused the *antimutagenic* effect against bichromate, in both rats and guinea pigs. The effect of vitamin E was demonstrated only in an increase of the ratio of NCE to PCE, i.e., in a decrease of the cytotoxic but not the mutagenic effects of hexavalent chromium.

SO Mutat-Res. 1991 Jan. 262(1). P 25-30.
JT MUTATION RESEARCH.
PT JOURNAL-ARTICLE (ART).
AB Studies with the arabinose-resistant Salmonella forward mutation assay system were performed to determine the *antimutagenic* activity of chlorophyllin against the mutagenic activity of aflatoxin B1 (AFB1), 2-aminoanthracene (2AA), benzo`a:pyrene (BaP), N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) and solvent extracts of coal dust (CD), diesel emission particles (DE), airborne particles (AP), tobacco snuff (TS), black pepper (BP) and red wine (RW). Various concentrations of each chemical and complex mixture extract were assayed for mutagenic activity with and/or without S9 in a preincubation test. One concentration of each chemical and complex mixture extract was then tested with various concentrations of chlorophyllin. Results showed that chlorophyllin, at concentrations of 2.5 mg/plate or less, completely or almost completely inhibited the mutagenicity of 2AA, AFB1, BaP, MNNG and solvent extracts of CD, DE and RW. With concentrations from 1.25 to 5 mg/plate, chlorophyllin inhibited over 50% of the mutagenicity of AP, TS and BP extracts. These results further substantiate the *antimutagenic* efficacy of chlorophyllin against chemicals and complex mixtures. Author-abstract.

JT MUTATION RESEARCH.
PT JOURNAL-ARTICLE (ART).
AB A methanol extract of air-borne particulates collected in a suburban area of Okayama City showed not only mutagenicity but also antimutagenicity in the Ames test. Thus, when the mutagenicity of this preparation in Salmonella typhimurium TA98 (with metabolic activation) was measured, we observed that the dose response reached a plateau at 27 m3 air equivalent of the particulate, showing approximately equal numbers of revertants in the dose range 27-270 m3 equivalent. This plateau formation was not seen in the dose response of a blue-cotton extract of this preparation: the extract gave a linearly increasing dose response up to 270 m3 equivalent. This finding suggests that some factors that inhibit the mutagenicity were present in this methanol extract and that these inhibitors were not adsorbable to blue cotton, an adsorbent selective for compounds having 3 or more fused rings. From the portion unadsorbed to blue cotton, we isolated the *antimutagenic* factors and identified them as long-chain fatty acids: palmitic, stearic, oleic and linoleic acids.

Analysis of several samples, including those from other parts of Japan, has suggested that these *antimutagenic* fatty acids are ubiquitous in air-borne particulates. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB After thawing cells, previously cryopreserved in the presence of dimethyl sulfoxide (DMSO), a decrease in their viability and increase in unscheduled DNA synthesis was observed. In 7 days, these parameters restored to the control level. Cryopreservation without DMSO resulted in the decrease in both cell viability and replicative and unscheduled DNA synthesis. In 14 days, these characteristics

were seen to return to the normal level. Cryopreservation of cells without DMSO and their preservation in liquid nitrogen induced the frequency of chromosomal aberrations, mostly chromosomal breaks. The frequency of chromosomal aberrations increased with the duration of cell preservation in liquid nitrogen. The normal level was achieved following 7 days after cell thawing. Cells treated with DMSO only (without cryopreservation) display an increased number of chromosomal and chromatid breaks and translocations. Nonrandom distribution of chromosomal aberrations was observed, with particular chromosomes being involved in the appearance of dicentrics and translocations. The data obtained indicate that cryoprotective activity of DMSO is probably associated with the cell repair systems. The detected *antimutagenic* and mutagenic activity of DMSO may presumably reflect various conditions for its interaction with cells (with or without cryopreservation), as well as it may be specific for the muntjac cell line used in the present work. TI Preventive action of thioethers towards in vitro DNA binding and mutagenesis in E. coli K12 by alkylating agents.

SO Mutat-Res. 1990 Oct. 245(2). P 67-74.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Thioethers are effective scavengers of electrophilic metabolites derived from the hepatocarcinogen N-hydroxy-2-acetylaminofluorene (van den Goorbergh et al., 1987). In this study 2 of these thioethers, 4-(methylthio)benzoic acid (MTB) and its methylester, methyl 4-(methylthio)benzoate (MMTB), have been tested for their ability to prevent in vitro DNA binding and mutation induction in E. coli K12 by the direct alkylating agents ethylnitrosourea (ENU), methylnitrosourea (MNU), ethyl methanesulfonate (EMS) and methyl methanesulfonate (MMS). In addition to MTB and MMTB, the thioether L-methionine (Met), and the thiols glutathione (GSH) and L-cysteine (Cys) were included for reasons of comparison. MTB was able to (partially) prevent DNA binding and mutation induction by ENU. However, this thioether was ineffective with EMS. DNA binding and mutagenesis by EMS were (partially) prevented by GSH and Cys, while these thiols could not prevent DNA binding and mutation induction by ENU. MMTB was unable to prevent mutation induction by these ethylating agents. With the methylating agents, similar effects of MTB were observed: MTB effectively prevented mutation induction by MNU while it was much less effective towards MMS. GSH and Cys were comparably effective as *antimutagenic* agents towards both methylating agents. Met was unable to prevent either DNA binding or mutation induction by these agents. Taken together, the results show that aromatic thioethers are able to trap genotoxic electrophiles derived from the nitrosoureas ENU and MNU, and may therefore act as potential anticarcinogens towards these agents, which are only poorly detoxified by GSH. officinalis L., C. arvensis L. and Hedera helix L.
SO Mutagenesis. 1990 Jul. 5(4). P 327-31.
JT MUTAGENESIS.
PT JOURNAL-ARTICLE (ART).
AB Thirteen saponins were isolated and identified from Calendula
officinalis, C. arvensis and Hedera helix. Mutagenic and
antimutagenic activities of these products were investigated using a
modified liquid incubation technique of the Salmonella/microsomal
assay. The Salmonella tester strain TA98 +/- S9 mix was used.
Screening of the *antimutagenic* activity was performed with a known
promutagen: benzo-`a:pyrene (BaP) and a mutagenic urine concentrate
from a smoker (SU). *Antimutagenic* activities were also compared with
the activity of chlorophyllin. All the saponins were found to be
non-toxic and non-mutagenic for doses of 400 micrograms.
Chlorophyllin inhibited the mutagenic activities of BaP (1 microgram)
and SU (5 microliters) in a dose-dependent manner. The four saponins
from C. arvensis and the three saponins from H. helix showed
antimutagenic activity against BaP (1 microgram) and SU (5
microliters) with a dose-response relationship. The possible
mechanism of the *antimutagenic* activity of saponins is discussed.

TI Mechanism of the in vitro *antimutagenic* action of retinol.

SO Mutagenesis. 1990 May. 5(3). P 257-62.

JT MUTAGENESIS.

PT JOURNAL-ARTICLE (ART).

AB The *antimutagenic* action of retinoids against three amino-imidazoazaarene pre-carcinogens, i.e. 2-amino-3-methylimidazo(4,5-f)quinoline (IQ), 2-amino-3,4-dimethylimidazo(4,5-f)quinoline (MeIQ) and 2-amino-3,8-dimethylimidazo(4,5-f)quinoxaline (MeIQx), was

investigated using the Ames test and hepatic activation systems derived from rats pretreated with Aroclor 1254. Both retinol and retinal, when incorporated into the S9 activation system, gave rise to a concentration-dependent decrease in the mutagenicity of all three mutagens, retinol being generally the more effective. Retinol suppressed the mutagenic activity of IQ even when isolated microsomes were used as activation systems. Moreover, retinol gave rise to a concentration-dependent inhibition of the microsomal dealkylations of pentoxy- and benzyloxy- and, especially, ethoxy-resorufin, but had no effect on the NADPH-dependent reduction of cytochrome c. Exposure of the bacteria to retinol with subsequent removal of the vitamin did not influence the mutagenicity of IQ. It is concluded that retinoids suppress the mutagenicity of aminoimidazoazaarenes and this is achieved through inhibition of their cytochrome P450-dependent metabolic activation. Retinol is a non-selective in vitro inhibitor of the hepatic cytochrome P450-dependent mixed function oxidase system as predicted by a computer graphic analysis of its molecular shape. TI *Antimutagens* from *Momordica charantia*.

SO Mutat-Res. 1990 Jun. 230(2). P 121-6.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB The *antimutagenic* principle of the green fruits of *Momordica charantia* was shown by the micronucleus test to be an intractable mixture of novel acylglucosylsterols. The *antimutagens* were extracted from the green fruits with ethanol and isolated from the bioactive petroleum ether and carbon tetrachloride extracts by

repeated and sequential flash column chromatography. The major component of the mixture is 3-O-`6'-O-palmitoyl-beta-D-glucosyl-stigmasta-5,25(27)-dien and the minor component is the stearyl derivative (Guevara, 1989). At a dosage range in mice of 50-12.5 micrograms extract/g, the mixture reduced by about 80% the number of micronucleated polychromatic erythrocytes induced by the well-known mutagen mitomycin C. Structure-activity correlation studies suggested that the *antimutagenic* activity may reside in the peculiar lipid-like structure of the acylglucosylsterols. Ingestion of these compounds may result in their absorption in the plasma membrane lipid bilayer which could adversely affect the membrane permeability towards mitomycin C and disrupt the cellular activity of the latter. Author-abstract.

TI 2,`3:tert-butyl-4-hydroxyanisole does not reduce SCE induction by benzo(a) pyrene in bone marrow cells of C57BL/6 mice.

SO Environ-Mol-Mutagen. 1990. 16(1). P 26-31.

JT ENVIRONMENTAL AND MOLECULAR MUTAGENESIS.

PT JOURNAL-ARTICLE (ART).

AB Recently, a number of publications have suggested that bone marrow cytogenetics may be used to detect anticarcinogenic or *antimutagenic* activity. In this work, 0.75% 2,`3:-tert-butyl-4-hydroxyanisole (BHA), fed in the diet for 2 weeks, was tested for its ability to reduce the frequency of benzo(a)pyrene (BP)-induced SCE in mouse bone marrow. C57BL/6 male mice, were injected i.p. with BP at 0, 33, 67, and 100 mg/kg body weight. The mean SCE/chromosome +/- s.e.m. for animals on control diet was 0 mg/kg, 0.108 +/- 0.005; 33 mg/kg, 0.225 +/- 0.011; 67 mg/kg, 0.289 +/- 0.012; 100 mg/kg, 0.311 +/- 0.013. The mean SCE/chromosome +/- s.e.m. for animals on the 0.75% BHA diet was 0 mg/kg, 0.105 +/- 0.006; 33 mg/kg, 0.224 +/- 0.009; 67 mg/kg, 0.262 +/- 0.013; 100 mg/kg, 0.326 +/- 0.012. There are no significant differences between animals on the control and BHA diets. Excretion of BP in urine over a 72 hr time period was significantly increased in animals on the BHA diet, at both low and high doses. Water-soluble metabolites accounted for all of this increase. It appears that bone marrow is not a good model for the gastrointestinal tract, and that short-term assays for anticarcinogens or *antimutagens* are more likely to be predictive if they are done in the target organs. PT JOURNAL-ARTICLE (ART).

AB The influence of the oxicams, a special group of non-steroidal anti-inflammatory drugs, to the sister chromatid exchange (SCE) was determined on human lymphocytes in vitro and in vivo. The analysis of SCE is a sensitive parameter indicating chromosomal damage. The cytogenetic examinations of Lornoxicam, Tenoxicam, and Piroxicam in vitro showed no influence on the SCE frequencies in therapeutic dosages. With addition of mitomycin C (MMC) to the cultures (a method which simulates an additional genotoxic stress) we found significant higher SCE rates in connection with the oxicams than in controls without an oxicam. A 14-day treatment with Tenoxicam and Lornoxicam changed the spontaneous SCE rates in vivo; Piroxicam did not. The raised SCE levels could indicate an *antimutagenic* effect of the oxicams if the repair of DNA damages is transferred to a more perfect pathway; however by an overloading of the repair, due to additional genotoxic factors (such as cytostatics, cigarette smoking, x-ray exposure) therapy with oxicams could point out a genotoxic risk. SO Cancer-Lett. 1989 Sep 15. 47(1-2). P 37-44.

JT CANCER LETTERS.

PT JOURNAL-ARTICLE (ART).

AB Tannic acid, a naturally occurring plant phenol, inhibited rat liver S9 mediated mutagenesis of benzo`a:pyrene in Salmonella typhimurium by 32-77% at concentrations of 5-50 micrograms/mutagenesis plate. Tannic acid (10-40 microM) had no affect on the formation of organosoluble metabolites of benzo`a:pyrene or of its water-soluble conjugates. It did, however, inhibit benzo`a:pyrene (B`a:P) metabolite binding to calf thymus DNA by 40% at a concentration of 40 microM and inhibited benzo`a:pyrene 7,8-dihydrodiol-9,10-epoxide (BPDE): deoxyguanosine adduct formation in calf thymus DNA by 12-54% at concentrations of 10-40 microM. These results suggest that the *antimutagenic* effect of tannic acid and inhibition of B`a:P metabolite binding to DNA is by a previously described scavenging mechanism and/or by a DNA-affinity binding mechanism that prevents BPDE interaction with DNA as previously described for ellagic acid. TI In vivo anticlastogenic and *antimutagenic* effects of tannic acid in mice.

SO Mutat-Res. 1990 May. 244(1). P 43-7.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB The anticlastogenic effect of tannic acid was studied in vivo in the mouse micronucleus test. The frequencies of micronuclei induced by mitomycin C, ethyl nitrosourea (ENU) or 4-nitroquinoline 1-oxide in mouse bone marrow cells were decreased by the oral administration of tannic acid 6 h before the mutagen injection. The observed suppressing effect was not a reflection of a delay in the formation of micronuclei by the cytotoxic effect of tannic acid. The *antimutagenic* effect of tannic acid was also investigated in vivo in the mouse spot test using male PW and female C57BL/10 mice. Tannic acid was given orally to pregnant females 6 h before the intraperitoneal injection of ENU on the 10th day of pregnancy. The frequency of pups with recessive color spots induced by ENU was decreased by the administration of tannic acid. The observed decrease was not due to toxic effects on the embryo. These results indicate that tannic acid acts as an anticlastogen and *antimutagen* in vivo. Author-abstract.

JT ENVIRONMENTAL AND MOLECULAR MUTAGENESIS.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-ACADEMIC (RAC).

AB In this review recent publications are cited for a number of *antimutagens.* The molecules surveyed are potential or proven "desmutagens" or "interceptors." These are biologically prevalent or synthetic molecules that are most often small metabolites proficient in binding to, or reacting with, mutagenic chemicals and free radicals. Many of this class of "blocking agents" are "soft" and "hard" nucleophiles with consequently varying abilities to react with particular classes of electrophiles, the major classes of direct-acting mutagens. Although they serve as a first line of defense against mutagens and carcinogens, many interceptor molecules are under-investigated with regard to their spectra of activity and their possible relevance to prophylaxis or treatment of human disease states. PT JOURNAL-ARTICLE (ART).
AB Procedures have been developed which enable the study of *antimutagenic* specificity of certain *antimutagenic* chemicals against chemical mutagens/carcinogens. Modifications of the Ames Salmonella assay, the Bacillus subtilis rec assay of Kada and co-workers, and the Luria-Delbruck fluctuation test, along with procedures we have developed utilizing E. coli K12 strain ND160 developed by Dworkin, all are employed in these studies. Using these procedures, a number of naturally-occurring compounds and/or their derivatives have been shown to produce *antimutagenic* specificity either against changes at different specific genetic loci or against activity of specific chemical mutagens such as nitrofurazone, ethyl methanesulfonate, or caffeine. Compounds that demonstrate this activity include cinnamaldehyde, chlorophyllin, an extract of Glycyrrhiza glabra, spermine, and mixtures of guanosine and cytidine. The data demonstrate that some *antimutagens* act specifically against spontaneous mutations, while others inhibit the development of chemically-induced mutations at specific loci. These results have potential application to the prevention of chemical toxicological damage. Author-abstract.

PT JOURNAL-ARTICLE (ART).
AB Crude extracts and partially purified as well as purified fractions were prepared from three Thai medicinal plants, namely, Acanthus ebracteatus Vahl, Plumbago indica Linn, and Rhinacanthus nasutus Kurz, and then tested for their mutagenic and *antimutagenic* potentials using the Salmonella/microsome mutagenicity test. All fractions tested were not mutagenic toward either strain TA98 or TA100 whether tested in the presence or absence of S-9 mix. Interestingly, however, various fractions--especially those extracted by organic solvents such as petroleum ether, hexane, and chloroform, as well as some purified compounds from these plants--could strongly inhibit the mutagenicity of aflatoxin B1 (AFB1), an indirect mutagen, when tested in the presence of S-9 mix but not that of 2-(2-furyl)-3-(5-nitro-2-furyl)acrylamide (AF-2), which does not require metabolic activation for its mutagenicity. Furthermore,

these fractions could markedly inhibit the activity of rat liver aniline hydroxylase, which is one of the cytochrome-P450-mediated reactions. These results therefore suggest that these Thai medicinal plants contain an *antimutagen(s)* which inhibits chemical mutagenesis by inhibiting the enzyme activities necessary for activation of indirect mutagens/carcinogens. Identification as well as anticarcinogenicity of purified compounds of these plants are being investigated in our laboratory. Author-abstract.

PT JOURNAL-ARTICLE (ART).
AB Aqueous salt solutions containing NaCl, KCl, MgCl₂, Na₂SO₄, CaCl₂, NH₄Cl, or sodium saccharin are mutagenic in yeast when logarithmic growth of cells is interrupted by exposure to a 0.5-2.0 M salt solution. Stationary-phase cells are not mutated by this treatment. When placed in an enriched medium with the salt, the stationary-phase cells grow after a prolonged lag period. The compounds tested (NaCl, KCl, and sodium saccharin), under conditions in which growth in medium can take place, exhibit an *antimutagenic* response as measured by the compartmentalization test. The *antimutagenic* action of salt solutions in yeast is concentration-dependent. Unlike the mutagenic action of these compounds, which approximates an osmolality-dependent response, the *antimutagenic* action seems to be correlated with toxicity as measured by growth rate reduction at increasing concentrations of the compounds. For example, sodium saccharin and NaCl exhibit almost identical osmolalities; however, 0.3 M sodium saccharin reduces the growth rate much more than does 0.3 M NaCl. At these same molar concentrations, the spontaneous mutation rate for histidine prototrophy is, for the control, 6.2×10^{-8} mutations/cell/-generation, 3.5×10^{-8} with 0.3 M NaCl, and 1.7×10^{-8} with 0.3 M sodium saccharin. JT BASIC LIFE SCIENCES.
PT JOURNAL-ARTICLE (ART).
AB Cultured mammalian cell systems are useful for examining the quantitative effects of mutagens and *antimutagens* on cell survival and gene mutations and the mechanisms of the interaction of two chemicals in the process of mutation induction. In the present article, the *antimutagenic* effects of vitamins C, E, and A, and derivatives of vitamin C on EMS-induced 6TG-resistant mutations in Chinese hamster V79 cells were examined. Vitamin C was most effective in inhibiting EMS-induced cytotoxicity and 6TG-resistant

mutations. In the presence of vitamin C at a concentration of 100 micrograms/ml, EMS-induced mutations were reduced to about one-third or one-fourth of those in control cultures treated with EMS alone. Dehydro-vitamin C and iso-vitamin C also inhibited EMS-induced mutations to about one-half or one-third of the control level. The fact that vitamin C was effective in reducing EMS-induced mutations when EMS was previously incubated together with vitamin C for 3 hr suggests that vitamin C may react directly with EMS as a desmutagen and thus inactivate its mutation-inducing activity in Chinese hamster V79 cells. Vitamin E had an additive cytotoxic effect on EMS-induced cytotoxicity. This vitamin enhanced the frequencies of 6TG-resistant mutations induced by EMS. Pretreatment with vitamin E before treatment with EMS resulted in no detectable effect in modifying the EMS-induced mutations. On the contrary, vitamin A markedly enhanced EMS-induced mutation frequencies. Author-abstract.

TI Suppressing effect of *antimutagenic* flavorings on chromosome aberrations induced by UV-light or X-rays in cultured Chinese hamster cells.

SO Mutat-Res. 1990 Mar. 229(1). P 1-10.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Chromosome aberrations induced by UV-light or X-rays were suppressed by the post-treatment with *antimutagenic* flavorings, such as anisaldehyde, cinnamaldehyde, coumarin, and vanillin. UV- or X-ray-irradiated surviving cells increased in the presence of each flavoring. X-ray-induced breakage-type and exchange-type chromosome aberrations were suppressed by the vanillin treatment in the G1 phase of the cell cycle and a greater decrease in the number of X-ray-induced chromosome aberrations during G1 holding was observed in the presence of vanillin. Furthermore, a greater decrease in the number of X-ray-induced DNA single-strand breaks was observed in the presence of vanillin. Treatment with vanillin in the G2 phase suppressed UV- and X-ray-induced breakage-type but not exchange-type chromosome aberrations. The suppression of breakage-type aberrations was assumed to be due to a modification of the capability of the post-replicative repair of DNA double-strand breaks. These G1- and G2-dependent anticlastogenic effects were not observed in the presence of 2',3'-dideoxythymidine, an inhibitor of DNA polymerase beta. Based on these results, the anticlastogenic effect of vanillin was considered to be due to the promotion of the DNA rejoining process in which DNA polymerase beta acts. Author-abstract.

spot formations in mice by vanillin.

SO Mutat-Res. 1990 Feb. 243(2). P 151-8.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB The *antimutagenic* effects of vanillin, anisaldehyde, cinnamaldehyde
and coumarin were investigated in cultured Chinese hamster V79 cells
in vitro. The frequencies of 6-TG-resistant mutations induced by UV
or X-rays were decreased by treatment with each compound during the
expression time. These decreases were not due to cytotoxic effects
on cellular growth or killing effects on damaged cells. The
antimutagenic effect of vanillin was also investigated in vivo in the
mouse spot test using male PW and female C57BL/10 mice. Female mice
were injected intraperitoneally with ethylnitrosourea (ENU) on the
10th day of pregnancy and received 3 successive oral administrations
of vanillin. Administration of vanillin decreased the ENU-induced
frequency of recessive carrier pups. These results indicate that
vanillin acts as an *antimutagen* in mammalian cells both in vitro and
in vivo. Author-abstract.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).

AB The concept of activity profile listings and plots, already applied successfully to the display of mutagenicity data, has been modified for application to antimutagenicity data. The activity profiles are bar graphs that have been organized in two general ways: for *antimutagens* that have been tested in combination with a given mutagen and for mutagens that have been tested in combination with a given *antimutagen.* Doses from both the mutagen and the *antimutagen* are displayed and plotted together with results on enhancement or inhibition of mutagenic activity. The short-term tests that have been used extensively to identify mutagens and potential carcinogens are increasingly being used to identify *antimutagens* and potential anticarcinogens. Three model mutagens, N-methyl-N'-nitro-N-nitrosoguanidine, aflatoxin B1 and benzo`a:pyrene, and 4 model *antimutagens,* butylated hydroxyanisole, butylated hydroxytoluene, glutathione and disulfiram, were selected from the data surveyed in the published literature. It is not clear at the present time whether the inhibition of carcinogen-induced mutation is a good indicator of anticarcinogenic properties, and further research is needed. Nevertheless, the activity profiles are useful for the assessment of the available antimutagenesis data by providing rapid visualization of considerable dose information and experimental results. JT GENETIKA.

PT JOURNAL-ARTICLE (ART).

AB On the basis of the SOS-chromotest which was developed by the authors earlier, the minimum time required for expression of the SOS-response is shown to be 15 min, the maximum being recorded 2 h later. An assay of induction of the SOS-response to the mutagens which act on DNA via various mechanisms (e. g., UV-irradiation, mitomycin C, nalidixic acid, nitroso-methylurea and acridine orange) revealed that all the mutagens under study caused induction of the SOS-response. Analysis of efficiency of SOS induction under the action of a mixture of formaldehyde with various amino acids has shown that arginine, asparagine and, especially, cysteine decrease the level of the SOS-response induction. This fact suggests an opportunity for using the SOS-chromotest not only to identify the mutagens and cancerogens, but also to screen the agents for their *antimutagenic* activity. The study of the SOS-response in the cells which are deficient in genes for repair and recombination has shown that induction is significantly suppressed in the mutants *recA*, *lexA* and *recF*; it is not modified in *sbcB* mutants and is significantly increased in the mutant lines *recBC*, *uvrB* and, particularly, in the double mutant *recBCsbcB*. SO Cancer-Res. 1989 Dec 1. 49(23). P 6600-4.

JT CANCER RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Taurine (2-aminoethanesulfonic acid) was evaluated as an *antimutagen* in the Ames Salmonella tester strain assay. Taurine inhibited mutagenesis by doxorubicin (-74%), bleomycin (-55%), mitomycin C (-56%), and 2-aminofluorene (-52%), but not danthrone or benzo(a)pyrene, in strain TA102. In strain TA98, doxorubicin mutagenicity, but not that of 2-aminofluorene or benzo(a)pyrene, was inhibited by taurine. N-Methyl-N'-nitro-N-nitrosoguanidine (-73%), but not dexamethasone, mutagenicity was inhibited by taurine in strain TA100. Taurine inhibited those mutagens against which it was effective in a dose-related fashion. Taurine was more effective in inhibiting doxorubicin mutagenicity in strain TA102 than its analogues hypotaurine, beta-alanine, and guanidinoethanesulfonic acid or alanine or glycine. The observed inhibition may indicate a role for taurine in modulating the activity of oxidant species.

JT ANTICANCER RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Chlorophyllin (CHL) was tested for its effect on 1,2-dimethylhydrazine (DMH)-induced nuclear aberrations in rat colonic epithelium. Rats were given water containing CHL (1.5 mM) and food ad libitum. After 5 wks on this dietary regimen, the rats were given a single intraperitoneal injection of DMH (20 mg DMH base/kg body weight). The rats were sacrificed 18 hours later and their colons were removed. Ten consecutive crypts from the proximal and distal portion of each specimen were scored for nuclear aberrations and the karyorrhectic index (KI) was determined. Rats receiving CHL + DMH had significantly fewer nuclear aberrations (lower KI) in the colonic epithelium than rats given DMH alone. This implies that CHL, a known *antimutagen,* may have anticarcinogenic properties as well. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB The 1,4-dihydropyridine derivative

2,6-dimethyl-3,5-diethoxycarbonyl-4-(Na carboxylate)-1,4-dihydropyridine (1,4-DHP) was studied for *antimutagenic* effects in the dominant lethal test and in the sex-linked recessive lethal test of *Drosophila melanogaster*. The observed effects were compared with those of the radioprotectors cysteine and cysteamine and with those of the phenolic antioxidant butylated hydroxytoluene (BHT). In a wide range of concentrations, including low ones, 1,4-DHP reduces the frequency of EMS-induced genetic damage (point mutations and chromosome breakage). A reduction of the mutation rate induced by EMS in adults could be observed independently of the developmental stages (larvae or imago) pretreated with 1,4-DHP. The protective effect of this new *antimutagen* against the alkylating agent depended on both the 1,4-DHP dose and the level of the EMS-induced mutation rate. The effect of 1,4-DHP was more pronounced than that of the studied radioprotectors. It is concluded that dihydropyridine-type compounds are able to protect eukaryote germs cells from genetic damage produced by direct-acting mutagens such as EMS. Author-abstract.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB 2-Hydroxy-3-methoxybenzaldehyde (omicron-vanillin), the *antimutagenic* effect of which has been reported on mutagenesis induced by 4-nitroquinoline 1-oxide (4NQO) in *Escherichia coli* WP2s, enhanced N-methyl-N'-nitro-N-nitrosoguanidine (MNNG)-induced mutagenesis in the same strain. A remarkable enhancement of mutagenesis provoked by N-methyl-N-nitrosourea (MNU) was also observed by the addition of omicron-vanillin. No enhancing effect was observed on mutagenesis induced by other mutagens such as methyl methanesulfonate (MMS), dimethylsulfate, N-ethyl-N'-nitro-N-nitrosoguanidine (ENNG), N-ethyl-N-nitrosourea (ENU), ethyl methanesulfonate, diethylsulfate, 4NQO and furofuramide (AF-2). On the contrary, omicron-vanillin greatly suppressed AF-2- and 4NQO-induced mutagenesis and showed a slight suppressing effect against mutagenesis induced by MMS, ENNG and ENU. One possible explanation for the enhancing effect of omicron-vanillin on the mutagenesis induced by MNNG or MNU in *E. coli* WP2s may be inhibition of an inducible adaptive response. Among 7 derivatives of omicron-vanillin, 2-hydroxy-3-ethoxy-benzaldehyde, omicron-hydroxybenzaldehyde and m-methoxybenzaldehyde showed an enhancing effect on MNNG-induced mutagenesis. JT CELL BIOLOGY AND TOXICOLOGY.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).

AB By definition, short-term tests (STTs) for genetic toxicity detect genotoxic agents, not carcinogens specifically. However, there is sufficient evidence, based on mechanistic considerations alone, to say that genotoxic agents are potential carcinogens. STTs have high statistical power, are almost always replicated, can be performed rather easily under various sets of experimental conditions, are relatively inexpensive, and detect a variety of endpoints relevant to carcinogenesis. In addition, several STTs have shown considerable utility in evaluating the genotoxic effects of real-world, environmental complex mixtures as well as the *antimutagenic* effects of various pure compounds and complex mixtures. STTs are likely to continue to be refined, resulting in STTs that are increasingly more relevant to human mutation and disease. Their utility should not be judged solely against the questionable standard of a rodent carcinogenicity assay. Author-abstract. 70 Refs.

SO Mutat-Res. 1989 Aug. 213(2). P 135-40.
JT MUTATION RESEARCH.
PT JOURNAL-ARTICLE (ART).
AB An inhibitor of uracil-DNA glycosylase, uracil, induces an increase
in the size of pulse-labelled DNA fragments in human cells in vivo
suggesting that dUMP incorporation into DNA and uracil-DNA
glycosylase contribute to the small size of pulse-labelled DNA. It
is also shown that inhibition of DNA methylation in vivo by ethionine
and 5-azacytidine induces a decrease in the size of pulse-labelled
DNA, and the effect is partially suppressed by uracil. In vitro
experiments with purified uracil-DNA glycosylase from human placenta
show that DNA hypermethylation inhibits the enzyme. The data make it
possible to explain the *antimutagenic* effect of ethionine in
mammalian cells: by stimulation of the repair of DNA containing
incorporated uracil on the basis of the hypothesis that DNA-uracil
repair stimulates mismatch correction leading to preferential
excision of misincorporated nucleotides from daughter DNA strands.

PT JOURNAL-ARTICLE (ART).
AB The anti-psoriatic compound anthralin (dithranol, cignolin) was
determined to exhibit a strong cytostatic activity on HeLa-Koln
cells; an ED50 concentration of 1.2 microM was determined for the
cells. These growth-inhibition data were confirmed by
thymidine-uptake experiments. The drug anthralin was determined to
be neither direct a mutagen nor a premutagen in the Ames test using
Salmonella typhimurium strain TA 100 (anthralin-concentration = 5
microM). Moreover, this compound was a strong inhibitor of
benzo(a)pyrene monooxygenase, an enzyme which causes the metabolic
conversion of premutagens to mutagens. These data demonstrate
anthralin to be an antipsoriatic compound devoid of mutagenic
property in vitro with regard to base-pair substitutions and provided
at least with some *antimutagenic* potential. Author-abstract.

SO Mutat-Res. 1989 Jul. 223(3). P 273-85.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB For centuries green tea has been a widely consumed beverage throughout the world. It is known to contain a number of pharmacologically active compounds. In this study water extracts of green tea (WEGT) and their major constituents, green tea polyphenols (GTP), were examined for *antimutagenic* activity. WEGT and GTP were found to significantly inhibit the reverse mutation induced by benzo`alpha:pyrene (BP), aflatoxin B1 (AFB1), 2-aminofluorene, and methanol extracts of coal tar pitch in Salmonella typhimurium TA100 and/or TA98 in the presence of a rat-liver microsomal activation system. GTP also inhibited gene forward mutation in V79 cells treated with AFB1 and BP, and also decreased the frequency of sister-chromatid exchanges and chromosomal aberrations in V79 cells treated with AFB1. The addition of GTP during and after nitrosation of methylurea resulted in a dose-dependent inhibition of mutagenicity. Studies to define the mechanism of the *antimutagenic* activity of GTP suggest that it may affect carcinogen metabolism, DNA adduct formation, the interaction of ultimate carcinogen or the scavenging of free radicals. PT JOURNAL-ARTICLE (ART).

AB Experiments with Salmonella tester strains indicated that aqueous garlic extract possesses *antimutagenic* properties toward ionizing radiation, peroxides, adriamycin, and N-methyl-N'-nitro-nitrosoguanidine. The assumption that radical scavenging garlic constituents, i.e., molecules with sulfur moieties, might be responsible for the inhibitory effect of aqueous extract toward mutagenesis induced by radiation and radiomimetic compounds was confirmed by the results of subsequent experiments; 1) garlic extract attenuated the lethal effects of gamma-rays on repair-deficient E. coli strains; 2) the garlic constituent allicin (thio-2-propene-1-sulfinic acid S-allyl ester) is partly responsible for the reduced radiation-induced mutagenesis in Salmonella typhimurium TA 102. No such inhibitory effects were detected with alliin (S-allyl-L-cysteine sulfoxide) or cysteine; 3) aqueous garlic extract inhibited hydrogen-peroxide-induced lipid peroxidation. Results obtained in preliminary experiments with Chinese hamster ovary cells suggest that the *antimutagenic* properties of garlic extract are not restricted to procaryotic cells. Author-abstract.

TI Anticarcinogenic effect of betel leaf extract against tobacco carcinogens.

SO Cancer-Lett. 1989 Jun. 45(3). P 195-202.

JT CANCER LETTERS.

PT JOURNAL-ARTICLE (ART).

AB Epidemiological studies have implicated that betel quid offers some protection to tobacco induced carcinogenesis. Earlier studies in our laboratory have shown betel leaf extract (BLE) to be *antimutagenic* against standard mutagens and tobacco-specific N'-nitrosamines (TSNA), N'-nitrosonornicotine (NNN) and 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK). In the present study, we have tested the anticarcinogenic effect of BLE using Swiss male mice. Two protocols of study were used to test this effect. In the first protocol, the effect of BLE was tested against the standard carcinogen benzo(a)pyrene (BP) using Wattenberg's stomach tumor model, Cancer Res., 41 (1981) 2820-2823. In this protocol, BLE inhibited the tumorigenicity of BP to a significant extent. In the second protocol, the effect of BLE against the two tobacco-specific nitrosamines, NNN and NNK was studied using long-term studies on Swiss male mice. The nitrosamines were administered on the tongues of the mice, while the BLE was supplied in drinking water. Two doses of NNN (22 mg and 72 mg) and one dose of NNK (22 mg) were used. In this study, it was observed that the number of tumor bearing animals decreased, but the difference was significant only in the group treated with the low dose of NNN in combination with BLE. However, in all the BLE treated animals, irrespective of the dose of nitrosamine, the hepatic vitamin A and C levels were elevated significantly as compared to the corresponding nitrosamine-treated controls. These results indicate that BLE has a promising anticarcinogenic role to play in tobacco induced cancer.(ABSTRACT TRUNCATED AT 250 WORDS). Author-abstract.

TI Modification of the mutagenicity of aflatoxin B1 and N-methyl-N'-nitro-N-nitrosoguanidine by certain phenolic compounds.

SO Cancer-Lett. 1989 Jun. 45(3). P 177-82.

JT CANCER LETTERS.

PT JOURNAL-ARTICLE (ART).

AB Five natural and two synthetic phenolic compounds were tested for their ability to suppress mutagenicity of aflatoxin B1 (AFB1) and N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) in Salmonella typhimurium tester strain TA100. Caffeic acid and eugenol were observed to

inhibit mutagenicity of both the carcinogens, while chlorogenic acid was effective in the case of AFB1 alone and ellagic acid and butylated hydroxytoluene were found to be *antimutagenic* only for MNNG. These differential activities of the phenolic compounds appeared to be due to their different modes of action towards direct and indirect acting carcinogens. Author-abstract.

TI Presence of the dnaQ-rnh divergent transcriptional unit on a multicopy plasmid inhibits induced mutagenesis in Escherichia coli.

SO J-Bacteriol. 1989 Jun. 171(6). P 3144-51.

JT JOURNAL OF BACTERIOLOGY.

PT JOURNAL-ARTICLE (ART).

AB In Escherichia coli the dnaQ+ gene, which encodes epsilon, a fidelity subunit of DNA polymerase III, and the rnh+ gene, which encodes RNase H, share a promoter region but are transcribed in opposite directions. The presence of this divergent transcriptional unit on a multicopy plasmid inhibited by as much as 10-fold mutations induced by the SOS-dependent mutagens methyl methanesulfonate and UV light. Mutations in either gene eliminated the effect, suggesting that both genes contribute either directly or indirectly to the *antimutagenic* phenotype. Neither survival to mutagen exposure nor induction of the SOS response was comparably affected by the presence of the genes. Although the *antimutagenic* phenotype was partially suppressed by excess UmuDC proteins, which are required for SOS mutagenesis, the presence of the dnaQ+-rnh+ clone also reduced the induction of mutations by N-methyl-N'-nitro-N-nitrosoguanidine in cells deficient for SOS mutagenic processing. The results suggest that the presence of the dnaQ+-rnh+ divergent transcriptional unit interferes with an underlying mutagenic mechanism that is normally facilitated by the proteins induced as part of the SOS response. TI *Antimutagenic* specificity against spontaneous and nitrofurazone-induced mutations in Escherichia coli K12ND160.

SO Mutagenesis. 1989 Jan. 4(1). P 31-4.

JT MUTAGENESIS.

PT JOURNAL-ARTICLE (ART).

AB Escherichia coli K12ND-160 possesses characteristics which make it highly suitable for studies on *mutagenic/antimutagenic* specificity and has been used to investigate such effects for several agents. Nitrofurazone (NFZ) was used as a mutagen at non-lethal

concentrations; it causes mutation from fucose sensitivity to resistance (FucS----FucR) and from inability to utilize melibiose to melibiose utilization (Mel(-)----Mel+), but does not induce mutations from deoxygalactose sensitivity to resistance (DGAS----DGAR). Caffeine is mutagenic for reversions from lactose non-utilization to utilization (Lac(-)----Lac+) and mutations from FucS----FucR, but it is *antimutagenic* for mutations from 6-azauracil sensitivity to resistance (AzaUS----AzaUR) and Mel(-)----Mel+ reversions and produces no effect on spontaneous DGAS----DGAR mutations. Added guanosine and cytidine (G + C at 100 micrograms/ml each) exert *antimutagenic* activity against spontaneous Lac(-)----Lac+ reversion, but not against caffeine-induced Lac(-)----Lac+ reversions; a strong *antimutagenic* effect on spontaneous Mel(-)----Mel+ reversion is also observed. The addition of G + C does not result in either mutagenic or *antimutagenic* effects against spontaneous or NFZ-induced FucS----FucR or DGAS----DGAR mutations; it is, however, strongly mutagenic for AzaUS----AzaUR mutations. The 'natural *antimutagen',* chlorophyllin, is *antimutagenic* for DGAS----DGAR mutations, but fails to demonstrate such activity against spontaneous or caffeine-induced Lac(-)----Lac+ reversion, spontaneous or NFZ-induced Mel(-)----Mel+ reversion, or spontaneous or NFZ-induced FucS----FucR mutation.(ABSTRACT TRUNCATED AT 250 WORDS). TI Mutagenic and *antimutagenic* effects of 5-substituted 2'-deoxyuridines depending on the nature of the 5-substituent.

SO Arzneimittelforschung. 1988 Dec. 38(12). P 1820-4.

JT ARZNEIMITTEL-FORSCHUNG.

PT JOURNAL-ARTICLE (ART).

AB Various 5-substituted pyrimidine 2'-deoxyribosides with anti-herpes activity were investigated for their genotoxic activity. 5-Iodo-2'-deoxycytidine (IDC), 5-(2-chloroethyl)-2'-deoxycytidine (CEDC), 5-(3-chloropropyl)-2'-deoxyuridine (CPDU), (E)-5-(2-bromovinyl)-2'-deoxyuridine (BVDU), 5-ethyl-2'-deoxyuridine (EDU), 2'-deoxyuridine (DU) and 2'-deoxythymidine (DT) were non-mutagenic in Salmonella typh. as well as in V79 Chinese hamster cells, 5-Iodo-2'-deoxyuridine (IDU) was moderately mutagenic and 5-(2-chloroethyl)-2'-deoxyuridine (CEDU) was highly mutagenic in V79 cells; neither IDU nor CEDU were mutagenic in the bacterial assay. None of the compounds induced unscheduled DNA synthesis in primary rat hepatocytes. In addition, *antimutagenic* effects of 2'-deoxyuridines were discovered: in V79 cells, BVDU, EDU, DU and DT prevented the mutagenicity induced by CEDU; in these cells EDU also inhibited the mutagenicity induced by MNNG. In primary rat hepatocytes, IDU and EDU inhibited the induction of unscheduled DNA synthesis induced by MNNG, DMBA or UV-light. The compounds were

inactive at inducing differentiation in hematopoietic cells. The significance of these data, particularly with regard to the use of 5-substituted 2'-deoxyuridines in anti-herpes therapy, is discussed. Author-abstract.

SO J-Nat-Prod. 1988 Nov-Dec. 51(6). P 1226-31.

JT JOURNAL OF NATURAL PRODUCTS.

PT JOURNAL-ARTICLE (ART).

AB Maesol, a novel dimeric phenol, was isolated from seeds of *Maesa montana* and *Maesa indica*. Maesol was shown to have the formula C₂₈H₄₂O₄ with structure 1, a dimeric, symmetrical 1,12-bis(3,3'-dihydroxy-4,4'-dimethyl-5,5'-dimethoxyphenyl)dodecane. It is the first compound with such structure to be isolated from plant material. Structure elucidation was based largely on ¹H- and ¹³C-nmr techniques and comparison with a known synthetic isomeric dimer 3. Although crude extracts showed strong inhibition of 2-aminoanthracene activity against *Salmonella typhimurium* (T-98), the pure compound was inactive when tested for inhibition of the mutagenic activity of several mutagens. TI Protection against radiation-induced mutagenesis in V79 cells by 2-(aminopropyl)amino: ethanethiol under conditions of acute hypoxia.

SO Radiat-Res. 1989 Feb. 117(2). P 251-8.

JT RADIATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB The effects of the radioprotector 2-(aminopropyl)amino: ethanethiol (WR-1065) on radiation-induced cell killing and mutagenesis at the hypoxanthine-guanine phosphoribosyl transferase (HGPRT) locus in V79 Chinese hamster cells under hypoxic or aerobic conditions were examined. Conditions of acute hypoxia were attained by gassing 10(6) cells in 1-ml volumes in individual glass ampoules for 2 min with nitrogen. Ampoules were then sealed and incubated at 37 degrees C for 60 min. Following this treatment, cell survival after irradiation as expected was significantly enhanced. The effect of acute hypoxia on the formation of HGPRT mutants by irradiation was also investigated. Mutation frequencies were determined with a 6-day expression time and corrected for the number of spontaneous background mutants. Although mutation induction was approximately linear as a function of radiation dose under most conditions tested, it was significantly reduced in cell populations made acutely hypoxic prior to irradiation. Protection against mutation induction was apparent and similar when cells were irradiated in the presence of the radioprotector, regardless of whether they were also hypoxic or aerated. If cells were irradiated in air and then made hypoxic, no significant protection was still observed. These results suggest that the *antimutagenic* effect of WR-1065 is not due solely to its

ability to scavenge radiation-induced oxygen-free radicals, but rather that it may also modulate these effects through the scavenging of metabolically induced free radicals and/or the chemical repair of radiation-induced DNA lesions. Author-abstract.

TI Antimutagenicity of some citrus fruits in Salmonella typhimurium.

SO Mutat-Res. 1989 Mar. 222(3). P 141-8.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB The *antimutagenic* effect of 10 citrus fruit juices was observed against the mutagenicity of N-nitro-o-phenylenediamine (NPD) in TA97a and sodium azide in TA100 tester strains of Salmonella typhimurium using the Ames test. It was noticed that the juices of all these fruits reduced significantly the NPD and sodium azide induced revertant colonies. The inhibitory activity was enhanced if the mutagen and juice were co-incubated for about 30 min at 37 degrees C prior to performing the mutagenicity assay. Dilution with distilled water led to the reduction in the inhibitory activity. The *antimutagenic* activity of synthetic ascorbic acid or citric acid or combined ascorbic acid and citric acid was also seen. But the results with fruit juices tempted us to believe that in addition to ascorbic acid and citric acid, the presence of other factor(s) possessing *antimutagenic* properties cannot be ruled out. TI Sodium thiosulfate inhibits cisplatin-induced mutagenesis in somatic
tissue of Drosophila.

SO Environ-Mol-Mutagen. 1989. 13(2). P 97-9.

JT ENVIRONMENTAL AND MOLECULAR MUTAGENESIS.

PT JOURNAL-ARTICLE (ART).

AB The antitumor agent cisplatin was evaluated for genotoxicity in the
somatic tissue of Drosophila melanogaster in combination with the
nucleophilic compound sodium thiosulfate (STS). Third instar larvae
transheterozygous for mwh and flr3 were grown on media containing (1)
water, (2) 200 mM STS, (3) 0.05 mM cisplatin in 200 mM STS, or (4)
0.05 mM cisplatin. Wings of surviving adults were scored for the
presence of twin spots and both small and large single spots; 200 mM
STS was nongenotoxic in the assay. Whereas 0.05 mM cisplatin
significantly induced all three endpoints, 0.05 mM cisplatin in
combination with 200 mM STS was found to have no genotoxic activity.
Hence, STS possessed *antimutagenic* activity in the wing-spot assay
and completely inhibited cisplatin-induced mutagenesis and mitotic
recombination. Author-abstract.

strain TA98.

SO Teratogenesis-Carcinog-Mutagen. 1988. 8(4). P 215-24.

JT TERATOGENESIS, CARCINOGENESIS, AND MUTAGENESIS.

PT JOURNAL-ARTICLE (ART).

AB Chlorophyllin was studied for its *antimutagenic* activity against aflatoxin B1 in Salmonella typhimurium strain TA98 using the plate-incorporation test in the presence of S9 activation. Comparative antimutagenicity between chlorophyllin and certain commonly studied *antimutagens* (i.e., vitamins A, C, and E, retinoic acid, and beta-carotene) was also examined. A dose-related inhibition of aflatoxin B1 mutagenicity by chlorophyllin was observed, with the mutagenicity being abolished by 860 nmole chlorophyllin per plate. The inhibitory activity of chlorophyllin occurred only when cells were treated concurrently with chlorophyllin and aflatoxin B1. The *antimutagenic* potency of chlorophyllin was comparable to that of vitamin A and higher than that of retinoic acid and beta-carotene. Vitamins C and E had no effect on aflatoxin B1 mutagenicity under the conditions used. The results of toxicity tests and a reconstruction experiment showed that inhibition of the mutagenicity of aflatoxin B1 by chlorophyllin and the other active agents was due to antimutagenicity. TI Protection against polycyclic aromatic hydrocarbon-induced skin tumor initiation in mice by green tea polyphenols.

SO Carcinogenesis. 1989 Feb. 10(2). P 411-5.

JT CARCINOGENESIS.

PT JOURNAL-ARTICLE (ART).

AB Green tea is a popular beverage in China and Asia and has been shown to possess antipyretic, diuretic and several other pharmacological activities. The major constituents of green tea are polyphenols which have been found to possess antioxidant and *antimutagenic* properties. In this study green tea polyphenols (GTP) were evaluated as an anti-initiating agent against the skin tumorigenicity induced by polycyclic aromatic hydrocarbons (PAHs) in mice. In a complete skin tumorigenesis protocol using 3-methylcholanthrene the topical application of GTP to female BALB/c mice resulted in substantial protection against the onset and subsequent development of tumors. In the two-stage skin tumorigenesis protocol using 7,12-dimethylbenz`a:anthracene (DMBA) as the initiating agent followed by twice weekly applications of 12-O-tetradecanoylphorbol-13-acetate; (TPA) as tumor promoter, topical application of GTP to female SENCAR mice afforded significant protection against skin tumorigenicity. Oral feeding of GTP in drinking water to female SENCAR mice also protected against skin tumorigenesis in DMBA - TPA-treated animals. GTP when administered topically or orally significantly inhibited PAH - DNA adduct formation in epidermis after topical application of `3H:benzo`a:pyrene or `3H:DMBA. Our results suggest that GTP has substantial anti-skin-tumor-initiating activity against PAHs and could prove useful in protecting against some forms of human cancer.

SO Mutat-Res. 1989 Jan. 222(1). P 19-25.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Using the Ames Salmonella/microsome assay, we compared the *antimutagenic* activities of chlorophyllin, retinol, beta-carotene, vitamin C, and vitamin E against solvent extracts of coal dust, diesel emission particles, airborne particles, fried beef, and tobacco snuff. The results show that chlorophyllin inhibited 69% of the mutagenic activity of tobacco snuff and over 90% of that of the other 4 complex mixtures. Retinol inhibited 29-48% of the mutagenic activity of all 5 complex mixtures. beta-Carotene, vitamin C, and vitamin E inhibited, if any, less than 39% of the activity of the complex mixtures studied. Vitamin C enhanced the mutagenicity of airborne particles. These results indicate that for these dietary and environmental complex mixtures chlorophyllin is a more effective *antimutagen* than retinol, beta-carotene, vitamin C, and vitamin E.

antimutagen anthraflavic acid.

SO Food-Chem-Toxicol. 1988 Nov-Dec. 26(11-12). P 909-15.

JT FOOD AND CHEMICAL TOXICOLOGY.

PT JOURNAL-ARTICLE (ART).

AB Administration of the *antimutagen* anthraflavic acid to rats gave rise to significant increases in the hepatic microsomal O-deethylations of ethoxyresorufin and ethoxycoumarin, but not in the O-dealkylation of pentoxyresorufin nor in cytosolic glutathione S-transferase activity. Immunoblot studies of solubilized microsomes from anthraflavic acid-treated rats revealed that anthraflavic acid induced the apoproteins P-450 I A1 and A2 but not P-450 B1 and B2. Pretreatment with anthraflavic acid resulted in a marked increase in the in vitro bioactivation of 2-amino-6-methyldipyrido`1,2-a:3',2'-d:imidazole and 2-amino-3,2-amino-3-methylimidazomethylimidazo`4,5-f:-quinoline (IQ) to mutagenic intermediate(s); IQ is a carcinogen against which anthraflavic acid has displayed strong *antimutagenic* effect in the Ames test when incorporated into the metabolic activation system. The increase in mutagenicity of IQ was the result of enhancement of both the microsomal and cytosolic activation steps. It is concluded that anthraflavic acid is a specific inducer of P-450 I proteins in the rat and this compound is not only unlikely to exhibit any anticarcinogenic effect in vivo but may act as a co-carcinogen. SO Mutat-Res. 1988 Dec. 202(2). P 387-91.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).

AB The term *'antimutagen'* was originally used to describe an agent that reduces the apparent yield of spontaneous and/or induced mutations, regardless of the mechanisms involved. The *'antimutagens'* include 'desmutagens' and *'bio-antimutagens'*. In this article, our attention was focused on the *bio-antimutagens* affecting DNA repair in bacteria. Cobaltous chloride reduced the frequency of mutations in *Escherichia coli* induced by MNNG. The possibility that metal compound inhibits the growth of mutagen-treated cells was examined. The results clearly showed that the *antimutagen* surely reduces the mutation rate. The target of cobaltous chloride was found to be cellular factors including Rec A. Vanillin and cinnamaldehyde had strong *antimutagenic* activities against UV, 4NQO and AF-2. They stimulated Rec A-dependent recombination repair functions in the mutagen-treated cells. Among plant materials, tannins possess *antimutagenic* activity against UV-induced mutations in *E. coli*. It has been found that tannic acid stimulates the excision repair encoded by the *uvrA* gene thereby reducing the yield of mutants. Substances which are *antimutagenic* in bacterial systems also had *antimutagenic* activity in cultured mammalian cell systems. Vanillin reduced the frequency of

mutagen-induced chromosomal aberrations. Author-abstract. 16 Refs.

TI Antimutagenesis by shift in monooxygenase isoenzymes and induction of epoxide hydrolase.

SO Mutat-Res. 1988 Dec. 202(2). P 335-42.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).

AB The widely occurring aromatic and olefinic structural elements can be transformed into epoxides by microsomal monooxygenases. These epoxides may react with nucleophilic centers in the cell and thereby covalently bind to DNA, RNA and protein. Such a reaction may lead to cytotoxicity, allergy, mutagenicity and/or carcinogenicity, depending on the properties of the epoxide in question. An important contributing factor is the presence and relative activity of enzymes controlling the concentration of such epoxides. There are several microsomal monooxygenases which differ in activity and substrate specificity. On individual substrates individual cytochromes P-450 often preferentially attack at one specific site different from that attacked by others. Some of these pathways lead to reactive products, others are detoxification pathways. Also important are the enzymes which metabolize epoxides, such as epoxide hydrolases and glutathione transferases. Such enzymes can act as inactivating and in some specific cases also as co-activating enzymes. Moreover, precursor-sequestering enzymes such as dihydrodiol dehydrogenase, glucuronosyl transferases and sulfotransferases are important for the control of reactive epoxides. These enzymes themselves are subject to control by many endogenous and exogenous factors. By virtue of their contribution to the control of mutagenic metabolites such modulators can exert *antimutagenic* activity. An especially interesting *antimutagen,* whose mechanism of *antimutagenic* action is modulation of mutagen-metabolizing enzymes, is trans-stilbene oxide. This agent selectively induces the synthesis of some specific cytochrome P-450 isoenzymes at the expense of others, so that the metabolism of benzo`a:pyrene is shifted from the route leading to the highly mutagenic 7,8-dihydrodiol 9,10-epoxides to the route leading to the much less mutagenic 4,5-epoxide. Moreover, the same agent potently induces microsomal epoxide hydrolase which inactivates the latter epoxide. The combined effects lead to a drastic *antimutagenic* effect, the molecular mechanism of which is given by these changes in mutagen-metabolizing enzymes. Author-abstract. 39 Refs.

TI *Antimutagens* against spontaneous and induced reversion of a lacZ frameshift mutation in E. coli K-12 strain ND-160.
 SO Mutat-Res. 1988 Nov. 202(1). P 19-23.
 JT MUTATION RESEARCH.
 PT JOURNAL-ARTICLE (ART).
 AB Isopropyl-beta-D-thiogalactoside (IPTG), at 0.5 or 1.0 mM, is shown to reduce spontaneous, and to virtually abolish caffeine- or quinacrine-induced reversions of the lacZ frameshift mutation in E. coli ND160. Guanosine at 200 micrograms/ml and Co2+ at 15 micrograms/ml had an erratic partial *antimutagenic* effect on spontaneous lac+ reversions. All 3 agents reduce caffeine-induced (500 micrograms/ml) mutagenesis. Spermine (250 micrograms/ml) also reduces quinacrine-induced Lac+ reversion frequencies in this system. Author-abstract.

 TI *Antimutagenic* action of methionine in Chinese hamster fibroblasts: an opposite of methionine mutagenicity.
 SO Anticancer-Res. 1988 Jul-Aug. 8(4). P 701-5.
 JT ANTICANCER RESEARCH.
 PT JOURNAL-ARTICLE (ART).
 AB Serially propagated fibroblast clones were treated with 25-mM methionine and a thioguanine resistance assay was performed at each passage to measure mutagenesis at the HGPRT locus. The spontaneous frequency of thioguanine resistant mutants before treatment was less than 5×10^{-6} in four clones and 22×10^{-6} in one clone. These values dropped 10- to 100-fold and remained so until the methionine was withdrawn, then returned to, or overshoot, the initial values. It is proposed that these fibroblasts, unlike their previously described RSV-transformed counterparts, possess a repair enzyme capable of an adaptive response to S-adenosylmethionine, the metabolite thought to be responsible for methionine mutagenicity in vivo.  TI *Antimutagenic* effects of several subfractions of extract from wheat sprout toward benzo(a)pyrene-induced mutagenicity in strain TA98 of Salmonella typhimurium.
 SO Mutat-Res. 1988 Oct. 206(2). P 221-5.
 JT MUTATION RESEARCH.
 PT JOURNAL-ARTICLE (ART).
 AB The aqueous extract from wheat sprouts contains some *antimutagenic* factor(s). The factor(s) abolish(es) the activity of aryl

hydrocarbon (benzo`a:pyrene) hydroxylase (AHH) in the S9 fraction from Aroclor-treated rat livers and also inhibit(s) the mutagenic activity of benzo`a:pyrene (B(a)P) in the Ames test. The extract (fraction S30) was subjected to initial fractionation by thermal treatment, 3 24-h cycles of dialysis and ultrafiltration. The antigenotoxic activity of fraction S30 amounted to 98% and was unchanged by thermal treatment (100 degrees C, 10 min). Both the dialysate and the dialysis fluid inhibited the mutagenic effect of B(a)P by 48.4 and 48% respectively. The microsomal subfraction inhibited the mutagenicity only in 10%, and the postmicrosomal subfraction in 68%. It is concluded that the extract from wheat sprouts contains at least 2 heat-resistant compounds (or groups of compounds) located within the cell cytosol and showing *antimutagenic* activity: one group is of low molecular weight and another of high MW. Alternatively, low-molecular compounds could either be free or bound to high-molecular compound(s). Author-abstract.

TI The mutagenic potencies of plant extracts containing quercetin in Salmonella typhimurium TA98 and TA100.

SO Mutat-Res. 1988 Oct. 206(2). P 201-8.

JT MUTATION RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB Four commercial ethanolic plant extracts, Tinctura Alchemillae, Extractum Crataegi, Extractum Myrtilli and Tinctura Hyperici, were tested for their mutagenicity in Salmonella typhimurium TA98 and TA100 with and without S9 mix obtained from rats pretreated with phenobarbital. The extracts studied differed greatly in their mutagenic potencies but exhibited a very similar mutation pattern in which the strongest effect was always seen in tester strain TA98 with S9 mix. Simultaneously we investigated the extracts for the presence of quercetin and kaempferol. Only quercetin was detected in small amounts by thin-layer chromatography (TLC). The fractions containing quercetin were separated and collected using a Sephadex LH-20 column. Two different methods were employed to estimate the amount of quercetin in the extracts: a colorimetric assay developed by Christ and Muller, and a complexometric method by Belikov. The quercetin concentrations ranged between 2 mg (Tinctura Alchemilla) and 89 mg (Tinctura Hyperici) per 100 g of extract. We suggest that the mutagenicity of the 4 plant extracts is mainly due to the presence of quercetin for the following reasons: (1) all the plant extracts exhibit a mutation pattern which is very similar to that of quercetin, (2) the mutagenic potential of the extracts correlates well with their quercetin content, considering the fact that plant extracts are very complex mixtures often containing toxic or *antimutagenic* compounds. SO Gematol-Transfuziol. 1992 Jul-Aug. 37(7-8). P 31-3.

JT GEMATOLOGIIA I TRANSFUZIOLOGIIA.

PT JOURNAL-ARTICLE (ART).

AB A total of 878 children from the regions with unfavourable radiation situation were investigated in varying periods after the catastrophe. The data obtained were compared with the results of the study of 317 children from "pure" regions. Morphological, metabolic and ultrastructural changes were detected in blood cells of the children from radioactively contaminated regions after the *Chernobyl* catastrophe. A tendency to normalization of these parameters was noted in the time course of the post-catastrophe period. No clear relationship was established between the dose and effect. However, significant correlations between the severity of disorders in blood cells and the intensity of free-radical processes in the body were recorded. Author-abstract.

TI Estimation of absorbed dose to evacuees at pripyat-city using ESR measurements of sugar and exposure rate calculations.

SO Appl-Radiat-Isot. 1994 Jan. 45(1). P 113-20.

JT APPLIED RADIATION AND ISOTOPES.

PT JOURNAL-ARTICLE (ART).

AB The external absorbed doses in Pripyat-city resulting from the *Chernobyl* nuclear power plant accident have been evaluated from eight ordinary granulated sugar samples using the electron spin resonance method. The indoor and outdoor external doses to the people evacuated from Pripyat-city at about 36 h after the *Chernobyl* accident have been estimated using both data from the eight household sugar samples present in Pripyat-city prior to and during the accident and information on the type of buildings and survey-meter measurements of the exposure rates there. The absorbed dose to the evacuated people, as estimated from the exposure rates calculated in combination with the sugar dosimetry data, agree approximately with the reported average effective dose equivalent to such people, which was derived from both calculations and exposure-rate surveys. If each person in Pripyat-city could remember exactly the proportion of time spent indoors before being evacuated after the accident, the absorbed dose could roughly be estimated from the relationship between the documented external dose outdoors during the period between the accident and evacuation and the length of the period spent indoors by each individual prior to evacuation. It is suggested that as little as 1 g of sugar would be one of the most useful emergency dosimeters for people inside their dwellings, at least for absorbed doses greater than about 0.02 Gy.

TI Thyroid doses resulting from the Ukraine *Chernobyl* accident--Part I: Dose estimates for the population of Kiev.

SO Health-Phys. 1994 Feb. 66(2). P 137-46.

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB In the context of the radiation exposure of the Ukrainian population resulting from the *Chernobyl* accident, the quantification of the thyroid doses due to iodine incorporation is of special interest. This first part of a series of planned publications deals with the dose and risk estimation for Kiev citizens. Although these doses are expected to be considerably lower than those for some other regions of Ukraine, the investigations started with this population because the quantification of the thyroid doses due to iodine incorporation is of special interest. This first part of a series of planned publications deals with the dose and risk estimation for Kiev citizens. Although these doses are expected to be considerably lower

than those for some other regions of Ukraine, the investigations started with this population because of the availability of rather reliable measurements and because of the size of this population. The methods developed allowed the estimation of individual thyroid doses. The average values of individual thyroid doses for five age groups (birth years 1983-1986, 1979-1982, 1975-1978, 1971-1974, and < 1971) are 104, 62, 19, 18, and 41 mGy, respectively. The collective thyroid doses were estimated as 83×10^3 person-Gy for those born before 1971 and as 38×10^3 person-Gy for younger inhabitants. The numbers of expected thyroid cancers in the whole Kiev population are 66 and 130, respectively. Author-abstract.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).

AB The topic "Thyroid and Radiation" is both an old and a new area to be solved by human beings. The thyroid is an organ that is usually susceptible to exposure to ionizing radiation, both by virtue of its ability to concentrate radioiodine (internal radiation) and by routine medical examination: Chest X-ray, Dental X-ray, X-irradiation of cervical lymphnodes etc. (external radiation). Iodine-131 is widely used for the therapy of Graves' disease and thyroid cancers, of which the disadvantage is radiation-induced hypothyroidism but not complications of thyroid tumor. The thyroid gland is comparatively radioresistant, however, the data obtained from Hiroshima, Nagasaki and Marshall islands indicates a high incidence of external radiation-induced thyroid tumors as well as hypothyroidism. The different biological effects of internal and external radiation remains to be further clarified. Interestingly, recent reports demonstrate the increased number of thyroid cancer in children around *Chernobyl* in Belarus. In this review, we would like to introduce the effect of radiation on the thyroid gland at the molecular, cellular and tissue levels. Furthermore the clinical usefulness of iodine-131, including the safety-control for radiation exposure will be discussed. Author-abstract. 50 Refs.

JT SCIENCE OF THE TOTAL ENVIRONMENT.
PT JOURNAL-ARTICLE (ART).
AB From the analysis of experimental data on radioactive contamination of various fish, it is suggested that predatory fish specimens can be used as bioindicators of radionuclide accumulation in reservoir food chains of the *Chernobyl* emergency area. The increased content of cesium radionuclides were detected in the muscle tissue of predatory fish collected in various regions of the *Chernobyl* emergency area. In most of the water bodies studied, maximum contamination levels of predatory fish by radionuclides of cesium occurred in 1987-1988, whereas in 'nonpredatory' fish the concentration of cesium was maximum, as a rule, in the first year following the accident. The exposure doses of fish of various ecological groups and ages are estimated. The exposure doses of various population groups, using fish from contaminated water bodies, are also estimated. When forming the environmental data bank for the *Chernobyl* accident zone it is suggested that perch, pike-perch and pike be used as bioindicators of radioactive contamination of food chains.

JT RISK ANALYSIS.
PT JOURNAL-ARTICLE (ART).
AB An assessment of the radiological consequences that would result for the population of Greece from postulated major nuclear accidents in the Kozloduy nuclear power station in Bulgaria is performed. Kozloduy lies at a distance of 225 km from the northern borders of Greece and contains six reactors, all of the Russian WWER type. The postulated accidents that are classified as level 7 accidents on the International Nuclear Event Scale, involve significant releases of radioactive materials into the environment, and widespread health and environmental effects. The analysis is performed by the MACCS code. The estimated consequences are compared to the corresponding actual impact of the *Chernobyl* accident in Greece. The results of the analysis indicate that, under the conservative assumptions adopted, the radiological consequences of the most severe accidents considered would be about 1.5 orders of magnitude larger than the actual radiological consequences of the *Chernobyl* accident. SO Sci-Total-Environ. 1993 Sep 24. 137. P 289-305.

JT SCIENCE OF THE TOTAL ENVIRONMENT.

PT JOURNAL-ARTICLE (ART).

AB A large proportion of the area contaminated by the *Chernobyl* accident in the former USSR is forested and has presented unique problems when considering appropriate post-contamination management and clean-up techniques. These problems are related to the forest's role as both a source and sink for radioactive contamination. Although it has been suggested that resuspension from forested areas may provide a secondary source of contamination to adjacent land, data collected after the Kyshtym and *Chernobyl* accidents suggest that forest ecosystems may also be effective in limiting the further spread of contamination away from the point of initial deposition and that this effect will increase over time. Such evidence serves to highlight the importance of these ecosystems in influencing the behaviour of radionuclides immediately after their release to the environment. Management practices for forested areas adopted since 1986 are described and a critical appraisal is presented of engineering-based countermeasures implemented over the initial post-accident period. These were intended to remove large quantities of contaminated materials from the forest environment. However, it is suggested that the natural processes of self-decontamination of trees and forest floor litter layers are sufficiently rapid and efficient to

necessitate radical alterations to the technology based approaches adopted in the first 2 years after the *Chernobyl* accident.

TI Management methods of reducing radionuclide contamination of animal
food products in semi-natural ecosystems.

SO Sci-Total-Environ. 1993 Sep 24. 137. P 249-60.

JT SCIENCE OF THE TOTAL ENVIRONMENT.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).

AB Countermeasures involving changes in management practices which are
suitable for use in semi-natural ecosystems are described. Most of
the relevant information relates to radio-caesium, but the
applicability for some other radionuclides has also been evaluated.
Improved live-monitoring techniques for radiocaesium, developed since
the *Chernobyl* accident, allow the identification of animals whose
contamination levels exceed the intervention limits, so that
countermeasures can be effectively chosen and targeted. Generally
the most effective approach for domesticated and semi-domesticated
animals is either to remove contaminated animals from the affected
area or to provide uncontaminated feed. Uncontaminated feed is given
continuously for dairy animals or in the final fattening stages for
meat-producing animals. The introduction of other effective changes
in management practices, such as changing hunting seasons for game,
or slaughtering at a time of year when the animals have been grazing
on less contaminated herbage, depends on a good understanding of the
behaviour of radionuclides in these ecosystems. In practice, the
most effective countermeasures which can be used to reduce radionuclide
contamination of animals in semi-natural ecosystems will be obtained
by a combination of both management changes and the use of chemical
binders to prevent gut absorption. Author-abstract. 31 Refs.

PT JOURNAL-ARTICLE (ART).

AB The same chemicals can be used for reduction of radionuclide transfer
to animals whether kept on farms or grazing in semi-natural and
natural habitats. However, different techniques are required for
administration of the active compounds. Dairy ruminants may be
treated effectively by inclusion of chemicals in supplemental

concentrates. Practical experience gained after the *Chernobyl* accident has shown that both clay minerals and hexacyanoferrates are effective in preventing high radiocaesium levels in animal products. Chemicals such as bentonite clays and CaCO_3 , used for reduction of ^{137}Cs and ^{90}Sr transfer respectively, must be fed in hectogram quantities and are only practical for dairy animals in semi-natural ecosystems. Salt licks and sustained release boli with hexacyanoferrates as caesium binders have been developed and used successfully after the *Chernobyl* accident for meat producing cattle, sheep and reindeer which graze freely for extended periods. Daily doses of 25-300 mg in sheep and 250-2000 mg in cows reduces ^{137}Cs accumulation 2-10-fold. Binders for ^{90}Sr have not been tested in grazing animals. Stable iodine could be provided in salt licks and indwelling rumen boli at rates required to block radioiodine uptake by the thyroid gland. Boli and salt licks are highly cost effective in reducing doses to man when compared to interdiction of food from farm animals. Author-abstract.

AB Countermeasures taken in Belarus to reduce transfer of radiocaesium from feeds to animals have combined live monitoring and monitoring of radiocaesium (^{137}Cs and ^{134}Cs) in bulk milk on dairy farms with the setting of upper limits for radionuclide contents for animal feeds. Only uncontaminated feeds have been used in the final fattening of animals before slaughter. Combined with widespread soil management programmes these measures have allowed the continued use of the majority of contaminated agricultural lands without substantial changes in farming practices. PT JOURNAL-ARTICLE (ART).
AB In order to detect characteristic regional differences or temporal changes of ^{129}I concentrations in the biosphere, thyroids from humans, grazing livestock, and herbivorous wildlife species (reindeer

and roedeer) were collected in various areas of the world which are not affected by reprocessing plants. For reasons of comparison, all samples were analyzed for their $^{129}\text{I}:\text{}^{127}\text{I}$ atom ratios. Human and bovine thyroids taken from the 10th region in Southern Chile (39 degrees-41 degrees South) indicated values of the $^{129}\text{I}:\text{}^{127}\text{I}$ atom ratio between 1.1×10^{-9} and 2.0×10^{-9} and between 1.2×10^{-10} and 9×10^{-9} , respectively. They showed no significant increase in the concentration of biospheric ^{129}I in comparison with that established in the pre-nuclear age. Atom ratios found in human thyroids collected in Lower Saxony (Federal Republic of Germany), which is a region not directly affected by reprocessing plants, exhibited $^{129}\text{I}:\text{}^{127}\text{I}$ values between 8×10^{-9} and 6×10^{-8} from February 1988 to September 1990. Thyroid glands of reindeer and roedeer as well as heather, moss, and lichen were taken from the Vilhelmina, Heby, and Gavle communes in Sweden and analyzed for ^{129}I and ^{127}I . All three communes were found to be seriously contaminated by fallout from the *Chernobyl* accident. Highest $^{129}\text{I}:\text{}^{127}\text{I}$ atom ratios between 3.5×10^{-7} and 1×10^{-6} were found in the Gavle commune (approximately 150 km northwest of Stockholm) where the highest ^{137}Cs ground deposition ($70\text{--}80 \text{ kBq m}^{-2}$) was measured. Two soil samples taken from Krasnaya Gora and Mirny locations in Russia (approximately 200 km northeast of *Chernobyl*) exhibited ratios of about 1×10^{-6} . These locations showed a ^{137}Cs ground deposition of 370 and 1,300 kBq m^{-2} , respectively. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB The quantitative composition of the peripheral blood, enzymatic activity of neutrophils and hypoxic ventilatory drive were determined in people working at the *Chernobyl* NPP during sojourn for 28 days in the Caucasus mountains at 220 m altitude with a periodical climbing up to 4200 m. At the initial state we found neutropenia, lymphocytosis, an increase in the number of prolymphocytes and big hairy lymphocytes, a decrease in the number of small lymphocytes, fall in activity of enzymes responsible for oxygen-dependent and oxygen-independent mechanisms of bactericidity. The indices of sensitivity to the hypoxic respiration stimulus did not essentially differ from the norm. Staying at altitude promoted normalization of the number of segmento-nuclear neutrophils, lymphocytes (their small population, in particular), an increase in the number of eosinophiles of the peripheral blood. Changes in the activity of myeloperoxidase, NADP-oxidase and cationic proteins in the neutrophils were observed.

A considerable increase of the ventilatory drive to the hypoxic respiration stimulus was determined. Accentuation of fermentative transformations proved to be closely related to the ventilatory response to hypoxia: weak activation of NADP-oxidase and a decrease of myeloperoxidase activity were observed in people with initially low respiration reactivity, while a considerable increase in activity of these enzymes and in content of cationic proteins was observed in people with high respiration reactivity. Individual peculiarities of the reaction to staying at altitude should be taken into account when developing particular methods of immune correction.

AB External irradiation to the thyroid, even at low doses, induces subsequent development of thyroid nodules and carcinomas, with an estimated incidence of five per one million people per year if they have been exposed to 1 rad. Larger doses are associated with hypothyroidism. External irradiation also induces thyroid hyperplasia and is associated with an increased incidence of thyroid autoimmunity and the development of thyroiditis and Graves' disease. ¹³¹I, used in the treatment of Graves' disease and thyroid cancer for nearly 50 years, has not been associated with an increased incidence of thyroid cancer. Nevertheless, caution is advisable in use of radioiodide therapy in adolescents. Low levels of fallout from nuclear explosions probably have minimal, if any, effect on the thyroid; but recent high-level exposure in individuals near *Chernobyl* is reported to be associated with the development of thyroid malignancies in children. AB A disaster has been defined as a disruption of human ecology that exceeds the capacity of the community to function normally. Little is known about the adverse effects of natural disasters on reproductive outcomes. Important lessons can be derived from several

disasters caused by human factors, such as the Minamata Bay disaster. Adverse reproductive outcomes include infertility, early pregnancy loss, stillbirths, congenital malformations, and serious developmental disabilities such as cerebral palsy and mental retardation. Recent disasters like the *Chernobyl* and Bhopal explosions have provided important lessons on the need for accurate and sound information about the risk of prenatal exposures for adverse reproductive outcomes. To study questions of adverse reproductive outcomes and disasters requires a well-planned approach. It should include early development of surveillance for adverse reproductive outcomes, analytic studies on the risk of disasters from direct and indirect effects, sensitive methods to measure early pregnancy loss, and long-term follow-up programs to assess outcomes such as developmental disabilities. PT JOURNAL-ARTICLE (ART).

AB This paper reports the results of a comprehensive survey of the effects of the accidental release of radiation caused by the accident at the *Chernobyl* nuclear power station in April 1986. The accident and the resulting release of radiation and radioactive products into the atmosphere produced the most serious environmental contamination so far recorded. We have concentrated on evaluating the outcomes and health risks to women, their reproductive situation, and consequences for their progeny. We have concentrated on two well-defined areas: the Chechersky district of the Gomel region in Belorussia and the Polesky district of the Kiev region in the Ukraine. A number of investigations were carried out on 688 pregnant women and their babies, and data were obtained from 7000 labor histories of the development of newborns for a period of 8 years (3 years before the accident and 5 years after it). Parameters examined included birth rate, thyroid pathology, extragenital pathology such as anemias, renal disorders, hypertension, and abnormalities in the metabolism of fats, complications of gestation, spontaneous abortions, premature deliveries, perinatal morbidity and mortality, stillbirths and early neonatal mortality, infections and inflammatory diseases, neurological symptoms and hemic disturbances in both mothers and infants, trophic anomalies, and biochemical and structural changes in the placenta. Several exogenous, complicating influences were also considered such as psycho-emotional factors, stress, lifestyle

changes, and others caused directly by the hazardous situation and by its consequences such as treatment, removal from affected areas, etc.(ABSTRACT TRUNCATED AT 250 WORDS). Author-abstract.

AB Several radioecological experiences with isotopes of ruthenium, iodine, caesium and barium, obtained after the reactor accident of *Chernobyl,* are reported. It was found that for a wet deposition barium was the element with the highest retention on grass. The retention of caesium was lower by a factor of 1.6, retention of iodine by a factor of 2.4 and retention of ruthenium by a factor of 3.5. Former data on the caesium transport in cereals from leaves to grain were confirmed. Depending on the conditions the iodine transfer factor for milk varied between 0.002 and 0.007 d.kg-1. The caesium transfer factor for milk was (0.003 +/- 0.0006) d.kg-1 and was found to be relatively constant in the years 1986-1988. In 1991, the values were higher by a factor of 2-5. Radioecological model results of whole-body burdens in Southern Bavaria showed a reduction of the caesium ingestion doses due to countermeasures and spontaneous changes of consumption habits in the first 2 months by a factor of 5 and till the end of 1987 by a factor of 1.5. The model results agree well with the range of measured whole-body burdens. One month after

the deposition, the external exposures in urban environments due to ruthenium, caesium and barium isotopes were found to be reduced by a factor of 2, compared with open lawns, in the case of iodine the reduction was even a factor of 2.5. External exposures of a population group from the Munich area were determined by thermoluminescence dosimetry. The results are in accordance with the spectral measurements of external dose rates in urban environments. Author-abstract.

JT ONTOGENEZ.
PT JOURNAL-ARTICLE (ART).
AB Genotoxic effects during microsporogenesis and gametogenesis were studied in barley of the waxy strain grown on 3 experimental plots situated in the region of the *Chernobyl* disaster (plot 1 in the town of *Chernobyl,* plots 2 and 3 in the town of Yanov, 3 km away from the damaged power plant). It was determined that an increased level of radionuclide pollution and chronic irradiation during ontogenesis results in higher incidence of meiotic disturbances and abnormalities during formation of the male gametophyte. Incidence of waxy reversions in pollen grains depends on the activity of radionuclide pollutants as well. We suggest that selection affecting both diplont and haplont forms will provide for the absence of significant aberrations in subsequent plant generations. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB One specific area in the Federal Republic of Germany experienced a particularly high contamination by fallout from the *Chernobyl* reactor accident in 1986. The individuals living there received an additional radiation exposure from the fallout of about 0.8 mSv in 1986, which had decreased to about 0.2 mSv in 1989. Blood samples for chromosome analyses were collected from 29 different individuals during the period 1987-1991. About 44,000 cells were scored. The individuals were subdivided according to sampling time. In 1987/88, the mean frequency of dicentrics and centric rings (dic + Rc) was 2.45 ± 0.42 per 1000 cells and that for excess acentrics (ace) was 8.20 ± 0.90 per 1000 cells. In the following 2 years the mean yields per 1000 cells for dic + Rc were 1.60 ± 0.40 and 1.79 ± 0.42 , respectively, and that for ace 8.18 ± 0.90 and 6.92 ± 0.83 , respectively. The mean yields for chromatid breaks (cbr) per 1000 cells in the same periods were 4.96 ± 0.60 , 6.79 ± 0.82 , and 5.14 ± 0.71 , respectively. In addition, individuals were investigated as controls in two different areas where the exposure doses from the *Chernobyl* fallout were lower by one order of magnitude. In one control area, the mean frequency of structural chromosome aberrations was found to be 2.58 ± 0.36 dic + Rc, 9.62 ± 0.69 ace, and 6.54 ± 0.57 cbr per 1000 cells (20 individuals, approximately 20,000 cells). In the other control area, the mean yields were 1.91 ± 0.42 , 8.63 ± 0.89 , and 5.90 ± 0.73 , respectively, per 1000 cells (11 individuals, approximately 11,000 cells). These yields show no significant trend, either with sampling time or with contamination level for any of the three aberration types. Five individuals from the highly contaminated area who were investigated in 1987, were reinvestigated in 1991. On the basis of about 10,000 cells, the mean yield of dic + Rc per 1000 cells decreased significantly from 2.69 ± 0.52 to 1.40 ± 0.37 ($p < 0.05$). In nine individuals from the contaminated area, the content of cesium nuclides was measured using a whole body counter. No relation between the physically calculated radiation doses to blood and the frequency of dicentrics determined in 1987/88 was found ($r = 0.41$). Author-abstract.

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB The content of $^{239,240}\text{Pu}$ was determined in the daily diet collected in northeastern Poland (Bialystok) from March 1987 to May 1992. The estimated annual intake of plutonium decreased from 774 mBq y⁻¹ in the first year after the *Chernobyl* accident down to approximately 90 mBq y⁻¹ in the sixth year. Large fluctuations of daily intake in the first 2 y suggested that a large fraction of plutonium in the daily diet originated from the external contamination. Assuming the fractional absorption factor of 10⁽⁻⁵⁾ for externally contaminated foodstuffs and 10⁽⁻³⁾ for root uptake, the assimilated $^{239,240}\text{Pu}$ would be in the range from approximately 0.02 mBq up to approximately 2 mBq for the period studied. AB The paper deals with mycobiota of radionuclide-polluted soils of seven stationary posts in the 30-kilometer zone of the *Chernobyl* NPP and one in the vicinities of Kiev (Feofaniia). The lengths of light-and dark-coloured fungal mycelium were determined in the soil under study by the method of membrane filters for 1987-1989. Data obtained have been analyzed with the account of the radioactivity level of the soil samples, season and depth of the sampling horizon. The dynamics of mycelium content in soils has been traced which evidences for its seasonal changes and prevalence of dark-pigmented mycelium at the beginning which then was changed by predominance of light-coloured mycelium. It is supposed that radioactive contamination of soil is one of considerable components of the whole complex of ecological factors which determine the dynamics of fungal mycelium content in soil. TI Radiocaesium transfer to sheep's milk as a result of soil ingestion.

SO Sci-Total-Environ. 1993 Aug 15. 136(1-2). P 13-24.

JT SCIENCE OF THE TOTAL ENVIRONMENT.

PT JOURNAL-ARTICLE (ART).

AB Soil ingestion as a source of radiocaesium contamination to ruminants was studied by measuring the transfer coefficient to sheep milk. Eight lactating ewes, housed in individual metabolism cages, were used. Fifty grams per day of heavily contaminated sandy topsoil, collected in 1990 from the *Chernobyl* area, were administered orally to the animals for a period of 1 week. The daily dose intake in ^{137}Cs was 1835 Bq day^{-1} . During this contamination period, daily milk production and excreta output were measured. The ewes were monitored for an additional 7 day decontamination period, while they fed on uncontaminated feed. Transfer coefficients were obtained through a best fit (minimum χ^2) of the data to predictions of a linear compartment model. The values obtained were $f_m = (2.6 \pm 0.7) \times 10^{-2}$ and $f_{mu} = (5 \pm 2) \times 10^{-2} \text{ days kg}^{-1}$ for radiocaesium transport to milk and urine, respectively. These results suggest that soil ingestion can be a major source of radiocontamination for sheep and other free-grazing ruminants.

Comparison of our results with soil-to-milk transfer coefficient values derived in two recent independent experiments suggests that there might be a strong dependence of radiocaesium availability on soil composition. Author-abstract.

SO Sci-Total-Environ. 1993 Aug 15. 136(1-2). P 1-11.

JT SCIENCE OF THE TOTAL ENVIRONMENT.

PT JOURNAL-ARTICLE (ART).

AB Transfer coefficients for radiocaesium transport from a sheep's diet to blood, muscle, lung, liver, kidney, spleen heart, brain, rumen, intestines and fat were measured in a controlled experiment involving 50 adult ewes. The animals were fed dry grass and wheat, both contaminated with *Chernobyl* fallout debris, for a period of 60 days. During this period half of the animals were killed at regular intervals and samples of their blood and tissues were measured for radiocaesium concentration. The rest of the animals were returned to uncontaminated food and were monitored for radiocaesium concentration through periodic slaughtering for an additional 60 days. Transfer coefficients were extracted from the plateau reached at the end of the contamination phase. The data were also analyzed by means of a recently proposed linear multiple compartment model and transport rate parameters for each compartment were extracted. Transfer coefficients computed through the model's transport rate parameters show remarkable agreement with the experimentally obtained values. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB The effect of chronic low-level radiation exposure on radiosensitivity to posterior acute irradiation at high doses has been studied. Cells and mice were exposed within the ten-kilometer zone of *Chernobyl* disaster during various spaces of time (1-12 days), then over one or more days were additionally irradiated by doses of 1-4 Gy. It was shown that no adaptive response was developed under chronic exposure of cells and mice within the zone of disaster. On the contrary increased sensitivity to posterior irradiation was revealed. The number of cytogenetic damages of cultured tissue cells and marrow cells (chromosome aberrations and micronuclei) increases, the spectrum of aberrations being shifted to chromosome type, cells with multiaberration appearing. The decay of chromatine increases indicating an interphase death; the number of leucocytes in peripheral blood decreases. Author-abstract.

AB The nature of the radionuclide contamination resulting from *Chernobyl* disaster is in its spatial and aggregate heterogeneity determined by the interaction of systematic and incidental factors. To study the radionuclide migration in the soil-plant system, an independent statistical index of contamination heterogeneity $H = RAsAp$ is proposed which is calculated as a Brave-Pirsens coefficient of linear correlation between radioactivity of soil and dry biomass of plants grown on it and which allows to determine relative range of contamination that appears in the form of "hot particles". An adequacy of this index is substantiated, and it is used to analyze the experimental results on radionuclide migration.

PT JOURNAL-ARTICLE (ART).

AB A study was made of the influence of high radiation contamination within the ten-kilometer zone of *Chernobyl* disaster on the structure and function of the immune system of (DBA x C57B1)F1 and DBA mice. The cumulative radiation doses with respect to gamma-radiation, were 0.024, 0.168 and 0.336 Gy. T-lymphocyte proliferation was shown to be activated with all radiation doses mentioned above but with doses of 0.024 and 0.168 Gy, helper T lymphocytes, and with 0.336 Gy, suppressor N-lymphocytes were primarily activated. So, in the former case, some effector functions of the immunity were activated, and in the latter, inhibited. It is concluded that certain hyperstimulation of the lymphoid cell formation (including the increase in T-suppressors), that is induced by long-term exposure to low-level radiation, triggers the mechanisms of autonomous regulation of the system that suppress the radiation-induced lymphocyte proliferation and inhibit the effector functions of the immunity. AB The uptake of radiocesium Cs-137 in rabbit's muscle and its clearance were studied following the 24 days long ingestion of hay naturally contaminated as a consequence of the *Chernobyl* accident. The average radioactivity of hay was 2,294 +/- 345 Bq/kg and the daily intake was 0.5 kg. It was found that after 20 days of ingestion the muscle radionuclide concentration equilibrated with that of the feed. The transfer coefficient Tf describing the fraction of the daily intake of Cs-137 found in a kilogram of rabbit's muscle was calculated: $Tf = 0.29 \pm 0.15$ d/kg. The biological Cs-137 clearance rate (after finishing the feeding with contaminated diet) was found to be ruled by two biological half-lives: $Tb1 = 1.5$ days and $Tb2 = 66$ days and fitting the following retention equation: $A_t = 0.66.e^{-0.46.t} + 0.34.e^{-0.01.t}$ It means that 5 days after removing the animals from contaminated diet the amount of Cs-137 can be expected as 30% of the initial one. PT JOURNAL-ARTICLE (ART).
AB The present study concerns the monitoring of children from the
Byelorussian, Ukrainian and Russian republics exposed to the fall-out
of the *Chernobyl* accident. Cytogenetic analyses have been performed
on 41 children coming from different areas and exhibiting varying
amounts of 137Cs internal contamination, as evaluated by whole-body
counter (WBC) analysis. On a total of 28,670 metaphases scored,
radiation-induced chromosome damage is still present, although at a
very low frequency. Due to the very low fraction of dicentrics,
because of the time elapsed from the accident and the relatively low
doses of exposure, radiobiological dosimetry is not possible for
these children. However, considering that the WBC data indicate that
the children are still exposed to 137Cs contamination, the observed
occurrence of stable chromosome rearrangements and breaks may
represent the persisting effect of continuous low doses of radiation.
The present study also indicates that the parallel use of internal
contamination dosimetry and cytogenetics could be usefully employed
to monitor individual exposure to radiation and to define further
management measures. Author-abstract.

AB Radioactive iodine is released at every atomic-bomb testings and
nuclear plants accidents and radioactive iodine is taken up by
thyroid glands (internal radiation). In addition to the internal
radiation, radioactive fallout causes the external radiation and
thyroid glands are known to be sensitive to the external radiation.
Furthermore, patients with radiation-induced thyroid disease can
survive for a long time regardless of the treatment. The survey of
thyroid diseases, therefore, is very sensitive and reliable ways to
investigate the effects of radiation caused by atomic bomb explosion,
testing and various types of nuclear plants' accidents. Our group
from Nagasaki University was asked investigate the thyroid diseases
and joined to the Sasakawa Project. In order to investigate the
effects of radiation on thyroid disease, it is essential 1) to make
a correct diagnosis in each subject, 2) to calculate a correct
radiation dose in each subject and finally, 3) to find out the
correlation between the radiation dose and thyroid diseases including
age-, sex- and area-matched controls. We have established 5 centers
(1 in Russia, 2 in Belarus, 2 in Ukraine) and supplied the most
valuable ultrasonography instruments, commercial kits for the
determination of serum free T4 and TSH level and for the
autoantibodies, instrument for urinary iodine measurements, syringes,
tubes, refrigerators, etc. We visit each center often and asked
peoples at centers to come to Japan for training. Protocol of
investigation is essentially the same as that in Nagasaki, and we are
planning to investigate more than 50,000 children within 5 years. We
are hoping to show a definite conclusion in the near future.(ABSTRACT

PT JOURNAL-ARTICLE (ART).

AB The paper indicates the importance of investigating radionuclide translocation in the human food chain, and the contribution of selected food components in total exposure of the population after accidental radioactive contamination. Data on radioactive contamination and risk assessment of the Croatian population after the *Chernobyl* nuclear accident are given and possibilities of decontamination of food chain components are discussed. Literature data on radionuclide removal from the human food chain are compared to the results of own investigations. Emphasis is placed on biologically most important radionuclides, ^{131}I , ^{90}Sr , ^{137}Cs , and the most effective means of protection are sought. The preventive measures following a nuclear accident should be based on the cost-benefit principle i.e. the damage from applying radiation protection measures should not exceed the benefit from possible dose reduction. SO Radiat-Environ-Biophys. 1993. 32(2). P 137-50.

JT RADIATION AND ENVIRONMENTAL BIOPHYSICS.

PT JOURNAL-ARTICLE (ART).

AB The amount of *Chernobyl-derived* ^{137}Cs transferred to the soil by stemflow, throughfall (precipitation under the tree crown), and leaf-fall from three beeches was investigated as a function of time in the growing seasons of 1991 and 1992. Up to 70 Bq/week was deposited with the stemflow, mainly in dissolved form (< 0.45 micron) rather than in particulate form (> 0.45 micron). The ratio of dissolved radiocesium to particulate radiocesium was about 10 in the stemflow. It varied considerably with time, but since these

variations followed the same pattern for all three trees, they indicated a common cause to be responsible for the fractionation of radiocesium (e.g. meteorological conditions for bark weathering). A significant correlation was observed for the amount of dissolved ^{137}Cs (in Bq) and the amount of stemflow (in liters). The ^{137}Cs concentration in the stemflow (in Bq/l), however, decreased with increasing stemflow intensity (in Bq/week). For particulate radiocesium such correlations were not detected. Up to 5 Bq/m² per week was deposited with the throughfall from the canopy, mainly in particulate form (ratio dissolved radiocesium to particulate radiocesium = 0.34). The mean total annual amounts of ^{137}Cs deposited to the ground (dissolved+particulate) for the three trees were: stemflow: 1991 600 Bq; 1992 460 Bq; throughfall: 1991 and 1992 approximately 100 Bq/m² each; leaf fall: 1992 approximately 10 Bq/m². The data indicate that at present a substantial amount of the radiocesium in the leaves derives already from root uptake. Author-abstract.

SO Health-Phys. 1993 Aug. 65(2). P 141-6.

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB The distribution and the biological half-lives of ^{137}Cs in poultry after continuous intake of foodstuffs contaminated by the *Chernobyl* fallout were studied in order to determine transfer coefficients to yolk, albumen, and shell of eggs as well as transfer coefficients to chicken meat. Mean values for laying hens were found to be 0.2 d kg⁻¹ (whole consumable egg), 1.2 d kg⁻¹ (leg meat), and 1.6 d kg⁻¹ (breast meat) when radiocesium was fed in contaminated grass pellets, and about twice as large i.e., 0.4 d kg⁻¹ (whole consumable egg), 2.8 d kg⁻¹ (leg meat), and 3.0 d kg⁻¹ (breast meat): when radiocesium was fed in contaminated wheat. Reducing effects of the feed additive ammonium-ferric-cyano-ferrate in concentrations of 0.66 g kg⁻¹ of feed mixture on the contamination of hen products were quantified to be a factor of 3 to 4 (whole consumable egg and meat after grass pellet feeding) and 8 to 14 (whole consumable egg and meat after wheat feeding). A drastically higher reduction with an ammonium-ferric-cyano-ferrate dose twice as large (1.33 g kg⁻¹) was achieved. For broiler chickens, activity concentration ratios of meat to feed were derived for various fattening periods, with mean values of about 0.3 (leg), 0.4 (breast), and 0.2 (liver). The addition of ammonium-ferric-cyano-ferrate reduced the activity concentrations in meat by factors of more than 6. Author-abstract.

JT PAEDIATRIC AND PERINATAL EPIDEMIOLOGY.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-LITERATURE (RLT).

AB Studies of the association between the *Chernobyl* accident in April 1986 and reproductive outcome, with particular reference to congenital anomalies, are reviewed. All of the studies so far have been based on the detection of a change in frequency over time. An increased frequency of trisomy 21 in the former West Berlin in January 1987, and increases in the frequency of neural tube defects in several small hospital-based series in Turkey, are not confirmed in larger and more representative series in Europe. No clear changes in the prevalence at birth of anomalies which might be associated with the accident are apparent in Byelorussia or the Ukraine, the republics with the highest exposure to fallout. However, these data are difficult to interpret as the methods of acquisition have not been described and they have not yet been reported in full. Thus, there is no consistent evidence of a detrimental physical effect of the *Chernobyl* accident on congenital anomalies. This is also the case for other measured outcomes of pregnancy. There is evidence of indirect effects--an increase in induced abortions substantial enough to show as a reduction in total births, due to anxieties created. Data are not available on the reproductive outcomes of women pregnant at the time of the accident who were evacuated from the 30 km zone of immediate contamination, of workers in the plant at the time of the accident or of decontamination workers. Moreover, no data are available from several of the other countries closest to the *Chernobyl* area. Author-abstract. 56 Refs.

TI Human uptake of ¹³⁷Cs in mutton.

SO Health-Phys. 1993 Jun. 64(6). P 600-4.

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB The uptake of radiocesium from mutton contaminated by fallout from the *Chernobyl* reactor accident has been studied in eight healthy male volunteers. Each subject consumed, on adjacent days, two meals prepared from the mutton containing a total of 0.8 kBq ¹³⁷Cs. The elevation and subsequent decline in whole-body content were determined from body radioactivity measurements prior to the meals and at intervals up to 15 wk afterwards. Clearance of ¹³⁷Cs between 1 and 15 wk showed a biological half-time of 102 +/- 24 (SD) d, (range 84-154 d). The fraction cleared with this half-time was 80 +/- 4% (range 72-85%). No attempt was made to determine the early retention and excretion but, if the ICRP's assumption of 10% clearance with a 2-d half-life were valid, the data would indicate an average uptake (f₁) of 89%, i.e., marginally lower than the value of 100% assumed in setting limits on intake. TI Ukrainian thyroid doses after the *Chernobyl* accident.

SO Health-Phys. 1993 Jun. 64(6). P 594-9.

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB To estimate thyroid radioactivity in the Ukrainian population from May-June 1986, more than 150,000 individual examinations were carried out by special dosimetric teams. The results of these total measurements were approved to be a basis for assessing individual absorbed doses of infant and adult thyroid irradiation associated with the ¹³¹I exposure. The dosimetric radioiodine data bank of thyroid irradiation of the Ukrainian population was created to

analyze these measurements. The analysis was performed using the data for eight Ukrainian districts and the town of Pripjat, which were all heavily contaminated due to radioiodine exposure. Results of the dose assessments are given using two models: the more conservative model of "single radioiodine intake" and a more realistic model that considers the individual duration of radioiodine intake. In accordance with the more realistic model, the predictions of late effects have shown that a collective thyro-oncogenic dose is equal to 64,000 person-Gy, stimulating the possibility of the emergence of 300 cases (30 incurable) of thyrocancers. Considering this information for the next 35 y (1991-2026), it is possible to predict a 1.4-fold increase over spontaneous thyroid cancer morbidity for children who lived in the heavily contaminated regions of the Ukraine in 1986 (spontaneous and radiogenic to spontaneous).

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB After the *Chernobyl* accident, several radionuclides were deposited on the soil of the Piemonte Region in Italy. Contamination values were monitored and the initial vertical soil profiles of ¹³⁴Cs and ¹⁰⁶Ru were determined. For both radionuclides, more than 60% of the total activity remained in the upper 1-cm layer of soil during the first 7 mo after the accident. The time history of the soil profiles was studied over a period of 3 y in two Piedmontese localities. A compartmental model was also developed to describe downward migration of ¹³⁴Cs and ¹⁰⁶Ru. The results indicated a low mobility for both radionuclides. The change in their vertical profiles may be described using a box model with a transfer constant of 0.2 y⁻¹ for ¹³⁴Cs and 0.3 y⁻¹ for ¹⁰⁶Ru between 1-cm-thick layers. A strong association between the soil fine fraction and the mobility of both radionuclides was also found. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB Within the framework of the "International *Chernobyl* Project," selected areas in the Republics of Ukraine, Belarus, and Russia of the former USSR, contaminated by radioactive fallout from the *Chernobyl* accident in 1986, were investigated by international teams. In addition, environmental studies were carried out in areas officially declared as "uncontaminated regions" in order to corroborate this classification and to provide reference baseline data for the simultaneously performed medical investigations on health effects in the contaminated areas. Altogether, 141 measurements of the gamma dose rate, both outdoors and indoors, were carried out. Also, the radionuclide concentration in 58 soil and food sample was determined. In addition, results from 1,620 individual film dosimeter readings were analyzed. The results show that, in areas adjacent to those officially designated as contaminated regions (¹³⁷Cs surface ground contamination > or = 37 kBq m⁻²), levels of environmental fallout contamination are insignificant. The additional resulting committed effective dose

over the next 70 years due to the fallout is only a fraction of the corresponding value from the natural radiation environment.

TI Caesium radioactivity in several selected species of honey.

SO Sci-Total-Environ. 1993 Mar 25. 130-131. P 95-108.

JT SCIENCE OF THE TOTAL ENVIRONMENT.

PT JOURNAL-ARTICLE (ART).

AB In the years following the accident to the nuclear power plant at *Chernobyl,* investigations on several selected species of honey were done to determine their ^{134,137}Cs contamination. Very low caesium activities were found in flower honeys, especially rape honeys. The transfer factor of caesium from the soil to the rape plant (*Brassica napus* var. *oleifera*) was found to be $f_{Cs} = 0.116 \pm 0.080$ in 1987, but only $f_{Cs} = 0.017 \pm 0.017$ in 1988, due to the lower availability of the caesium by gradual formation of water-insoluble chemical species. Honeydew honeys show a slightly higher ^{134,137}Cs contamination. Honeydew is often produced by lice setting on spruces. Therefore, needles and twigs of spruces (*Picea abies*) were investigated and relatively high caesium contamination was found in fresh needles. A transfer factor for caesium from spruce needles to honeydew honey of about 0.1 was estimated. Finally, the caesium contamination in heather honeys and heather plants (*Calluna vulgaris*) was determined. Surprisingly higher factors between 2 and 40 were obtained for the caesium transfer from soil to *Calluna vulgaris*. These factors give a good explanation for the relatively high caesium contamination of heather honeys. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB T cell number, serum concentrations of thymic hormones and

anti-epithelial autoantibodies were studied in people affected at *Chernobyl* NPP. Group 1 took part in the clearing-up operation and had no clinical manifestations of acute radiation sickness. Group 2 worked at the NPP during the accident; they survived acute radiation sickness (degree I-II, subgroup 2a; degree III-IV, subgroup 2b). The total doses of external radiation were 0.1-0.5 Gy in group 1, up to 4 Gy in subgroup 2a and up to 9 Gy in subgroup 2b. Total T cell number, serum thymic activity and alpha 1-thymosin concentration were decreased in all groups of affected persons. CD8+ cell number decreased only in group 1; CD4+ cell number in subgroup 2b. A decrease in thymic hormone level was most prominent in subgroup 2b. The titres of anti-epithelial antibodies were increased in all groups of affected persons independently of radiation dose. The titres were higher in patients with subnormal levels of alpha 1-thymosin. It has been proposed that radiation alters the function of thymic epithelial cells by direct action and/or through indirect mechanisms including participation of autoantibodies. The observed complex of alterations is similar to that in the normal process of immunological ageing. Author-abstract.

JT PUBLIC HEALTH REPORTS.

PT JOURNAL-ARTICLE (ART).

AB In October 1989, more than 3 years after the nuclear power plant accident at *Chernobyl,* in the Ukraine, the Government of the Union of Soviet Socialist Republics requested that the International Atomic Energy Agency (IAEA) evaluate the medical and psychological health of residents living in areas identified as being contaminated with radioactive fallout. The IAEA designed and conducted a collaborative study to examine whether there were any measurable effects of exposure to the low levels of ionizing radiation resulting from the accident. The study, using structured interviews and IAEA laboratory equipment, collected data on more than 1,350 residents of 13 villages. IAEA clinical staff members concluded that they could not identify any health disorders in either the contaminated or nearby (uncontaminated) control villages that could be attributed directly to radiation exposure. The clinical staff, however, did note that the levels of anxiety and stress of the villagers appeared to be disproportionate to the biological significance of the levels of IAEA-measured radio-active contamination. Almost half the adults in all the villages were unsure if they had a radiation-related illness. More than 70 percent of persons in the contaminated villages wanted to move away, and approximately 83 percent believed that the government should relocate them. The IAEA effort indicates that the

villagers need to be educated about their actual risks, and they need to understand what types of illnesses are, and are not, associated with exposure to radioactive contamination. Unfortunately, the villagers' needs may exceed the available resources of their local and central governments. Author-abstract.

JT ARHIV ZA HIGIJENU RADA I TOKSIKOLOGIJU.
PT JOURNAL-ARTICLE (ART).
AB Measurements of radioactive contamination of cistern waters with
⁹⁰Sr, ¹³⁴Cs and ¹³⁷Cs have been carried out along the Croatian coast
of the Adriatic Sea. An exponential decline of radioactivity
followed the moratorium on nuclear tests. After the nuclear accident
at *Chernobyl*, high radioactivity levels were detected again. The
pre-Chernobyl and the *post-Chernobyl* mean residence times of ⁹⁰Sr in
cistern waters reflect the mechanism by which strontium was released
to the atmosphere (atmospheric nuclear weapon tests conducted in the
stratosphere or explosions in the *Chernobyl* nuclear reactor releasing
radioactive material to the troposphere). For the *pre-Chernobyl*
period, the mean residence time of ⁹⁰Sr in cistern waters was similar
to that calculated for fallout, being approximately 10 years. The
post-Chernobyl ¹³⁷Cs/⁹⁰Sr activity ratio has been decreasing, but it
has not yet reached the *pre-Chernobyl* values (approximately 1.6).
The time-dependent ¹³⁴Cs/¹³⁷Cs activity ratio reflects the *Chernobyl*
reactor inventory of these radionuclides. The annual dose for the
critical adult population received from ⁹⁰Sr, ¹³⁴Cs and ¹³⁷Cs by
consumption of cistern water was estimated to be a few percentages of
the dose from natural background radiation. Author-abstract.

SO Przegl-Epidemiol. 1992. 46(3). P 273-6.

JT PRZEGLAD EPIDEMIOLOGICZNY.

PT JOURNAL-ARTICLE (ART).

AB The scope of this report is the incidence of goiter in school
children living in Mielec and neighbouring villages. We examined a
group of 3537 children aged 6-14. The enlargement of thyroid gland
was observed in 49.3% of the population. Judging by the results of
the research this region can be regarded as endemic. There might be
several reasons for a high incidence of goiter in this region. The
most important are: insufficient iodine prophylaxis, pollution of the
environment including the pollution with radioiodine after the damage
of the *Chernobyl* reactor. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB The concentrations of ¹³⁷Cs and ¹³⁴Cs in dirt deposits on the roofs
of buildings are much higher than those in the surface of soil at
ground level. Thus dirt on roofs concentrates radioactive cesium in

fall-outs. The ^{137}Cs concentration in dirt deposits on the roofs of older buildings is not consistently higher than that on the roofs of new ones, but the $^{137}\text{Cs}/^{134}\text{Cs}$ ratio is higher in deposits on older buildings constructed before the first half of the 1970s, and decreases exponentially with decrease in age of the buildings gradually reaching 1.9 ± 0.2 , the value in the air-borne dust at the time of the *Chernobyl* accident. From this relationship, the contribution of *Chernobyl* radioactivity to accumulated ^{137}Cs was calculated as 32% on buildings constructed in 1962. The radioactive cesium concentrations in dirt deposits in gutters of private houses and on the roofs of university buildings in Japan were also determined. Author-abstract.

TI Radioactive contamination of the Adriatic Sea by ^{90}Sr and ^{137}Cs .

SO Health-Phys. 1993 Feb. 64(2). P 162-9.

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB Results of systematic long-term measurements of ^{90}Sr and ^{137}Cs in surface seawater, performed at four locations along the Croatian coast of the Adriatic Sea, are summarized. Observed trends in annual mean activity concentrations are discussed. ^{90}Sr and ^{137}Cs fallout activities affect seawater activity, the coefficient of correlation between ^{90}Sr fallout activity and ^{90}Sr seawater activity being 0.72. No significant variations of ^{90}Sr mean residence time in the sea-mixed layer on different locations were found. From 1978-1985, the $^{137}\text{Cs}:^{90}\text{Sr}$ activity ratio in seawater was 1.52 ± 0.40 . In May 1986, as the consequence of the *Chernobyl* nuclear accident, this ratio increased to 92.4 ± 58.2 . Author-abstract.

TI ^{137}Cs concentration in soil, prairie plants, and milk from sites in southern Chile.

SO Health-Phys. 1993 Feb. 64(2). P 157-61.

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB Soil, prairie plants, and milk samples were collected at 39 dairy farms in the 9th and 10th Region in Southern Chile (38 degrees 44'-41 degrees 08' S) between 1982 and 1990. ^{137}Cs concentrations found in soil, plant, and milk samples ranged from 3.8-17.1 Bq kg⁻¹ for soil, from < 0.3-20 Bq kg⁻¹ dry mass for plants, and from 0.10-0.71 Bq kg⁻¹ for milk. Cesium concentration levels resulting from soil sample measurements exhibit a close similarity with corresponding values found in soils from Central Europe before 1986. The concentration

ratio prairie plants:soil ranged from 0.05-0.62, 0.52-5.0, and < 0.02-0.40 corresponding to Dystrandepths, Placandepths, and Palehumults soil groups, respectively. At seven selected dairy farms in the vicinity of Valdivia city (10th Region), soil, prairie plant, and milk samples were taken yearly during the grazing period between 1982 and 1990. Results obtained from soil samples taken after April 1986 show no significant increase of the ¹³⁷Cs concentration. Concentrations in plants and milk for ¹³⁷Cs decreased during the observation time. ¹³⁴Cs (as an indicator of *Chernobyl* fallout) was not found in soil, plant, or milk samples during 1986-1990. JT INTERNATIONAL JOURNAL OF RADIATION BIOLOGY.
PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).
AB The *Chernobyl* nuclear reactor accident in Russia in 1986 has further revealed the susceptibility of the environment to radioactive contamination. This can have serious implications for the safety of milk as well as other foods. Global fallout and other isotope releases can threaten to increase the radionuclide levels in milk alarmingly, and thus make it unfit for human consumption. Perception of such fears in the past resulted in considerable research efforts being directed towards radioactive decontamination of milk by different means. The holding of milk and milk products long enough to deactivate certain radioisotopes prior to consumption, conversion of milk into butter, and manufacturing cheese by using modified processes are some of the approaches in minimizing the radioactivity risk to consumers. Extensive studies carried out in the USA have shown that though somewhat expensive, ion-exchange treatment of milk in large-scale, automated plants can eliminate 90% or more of the radionuclides of concern, i.e. strontium-90, and iodine-131, and much of caesium-137. Various factors affecting the efficiency of the ion exchange process and properties of the treated milk are reviewed. Other processing techniques such as electrodialysis are also briefly discussed in relation to removal of radionuclides from milk. Author-abstract. 53 Refs.

JT INTERNATIONAL JOURNAL OF RADIATION BIOLOGY.

PT JOURNAL-ARTICLE (ART).

AB We have shown elsewhere that highly non-uniform exposure to ionizing radiation from authentic *Chernobyl-released* and artificially-produced hot particles (fragments of nuclear fuel) transform fibroblastic 10T1/2 cells in vitro effectively. We have also shown that hot-particle exposure leads to mutation and overexpression of the tumour suppressor gene p53 (and some other growth-related genes) in mouse skin in vivo at a high frequency. In the present paper it is shown that hot-particles produced by irradiating natural uranium with slow neutrons, when implanted (immobilized) under the skin of hairless and nude mice, induce epidermal tumours in excess compared with the conventional non-threshold stochastic model of radiation-induced cancer. One explanation for the effectiveness of the hot-particle exposure, under the present assay conditions, is that the same cells in which specific radiation-induced DNA damage is most likely to occur, are forced into sustained mitotic activity in the chronic wound which develops around the radiation source (combined genotoxic and nongenotoxic effects). The results are consistent with a role for cell proliferation in multistage carcinogenesis in mouse skin. Author-abstract.

SO Int-J-Radiat-Biol. 1993 Mar. 63(3). P 361-7.

JT INTERNATIONAL JOURNAL OF RADIATION BIOLOGY.

PT JOURNAL-ARTICLE (ART).

AB Eight 'rogue' lymphocyte metaphases containing a large number of aberrant chromosomes were noted during a survey of chromosomal damage in 328 Belarussian children. The study population comprised children of families living in territory contaminated by radiation from the *Chernobyl* accident. The majority of the sample had been evacuated within 1 week from very heavily polluted territory to areas that had received much less fallout. Two hundred cells were scored per subject and one rogue cell was found in a child exposed in utero; one in a child conceived after the accident and six in the postnatally exposed group. The possibility that the damage was due to exposure to radio-iodine concentrated in the thyroid gland, or to radiation from incorporated 'hot particles' of an alpha or beta/gamma emitter is discussed. It is concluded that the damage to these cells is unlikely to have been caused by radiation. Author-abstract.

from eastern Europe, Sweden, and North America.

SO Appl-Environ-Microbiol. 1993 Jan. 59(1). P 134-9.

JT APPLIED AND ENVIRONMENTAL MICROBIOLOGY.

PT JOURNAL-ARTICLE (ART).

AB A comparison was made of ¹³⁴Cs and ¹³⁷Cs contamination in fungi from eastern Europe and eastern North America. Mean activities of 25 Ukrainian, 6 Swedish, and 10 North American collections were 4,660, 9,750, and 205 Bq/kg (dry weight), respectively. Additional measurements were made on samples from the Moscow, southern Belarus, and Yugoslavia/Bulgaria regions. Activity values were found to vary by several orders of magnitude within all geographic areas, even for the same mushroom species. Significantly higher specific activities were observed in mycorrhizal species than in saprophytic and parasitic fungi. Unfortunately, many of the European mycorrhizal species considered as prized edibles contained unacceptably high levels of ¹³⁷Cs (> 1,000 Bq/kg dry weight) and should be used sparingly as food. By contrast, no mushrooms collected in Ontario or northern Michigan exceeded 1,000 Bq of ¹³⁷Cs per kg (dry weight). The excessive ¹³⁷Cs contamination was evident in mushrooms from areas that had substantial fallout from the 1986 accident in reactor 4 at the *Chernobyl* nuclear power station. However, observations suggest that about 20% of the ¹³⁷Cs in eastern Europe (Moscow area, Belarus, and Ukraine) is of *non-Chernobyl* origin. Author-abstract.

TI Changing trend of neural tube defects in eastern Turkey.

SO J-Epidemiol-Community-Health. 1993 Feb. 47(1). P 40-1.

JT JOURNAL OF EPIDEMIOLOGY AND COMMUNITY HEALTH.

PT JOURNAL-ARTICLE (ART).

AB STUDY OBJECTIVE--The aim was to study the relationship between birth prevalence of neural tube defect (including anencephaly) in Eastern Turkey before and after the *Chernobyl* disaster. DESIGN--This was a prospective study of time trends in live births and stillbirths over the years 1985-1990. Medical and sociodemographic data were recorded for the mothers. SETTING--Elazig, Eastern Turkey. SUBJECTS--There were 5240 live births and stillbirths during the study period, 24 of whom had neural tube defect and of these 20 had anencephaly. MAIN RESULTS--Of the 5240 newborns, 24 had a neural tube defect, giving a birth prevalence of 4.5 per 1000 total births. Of these, 20 were anencephalic (3.8 per 1000). In all, of the 2355 conceptions estimated to have occurred prior to the *Chernobyl* disaster in May 1986, the birth prevalences of total neural tube defect and anencephaly were the same (1.7 per 1000). This contrasts with the years following after *Chernobyl*, when the birth prevalence of total neural tube defect was 6.9 per 1000 (5.5 per 1000 for anencephaly). The differences were statistically significant ($p < 0.001$). These two increased rates reached a peak of 12.4 (for total neural tube

defects) and 8.9 (for anencephaly) in 1988. In 1989 the rate of total neural tube defects decreased to 10.0 and that of anencephaly to 8.6 per 1000. In 1990 the rate of total neural tube defects fell to 5.6 and that of anencephaly fell to 4.2. CONCLUSIONS--The changes in birth prevalence of neural tube defects might be due to the *Chernobyl* disaster. However, the increases observed occurred mainly in infants conceived well over a year after the *Chernobyl* disaster, suggesting that other factors may be responsible. Author-abstract.

TI ECOSYS-87: a dynamic model for assessing radiological consequences of nuclear accidents.

SO Health-Phys. 1993 Mar. 64(3). P 232-52.

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB The time-dependent radioecological simulation model ECOSYS-87 has been developed to assess the radiological consequences of short-term depositions of radionuclides. Internal exposure via inhalation and ingestion, as well as external exposure from the passing cloud and from radioactivity deposited on the ground, are included in the model. The site-specific parameter values of the model are representative of Southern German agricultural conditions; however, the model design facilitates adaption to other situations. The ingestion dose is calculated as a function of time considering 18 plant species, 11 animal food products, and 18 processed products. The ingestion and inhalation exposure is estimated for six age groups using age-dependent consumption and inhalation rates and age-dependent dose factors. Results demonstrate a pronounced influence regarding the time of year (season) of deposition on the ingestion dose and on the relative importance of the exposure pathways. Model results compare well with activities in foods measured after the *Chernobyl* accident. Author-abstract.

SO Int-J-Radiat-Biol. 1992 Dec. 62(6). P 729-33.

JT INTERNATIONAL JOURNAL OF RADIATION BIOLOGY.

PT JOURNAL-ARTICLE (ART).

AB The combined effects of whole-body radiation and localized radiation trauma have received scant experimental attention. However, in the recent accidents at *Chernobyl* and Goiania skin damage from beta-contamination was combined with total-body radiation and in many cases the skin lesions which covered large surfaces of the body were severe and recovery was prolonged. This paper models the immunosuppressive effects of whole-body gamma-radiation in the sublethal to lethal range (1-11 Gy) on the skin reactions produced by 50 Gy of superficial beta-radiation. For gamma ray doses < 4 Gy no synergistic effects were detectable. For gamma-ray doses of 4, 6 and 8 Gy there was a 4-5-day prolongation in time-course of the skin reaction but no significant exacerbation of its severity. The overall time for the resolution of the skin reaction (45 days) was also unaffected by the relatively high whole-body doses. These rather surprising findings of minimal synergy between whole-body exposure and a localized severe beta burn to the skin are perhaps explained by the mismatch between the maximal immunosuppression at 2-10 days postirradiation and the timing of the skin damage at 10-25 days. PT JOURNAL-ARTICLE (ART).

AB The incidence as well as age, seasonal and breed distribution of canine mammary tumours (n = 521) were studied at the Clinic of Obstetrics and Gynaecology of the University of Veterinary Science, Budapest, between 1985 and 1989. In 39 cases of mammary tumour, blood plasma oestradiol (E2) and progesterone (P) concentrations were

also determined. Of all dogs referred to the clinics of the University in 1985, 0.7% had mammary tumour. On the average, 104 +/- 9.3 cases of mammary tumour were recorded at the Clinic of Obstetrics per year. This number did not increase after the *Chernobyl* atomic reactor catastrophe of 1986. The age distribution of canine mammary tumour found in this study shows good agreement with earlier data of the literature: mammary tumour showed the highest incidence in 10 years old dogs. The incidence of mammary tumour kept increasing with age until the 14th year of life (as expressed in per cent of animals of identical age). The number of mammary tumours was markedly higher in the spring (April-May) and autumn (September). This seasonality was demonstrable in 11 to 16 years old bitches, too. On the basis of the blood plasma E2 and P profiles, 61.5% of the clinically anoestrous animals were found to be cycling. The strikingly high ratio of pulis among dogs with mammary cancer was suggestive of a breed disposition. Author-abstract.

SO Genetika. 1992 Sep. 28(9). P 49-57.

JT GENETIKA.

PT JOURNAL-ARTICLE (ART).

AB Four male mice were shown to have decreased fertility among 74 laboratory male mice exposed in the *Chernobyl* APP area during embryogenesis. Electron microscopic analysis of synaptonemal complexes (SC) of at zygotene-diplotene and light-optic analysis of chromosome aberrations at diakinesis-metaphase 1 demonstrated the

presence of interchromosome translocations in autosomal chromosomes, and also intrachromosome translocations in two of four animals. The frequency of chromosome translocations in SC preparations was on the average 1.8 times higher than their frequency at the diakinesis-metaphase 1 stage. High percentage of cells in which associations of sex bivalent axes (XY) with the axes of autosomal bivalents were observed in the SC preparations and reduced fertility in the animals studied confirmed the Forejt's hypothesis that such associations caused the arrest of cells at pachytene and, as a consequence, disturbed the process of embryogenesis.

JT MEDICINA DEL LAVORO.

PT CLINICAL-TRIAL (CTR). JOURNAL-ARTICLE (ART).

AB Ionizing radiations (IR) produce changes in the eye and, above all, in the lens. Several studies on radiotherapy in neoplastic diseases and dangerous nuclear accidents like *Chernobyl* have indicated the percentage and the exposure level at which the eye becomes the target organ of IR. The aim of the study was to establish the association between ocular tension and low-level IR exposure. The incidence of ocular hypertension in the general population is about 1-2% in persons aged 30-40 years and 10% in the 70-80 years age group; the frequency of glaucoma is 0.2-0.5% in persons aged 50-55 years and 2% in those aged 70 years and over; after 15 years of disease, conversion from ocular hypertension to glaucoma is observed in 40% of the cases. We examined 128 subjects occupationally exposed to IR (42 radiologists and 86 radiology technicians) and 130 non-exposed. For each subject we recorded age, length of employment, job titles, dosimetry, ocular tension, refraction and motility impairments. The data obtained from a complete ophthalmologic test was analyzed by the t-Student test, Chi-square and Pearson's test. The ocular tension of 33 occupationally exposed subjects and 2 non-occupationally exposed subjects was higher than the cut-off value of 18 mmHg. There was no analogy between age distribution of ocular hypertension in the groups under study and the general population. There seems to have been a relationship between ocular tension and job titles since a higher incidence was observed among the radiology technicians than among the radiologists and also in the 30-40 years age class.(ABSTRACT TRUNCATED AT 250 WORDS). PT JOURNAL-ARTICLE (ART).
AB Recently, an impressive increase in malignant thyroid tumours has
been observed among children less than 15 years of age living in the
Republic of Belarus at the time of the nuclear accident of *Chernobyl*
in 1986. More than half of these patients lived in the region of
Gomel, nearest to *Chernobyl.* Because of the very short time interval
between the accident and the tumour occurrence an independent review
of the available histopathological material was done. Out of 101
cases diagnosed as thyroid cancers, we reviewed slides of 93 cases
and agreed the diagnosis of malignancy in 92.5%. Of these tumours
96.5% were papillary carcinomas, 61.5% were moderately or poorly
differentiated. Extrathyroidal extension was observed in 60.5%,
regional lymph node metastases in 74% and distant metastases in 7%.
One of the patients died from lung metastases. Our results confirm
that the neoplasms increasingly diagnosed between 1986 and 1991 among
children of this region are thyroid carcinomas. In addition, we
correlate several histopathological findings with sex and age of the
patients and other parameters, and compare the results with data from
other studies. Author-abstract.

SO Sci-Total-Environ. 1992 Jun 30. 121. P 109-31.

JT SCIENCE OF THE TOTAL ENVIRONMENT.

PT JOURNAL-ARTICLE (ART).

AB Relatively little attention has been given to the long term prospect of fluvial transport processes redistributing *Chernobyl-derived* radiocaesium within the UK. Work undertaken within the Wye basin, central Wales, demonstrates a complex distribution of fallout at the catchment scale, with the bulk of the deposition concentrated in a narrow north-south band, situated in the west central areas of the basin, which contained in excess of 1500 Bq m⁽⁻²⁾ of (134)Cs. Fluvial transport and redistribution of this material was demonstrated by river sampling during the winter of 1988/89, when the radiocaesium content of suspended sediment transported by the River Wye (approximately 30-50 mBq g⁽⁻¹⁾ of (137)Cs) remained 3-5 times higher than *pre-Chernobyl* levels. Floodplain reaches displayed variable levels of secondary contamination, dependent upon the upstream supply of radiocaesium and local morphological controls. Accordingly, the highest (134)Cs inventories within the basin (> 6000 Bq m⁽⁻²⁾) were associated with rapidly accreting floodplain sites. A number of these sites experienced only limited amounts of direct atmospheric fallout. The importance of fluvial redistribution as a secondary contamination mechanism is thus highlighted.

AB OBJECTIVES: We analyzed the influence of the radioactive fallout
after the *Chernobyl* disaster on the rate and regional distribution of
birth defects and abortion rates in southern Austria. STUDY DESIGN:
During 1985 to 1989 a total of 66,743 births was monitored. Twelve
sources provided data on 1695 cases of birth defects, 1579 of which
were suitable for analysis. All cases were analyzed in terms of
their calculated conception date and divided into three main groups
according to their vulnerable phase of embryogenesis,
spermatogenesis, and oogenesis. To study possible regional changes,
the findings were plotted in 17 political subdistricts. The overall
abortion rate and the counseling frequency at termination clinics was
determined. RESULTS: No significant changes in the incidence of
birth defects, abortion rate, or counseling rate at pregnancy
termination clinics were observed. CONCLUSIONS: Assessing the
teratologic potential of low-dose radiation is difficult and requires
adequate grouping of birth defects, sufficient baseline data, and
highly reliable registries. Author-abstract.

AB In Norway, external doses of radiation resulting from fallout from
the *Chernobyl* nuclear accident were estimated from detailed
measurements, including soil deposition patterns. Internal doses
were estimated from measurements of radioactive cesium in meat and
milk supplies. The doses were calculated as average monthly doses
for each of 454 municipalities during 36 consecutive months after the
accident in spring 1986. Prospectively collected data on all
newborns listed in the Medical Birth Registry of Norway who were
conceived in the period May 1983-April 1989 were used to assess
possible dose-response relations between estimated external and
food-based exposures and congenital malformations and some other
conditions. A positive association was observed between total
radiation dose (external plus food-based) and hydrocephaly, while a
negative association was observed for Down's syndrome. However, an
important conclusion of the study was that no associations were found

for conditions previously reported to be associated with radiation, i.e., small head circumference, congenital cataracts, anencephaly, spina bifida, and low birth weight. Potential sources of bias, including exposure misclassification and incomplete ascertainment of cases, are discussed. Author-abstract.

SO Sci-Total-Environ. 1992 May 1. 116(1-2). P 93-107.

JT SCIENCE OF THE TOTAL ENVIRONMENT.

PT JOURNAL-ARTICLE (ART).

AB Depth profiles of radiocesium were measured in a podsollic parabrown earth of a spruce stand and in a podsol of a pine stand up to 3 years after the *Chernobyl* accident. At the same sites undisturbed soil columns of 20 cm diameter and 40 cm length were taken, transferred to the laboratory and irrigated intermittently with synthetic rainwater containing initially a known amount of radiocesium. The resulting migration of radiocesium in the columns under unsaturated conditions was determined as a function of time up to 3 years with a scanner

technique. The depth profiles of radiocesium observed in the field and in the columns were evaluated with a compartment model to obtain the residence half-times of this radionuclide in the various soil horizons. The field observations yielded a residence half-time in the organic layer of both soils of approximately 4-6 years for *Chernobyl-derived* cesium, and of 10-15 years for cesium from the global fallout of weapons testing. In the mineral soil (0-5 cm), under spruce the residence time of *Chernobyl-derived* cesium was 15 years, that of cesium from the global fallout (present in the soil since approximately 30 years) was 50 years. Under pine, the residence time in the mineral soil was 4 years for *Chernobyl-derived* cesium and 11 years for global fallout cesium. Obviously, in each layer of both soils cesium becomes less available for migration with time. The residence times of radiocesium evaluated from the column experiments were in good agreement with those obtained from the field observations. Due to the comparatively short duration of the column experiments, however, the long-term increase of the residence time of radiocesium in the soil was not yet unambiguously observable.

PT JOURNAL-ARTICLE (ART).

AB This paper presents results of the research on the mutagenic effect
of ambient air in the Cracow area. Initial studies were conducted in
May 1986, following the *Chernobyl* accident. Other studies were
performed at various sites within the Cracow area in the Spring of
1987. Counts were made of stunted hairs and pink cells in the stamen
hairs of Tradescantia clone 4430. Mutations scored from the 11th day
after the beginning of exposure were used as a measure of the
mutagenic effect. The mean mutation frequencies measured in 1986 and
1987 were 0.43 and 0.21 per 100 hairs respectively. The
time-dependent development of mutation frequencies observed after the
Chernobyl accident showed a correlation with the time-dependent
development of total radioactivities measured in the air at that
time. The results obtained in 1987 showed on average a significant
decrease of ambient air mutagenicity. Still, the variation of
mutation rates observed during the investigated period at different
sites in the Cracow area was rather high (0.09-0.38 mut/100 hairs).
Only the highest frequencies observed in the Spring of 1987 were
comparable to the level detected after the *Chernobyl* accident.

PT JOURNAL-ARTICLE (ART).

AB The content of large intestine has been studied in persons exposed to
radiation injury in consequence of the accident at the *Chernobyl*

Atomic Power Plant. It is stated that bifidobacteria (10(7)-10(10) cells in 1 g of feces) prevailed (as in healthy people), Bifidobacterium indicum being a dominating species. Amount of lactic-acid bacteria in 1 g of defecations of examined patients was within the range of 10(6)-10(9) cells and in certain persons it reached 10(10) cells (primarily fecal Enterococci). A considerable amount of patients with acute radiation sickness of the 3d degree had in their intestine 10(9)/g of lactic-acid bacteria, Lactobacillus casei and L. plantarum prevailing there. The frequency of yeast isolation from defecations of patients constituted 83%, while the number of cells in 1 g of feces--from 10 to 10(4). Yeast of the Candida genus, mainly Candida parapsilosis, prevailed. The species composition of isolated microorganisms has no substantial differences from microocenosis of healthy people. The content of intestine of persons suffered from radiation is characterized only by greater amount of lactic-acid bacteria and enterococci as compared with healthy adults. Author-abstract.

AB Several radionuclides were identified in the surface air in Finland following a nuclear incident in Sosnovyy Bor on 24 March 1992. In addition to gases, the release contained small uranium fuel particles. The radionuclide concentrations were of the same order of magnitude as the concentrations detected in Northern Finland in 1987 after the nuclear explosion in Novaya Zemlya (1 mBq m⁻³) but five orders of magnitude smaller than the concentrations during the *Chernobyl* accident in 1986. The radiological consequences in Finland were insignificant. However, studies show that even a minor release, across the sea and more than 100 km away, can be detected and important information, including the time of the incident and the composition of the release and the burn-up of the damaged fuel, can be revealed by the most accurate radioactivity measurements.

PT JOURNAL-ARTICLE (ART).
AB The birth of industrial society produced demand for the services of professionals specialized in matters related to industrial safety. Three professions--safety engineering, industrial medicine, and ergonomics--are examined. These professions are observed to either submit to single sets of demands, to integrate contradictory demands, or to experience scission. Until the late 1960s their growth appears to have been relatively peaceful and uncontroversial. From this period onward, controversy breaks out over questions related to industrial safety, and professions and government administrations grow. Increasingly, the traditional approach of safety professionals is called into question, and they adopt new orientations. These changes are mapped through the examination of data drawn principally from the United States, France, Great Britain, and to a lesser extent Brazil. The traditional standards approach competes with cost-benefit analysis and with systemic safety for influence; in addition, an emergent approach that analyzes accident causes in terms of social relations of work is detected. From Bhopal to *Chernobyl*, new technologies subject civilian populations to risks of catastrophic accidents, and the action of safety professionals comes under the spotlight. The analysis constructed permits new understandings of the past and the future of these professions.

AB Dietary studies and whole-body measurements were used to estimate the intake of radiocesium and the radiation dose received by different groups of people in Norway after the *Chernobyl* accident. Freshwater fish, milk, and reindeer meat were the major sources for radiocesium intake. Dietary advice, together with agricultural decontamination measures, resulted in a considerable reduction in the exposure level of the population. A majority (40-80%) of the specially selected groups (farmers-hunters and Sami reindeer herdsman) changed its diet significantly after the accident. Without dietary changes, specifically a reduction in the consumption of freshwater fish and reindeer meat, the Sami group would have had a 400-700% higher radiocesium intake, and the farmers-hunters' intake would have been up to 50% higher than what they actually had experienced. TI Behaviour of long-lived *Chernobyl* radionuclides in a soil-water system.

SO Analyst. 1992 Jun. 117(6). P 1041-7.

JT ANALYST.

PT JOURNAL-ARTICLE (ART).

AB Field and laboratory experiments have been used to study the behaviour of long-lived radionuclides in the zone affected by the *Chernobyl* accident. Speciation of ⁹⁰Sr and ¹³⁷Cs in soils and bottom sediments was determined. The principal distinction of the *Chernobyl*

fallout was that it contained a relatively small proportion of exchangeable forms because a considerable fraction of the radionuclides was incorporated as part of the insoluble fuel particles. Disintegration of fuel particles in soils and bottom sediments results in transition of non-exchangeable forms into exchangeable forms. Radionuclide species have different pathways and rates of migration in soils and bottom sediments. Migration of each chemical form was described by a convective-dispersive equation taking into account transformation processes of radionuclide species in soils or bottom sediments. Adsorption of ^{90}Sr and ^{137}Cs in the environment is controlled by the cation-exchange capacity and the selectivity of the solid phase (i.e., soil, bottom sediments and suspended matter) and the cationic composition of the liquid phase (i.e., soil solution, surface run-off and river or lake water). The corresponding parameters for the processes were obtained.

TI `Radionuclide transfer by migratory birds:.

SO Radiobiologiya. 1992 May-Jun. 32(3). P 357-63.

JT RADIOBIOLOGIYA.

PT JOURNAL-ARTICLE (ART).

AB Evaluation of the zoogenic transfer of radionuclides from the 30-km zone around the *Chernobyl* NPP was necessary because of the enormous heavily polluted territory and mighty flow of migratory birds who tended to large rivers, the Dnieper and Pripjat. The integral estimate of the transferred amount was obtained as a product of three variables: the transfer factor ($0.0077 \text{ m}^2/\text{kg}$ for ^{137}Cs ; $0.0107 \text{ m}^2/\text{kg}$ for ^{90}Sr), the density of birds ($0.002 \text{ kg}/\text{m}^2$, at the mass of migrants about 5000 t per year), and the total fund of radionuclides throughout the territory. The upper estimated limit of the annual transfer rate was 5.5 Ci ($2\text{E} + 11 \text{ Bq}$) for ^{137}Cs and 1.8 Ci ($6.7\text{E} + 10 \text{ Bq}$) for ^{90}Sr . Restrictions of hunting are recommended within the northern part of the Kiev reservoir. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB A group of liquidators and patients survived acute radiation sickness

(ARS) was studied five years after the effect of radiation factors resulted from the *Chernobyl* A.P.S. disaster. Studied were the number of T-lymphocytes (SD2+, SD3+, SD5+), subpopulations SD16+ and SD25+, the content of SD16+ and SD25+ lymphocytes and B-cells, as well as the levels of serum IgM, A, G; determined was the concentration of serum alpha 1-thymosin. A decrease was noted in the number of T-cells of the examined patients, with respect to all markers studied: the number of SD4+ cells was found decreased in patients with ARS sequelae and normal in liquidators. The decrease in serum alpha 1-thymosin was a function of dose. Dynamics of changes in the T-cells of the examinees may reflect the new trends in the radiation response of T-lymphocytes which were not directly related to initial damages to the latter. The injury to the stroma of the thymus and especially to its epithelial cells may be the basis for later postirradiation damages to the immune system. The decrease in the concentration of alpha 1-thymosin in the blood serum of the examinee is the manifestation of the thymus hypofunction. In liquidators and patients with the ARS sequelae the number of SD25+ cells increased markedly indicating the existence of the source of endogenous cell activation. The content of B-lymphocytes in all studied groups of patients was reduced which may serve as a criterion of chronic stress. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB A group of patients, suffering from sequelae of acute radiation sickness (ARS), and liquidators was studied 5 years after exposure to a complex of factors resulting from the *Chernobyl* A.P.S. disaster. Studied were: the antibody titres to antigens of the cytoplasm of thymus epithelial reticulum cells and to Hassall's corpuscles the levels of serum immunoglobulins M, G, A; and the content of serum alpha 1-thymosin. Patients with ARS sequelae and liquidators showed a high level and incidence of autoantibodies to antigens of cytoplasm of thymus epithelial reticulum cells and to Hassall's corpuscles. There were no significant differences between the antibody levels in the blood of patients with ARS sequelae and liquidators. The antibodies were found to belong to IgM class; there was a correlation between the serum IgM titres and the rate of the indirect immunofluorescence reaction with autoantibodies to antigens of the cytoplasm of the thymus epithelial reticulum cells. To identify autoantibodies cryostat sections of human and mouse, (CBA x C57BL/6) F1, thymus as well as the epithelial and stromal cell culture of

mouse thymus can equally be used. Author-abstract.

TI "Rogue" lymphocytes among Ukrainians not exposed to radioactive
fall-out from the *Chernobyl* accident: the possible role of this
phenomenon in oncogenesis, teratogenesis, and mutagenesis.

SO Proc-Natl-Acad-Sci-U-S-A. 1992 Aug 1. 89(15). P 6973-7.

JT PROCEEDINGS OF THE NATIONAL ACADEMY OF SCIENCES OF THE UNITED STATES
OF AMERICA.

PT JOURNAL-ARTICLE (ART).

AB Cultured lymphocytes exhibiting extreme cytogenetic damage (rogue
cells) were observed in preparations from 8 of 24 individuals sampled
in Krasilovka, a Ukrainian village receiving little or no increased
radiation after the *Chernobyl* disaster, but were not observed in an
additional 24 persons from two Russian towns in the more contaminated
area. This observation cements the worldwide occurrence of these
cells. The present data plus a review of the literature establish
that rogue cells appear in brief bursts simultaneously in certain
individuals of discrete populations. We suggest that the pattern is
consistent with the action of a viral trigger that acts directly or
indirectly--the latter possibly through the activation of latent

chromosomal retroposons. If this phenomenon occurs in other tissues, it may have important implications for oncogenesis, teratogenesis, mutagenesis, and evolution. Author-abstract.

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB On the basis of experimental data on the fallout of ¹³⁷Cs from the *Chernobyl* accident, a statistical analysis was made of possible values of the coefficients of transfer via the soil-grass pathway. Model calculations of the possible radionuclide concentration in milk are performed by the Monte Carlo method using the probability distribution function obtained. It is shown that not only our limited knowledge and the possible diversity of the external conditions, but also the very nature of the phenomenon under consideration, make it desirable to switch from a deterministic to a stochastic formulation of the model. The fact that the dependence of the soil-to-grass radionuclide transfer coefficients on the initial concentration in soil might be non-linear in character is an indication of the limitation of the conventional linear model. PT JOURNAL-ARTICLE (ART).

AB Our objective was to explore whether the radiation fallout in Finland after the accident at the *Chernobyl* nuclear power plant in April 1986 led to an increased incidence of trisomy 21. In this geographic and temporal cohort study, the country was divided into three zones according to the amounts of radioactive fallout and internal radiation caused by two cesium isotopes. The 518 cytologically verified cases of trisomy 21 were divided into a control group (conceived before the accident), and a study group of children whose expected dates of birth were in the post-accident years 1987-1988, i.e., pregnancies commenced after May 1986. The cases were also divided into three subgroups according to the zones of radiation. There were no significant differences in prevalence of trisomy 21 between the control and study groups nor between the three zones in spite of the significant differences in the levels of radiation and in the body burden that prevailed throughout the study period. Power estimates showed that in the two zones of lower radiation, an increase of 0.5% in the prevalence would have been detected with a power of 0.85, and in the somewhat smaller zone of the highest radiation, with a power of 0.70. The study lends no further support to the view that the low radiation fallout in western Europe would have been causally associated with trisomy 21. Author-abstract.

JT SCIENCE OF THE TOTAL ENVIRONMENT.

PT JOURNAL-ARTICLE (ART).

AB The sources of *Chernobyl-derived* caesium concentrations in air and deposition samples collected from mid-1986 to the end of 1990 at Munich-Neuherberg, Germany, were investigated. Local resuspension has been found to be the main source. By comparison with deposition data from other locations it is estimated that within a range from 20 Bq m⁻² to 60 kBq m⁻² of initially deposited ¹³⁷Cs activity approximately 2% is re-deposited by the process of local resuspension in Austria, Germany, Japan and the United Kingdom, while significantly higher total resuspension is to be expected for Denmark and Finland. Stratospheric contribution to the present concentrations is shown to be negligible. This is confirmed by cross correlation analysis between the time series of ¹³⁷Cs in air and precipitation before and after the *Chernobyl* accident and the

respective time series of cosmogenic ⁷Be, which is an indicator of stratospheric input. Seasonal variations of caesium concentrations with maxima in the winter months were observed. Author-abstract.

TI Thyroid nodules in the population living around *Chernobyl.*

SO JAMA. 1992 Aug 5. 268(5). P 616-9.

JT JAMA.

PT JOURNAL-ARTICLE (ART).

AB OBJECTIVE--To determine the baseline incidence, prevalence, and characteristics of thyroid nodules in the population living around the *Chernobyl* nuclear power plant and to compare the findings with unexposed populations. DESIGN--Prevalence study. Population samples from seven highly contaminated villages were compared with six nearby control villages of the same size and type. The data were obtained as part of the International *Chernobyl* Project conducted in 1990. SETTING--The study was conducted 4.5 years after the *Chernobyl* reactor accident that released large quantities of radionuclides, including radioiodine. PATIENTS OR OTHER PARTICIPANTS--Population samples of approximately 100 persons residing in both highly contaminated villages and control villages since the accident were compared. Individuals were selected on the basis of birth date as being 5, 10, 40, or 60 years old at the time of the study. All persons selected underwent a thyroid examination. INTERVENTIONS--None. MAIN OUTCOME MEASURES--Two main outcome measures were used, both for thyroid nodularity: clinical palpation and high-resolution ultrasonography. RESULTS--There was no significant difference in thyroid nodularity between the study groups. Nodules were palpated in 0.7% of children and 2.9% of adults. Discrete nodules were found by ultrasonography in 0.5% of children and 14.9% of adults. Multinodular goiter was found in 3% of adults. Nodules were more common in females. CONCLUSIONS--Four and a half years after the *Chernobyl* accident, the incidence, prevalence, and characteristics of thyroid nodules were the same in population samples from both highly contaminated and control settlements and similar to results reported for unexposed populations in other countries. TI In-situ determination of deposited radionuclide activities: improved method using derived depth distributions from the measured photon

spectra.

SO Health-Phys. 1992 Jun. 62(6). P 519-28.

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB When applying the standard method of in-situ gamma spectrometry to determine deposited radionuclide activities, an assumption is needed regarding the depth distribution of radionuclides in the ground. The method can be improved by assessing, from information contained in the spectrum, the attenuation of the radiation by the soil and vegetation. By comparing the count rates of the x ray and the gamma-ray lines of its daughter nuclide ^{137}mBa , the ^{137}Cs activity per area can be determined. The range of applicability of the method is discussed by means of an uncertainty analysis, and the method is applied to *post-Chernobyl* measurements. A comparison with the results of the standard method of in-situ spectrometry demonstrates the progress achieved by the proposed method. Nevertheless, the method still has some shortcomings for the peak analysis that could be improved by better detector resolution or better computer software. Author-abstract.

TI Area and time distribution of external and internal doses from *Chernobyl* fallout: the lack of correlation in Norway.

SO Health-Phys. 1992 Jun. 62(6). P 512-8.

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB Population doses from external radiation and internal food-based radioactivity were calculated each month for each municipality for 3 y immediately following the *Chernobyl* contamination in Norway. The main polluted regions are sparsely populated but comprise important food production areas. The external dose data base was calculated based on fallout deposition and measurements in dwellings, whereas the totally independent internal dose data base was calculated on a large number of food measurements and knowledge of both the food distribution system and the countermeasures taken. The internal dose in the densely populated municipalities was comparably higher than expected from local deposition, despite the fact that countermeasures had some effect. Thus, the correlation between internal and external dose for individual municipalities is rather weak. This study shows that a traditional deposition/transfer factor approach may be inappropriate if used in countries with large variation in population density and agricultural ecosystems and in combination with effective countermeasures. SO Radiat-Environ-Biophys. 1992. 31(2). P 133-9.

JT RADIATION AND ENVIRONMENTAL BIOPHYSICS.

PT JOURNAL-ARTICLE (ART).

AB A similar pattern of variation with time in observed maxima of daily dose equivalent rates in human thyroids (TD - microSv.d-1) and of daily fallout radioactivities (FR - kBq.m-2) has been found after the *Chernobyl* accident. An estimate of the time-lag between the maxima in TD lines and the preceding FR peaks was made of about seven days for adult and nine days for juveniles. Applying this time-lag it was possible to estimate transfer factors from the fallout to thyroid dose equivalent: the highest estimated values were 221 microSv/kBq.m-2 for adult and 641 microSv/kBq.m-2 for juvenile thyroids. These values differ from those published by UNSCEAR (United Nations 1988), which have been calculated for various regions of Czechoslovakia, from ingestion and inhalation intake estimates. A broad variation of transfer factor values could be expected to result from such transfer calculations using ingestion and inhalation estimates. The findings also support the concept of a need for prolonged iodine prophylaxy after emissions of radioiodine into the environment. Author-abstract.

TI Leukaemia incidence after iodine-131 exposure `see comments:.

SO Lancet. 1992 Jul 4. 340(8810). P 1-4.

JT LANCET.

PT JOURNAL-ARTICLE (ART).

AB Leukaemia is one of the most prominent late effects of exposure to ionising radiation. We have studied the incidence of leukaemia among 46,988 Swedish patients exposed to iodine-131 (¹³¹I) for diagnostic reasons or to treat hyperthyroidism or thyroid cancer. The observed number of leukaemias was compared with that expected based on incidence data from the general population. The mean absorbed dose to the bone marrow was estimated as 14 mGy (range 0.01-2.226). 195 leukaemias occurred more than 2 years after exposure, and the standardised incidence ratio (SIR) was 1.09 (95% confidence interval 0.94-1.25). Similar, but again not significantly, increased risks were seen for chronic lymphocytic leukaemia (CLL) (SIR = 1.08), a malignant condition not found to be increased after irradiation, and for non-CLL (SIR = 1.09). The risk of leukaemia did not vary by sex,

age, time, or radiation dose from ¹³¹I. One reason for the absence of a radiation effect, other than chance, includes the possible lowering of risk when exposure is protracted over time as occurs with ¹³¹I. Excess leukaemia risks of more than 25% could thus be excluded with high assurance in this population of mainly adults. These results should be reassuring to patients exposed to ¹³¹I in medical practice and to most individuals exposed to the fall-out from the *Chernobyl* accident. Author-abstract.

JT SCIENCE OF THE TOTAL ENVIRONMENT.

PT JOURNAL-ARTICLE (ART).

AB After the *Chernobyl* accident in April 1986, considerable deposition of radionuclides occurred regionally in eastern, central and northwestern Sweden. Locally, the fallout of radiocesium exceeded the remainder from atmospheric nuclear weapons tests by several magnitudes. Since the end of the 1960s samples of organs from various plant and animal species, annually collected at different localities, have been preserved in the Swedish Environmental Specimen Bank (ESB). In this work samples from the ESB have been used for retrospective studies of radioactive pollution. The activities of Cs-134 and Cs-137 in muscle tissues from reindeer, Rangifer tarandus, and pike, Esox lucius, preserved in the ESB, were measured. The samples were collected annually; the reindeer at three localities in northern Sweden and the pike at one of them. In material collected prior to the *Chernobyl* accident, the levels of Cs-137 were 57-180 Bq/kg in reindeer and 14-24 Bq/kg in pike, fresh weight basis. These levels relate to earlier nuclear bomb tests. A significant decrease was found in pike during the *pre-Chernobyl* period (1971-86). In *post-Chernobyl* samples the burden of Cs-137 varied from amounts equal to the former levels in the northernmost locality and up to 80 times higher for the maximum values in the southernmost locality. The highest value recorded was 18,425 Bq/kg in reindeer. The geographic variations in reindeer from *Chernobyl* fallout were in accordance with the pattern of deposition estimated by aircraft surveys performed in May 1986. The ratio between 'new' and 'old' radiocesium burdens in pike, caught in 1987, approached the corresponding ratio for reindeer grazing in the precipitation area of the lake; 33 and 19, respectively. AB The permissible level of a radionuclide mixture, resulted from the
Chernobyl burst, in the human being lungs was determined for two
kinds of compounds: absolutely insoluble compounds and soluble
compounds in the state of equilibrium. For this purpose the data
were used concerning the radionuclide composition and aerosol
disperse in lower atmosphere which were obtained by the Department
for Dosimetric Control (NPO "Pripiat"). The results of measurements
of ¹³⁷Cs content taken by the use of human radiation spectrometer
(HRS) needed an adequate estimation: low level of ¹³⁷Cs in the human
lungs and body within the *Chernobyl* NPP, zone does not guarantee
radiation security. The notion "permissible content" and the
possibility of using thereof in the individual dosimetric control are
discussed. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB After the *Chernobyl* nuclear accident, game meat and, in particular, sheep meat in the Republic of Croatia showed a high degree of radioactive contamination compared to large livestock. The activity concentrations of ¹³¹I, ¹³⁴Cs, and ¹³⁷Cs were measured in meat and internal organs (i.e., lung, liver, kidney, and heart) of game (e.g., venison, hare, and wild boar) and sheep that were used as biological indicators of radioactive contamination. In order to estimate the importance of game and sheep as a dietary source of radioactivity, the effective dose equivalent for the average and critical population (hunters and livestock raising families) were calculated. The data indicated that sheep meat represents greater risk for the human population, in case of a nuclear accident, than game meat. The share of meat from sheep (4.4%) prevailed over the share of meat from game (0.5%) when comparing the average intake of meat per inhabitant in Croatia. This result pointed to an increased risk for families who depend mostly on sheep meat in the case of a nuclear accident.

JT HEREDITAS.

PT JOURNAL-ARTICLE (ART).

AB Chromosome aberrations were analysed in 1222 peripheral blood lymphocytes from 24 reindeer, Rangifer tarandus L., calves from central Norway, where considerable fallout from *Chernobyl* accident had occurred, and in 1532 lymphocytes from 26 calves from three different districts in Northern Norway which were not affected by fallout from the accident. Three dicentrics, two rings, and three translocations were detected in calves from the exposed area, while no dicentrics, nor rings and only one translocation were detected in the control calves. The frequency of chromatid-type aberrations and chromosome deletions did not significantly differ between the two groups. Although the present study is based on a limited number of observations, the radioactive burden in the exposed reindeer, and the differing character of the chromosome aberrations in the two groups, might indicate that certain genetic effects have occurred as a result of the *Chernobyl* accident in Norwegian reindeer in the most contaminated areas. AB One of the aims of epidemiologic surveillance is to assess the role of environmental factors acting during pregnancy (teratogens) in abnormal development of the nervous system. The data of Eurocat, a european system of congenital anomaly surveillance, was analysed and evaluated. Great geographical variation is observed in the prevalence of neural tube defects. Geographical variation in the prevalence of microcephaly, hydrocephaly and holoprosencephaly, may

be related to problems of definition, validation and precision of diagnosis. A better definition of the unit of surveillance is required for anomalies where phenotypic heterogeneity is linked to aetiologic heterogeneity (such as neural tube defects) and for anomalies which range from minor to major forms (such as microcephaly). The strengths and deficiencies of the surveillance system for central nervous system anomalies are revealed by its performance in the evaluation of the *Chernobyl* accident.

PT JOURNAL-ARTICLE (ART).
AB OBJECTIVE--To obtain further information about the risks of childhood leukaemia after exposure to ionising radiation at low doses and low dose rates before or after birth or to the father's testes shortly before conception. DESIGN--Observational study of trends in incidence of childhood leukaemia in relation to estimated radiation

exposures due to fallout from atmospheric nuclear weapons testing during the 1950s and 1960s. SETTING--Nordic countries. SUBJECTS--Children aged under 15 years. MAIN OUTCOME MEASURES--Incidence rates of leukaemia by age at diagnosis, sex, country, and calendar year of diagnosis or year of birth; exposure category; relation between leukaemia and exposure for children aged 0-14 and 0-4 separately. RESULTS--During the high fallout period the average estimated dose equivalent to the fetal red bone marrow was around 140 mu Sv and the average annual testicular dose 140 mu Sv. There was little evidence of increased incidence of leukaemia among children born in these years. Doses to the red bone marrow of a child after birth were higher, and during the high exposure period children would have been subjected to an additional dose equivalent of around 1500 mu Sv, similar to doses received by children in several parts of central and eastern Europe owing to the *Chernobyl* accident and about 50% greater than the annual dose equivalent to the red bone marrow of a child from natural radiation. leukaemia incidence and red marrow dose was not related overall, but rates of leukaemia in the high exposure period were slightly higher than in the surrounding medium exposure period (relative risk for ages 0-14: 1.07, 95% confidence interval 1.00 to 1.14; for ages 0-4: 1.11, 1.00 to 1.24). CONCLUSIONS--Current predicted risks of childhood leukaemia after exposure to radiation are not greatly underestimated for low dose rate exposures. Author-abstract.

AB A total of 455 women, both pregnant and nonpregnant ones, permanently living in zones I and II of ionizing irradiation, were examined in 13 months after the *Chernobyl* Power Plant accident. Monocyte phagocytic activity and humoral immunity parameters were under study. An imbalance of the immunity parameters were characteristic of all the examinees living in zone I: they presented with disordered phagocytic activity of the monocytes, elevated levels of circulating R proteins, reduced production of natural and specific antibodies, changed concentrations of the principal immunoglobulin classes. The immune status of women living in the zone II was found lowered at the expense of reduced phagocytic activity of the monocytes, production of natural antibodies and immunoglobulins, shifted to either sides R protein levels, this necessitating immunocorrective therapy before pregnancy onset. PT JOURNAL-ARTICLE (ART).

AB In October 1990 a Netherlands humanitarian fact finding mission on aid to people affected by the *Chernobyl* disaster visited contaminated regions in Russia, Byelorussia and the Ukraine. The mission consisted of medical, socio-psychological and agricultural experts. The results of radioactivity measurements on food products sampled in the contaminated areas are reported here and the radiation burden for the Soviet citizens due to these products is discussed. The radiocaesium contamination measured in 19 food products ranged between 0 and 170 Bq kg⁻¹ and 40K from 25 to 200 Bq kg⁻¹ in the fresh product. Strontium-90, measured in a few samples, was found to be between 1.8 and 30 Bq kg⁻¹. Mushrooms and reindeer moss were very highly contaminated: from 103,000 to 284,000 Bq kg⁻¹ of radiocaesium in the fresh product. Strontium-90 in these samples was 7.8-1550 Bq kg⁻¹. The contamination of all food products was far below the stated limits, except for mushrooms. Extrapolation of the results to the total food consumption gave the radioactive burden due to this food as an estimated 0.2 mSv per year. All of the food products investigated, except mushrooms, can be regarded as safe with respect to radioactive contamination. In addition to sampling agricultural produce, field exposure measurements were also carried out. The measured values, expressed in equivalent doses, ranged from 1.8 to 14 mSv per year at a height of 1 m, with a median value of about 4 mSv per year. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB Increased atmospheric radioactivity after the accident in *Chernobyl* was first detected on air filters. Measurements were begun in Valencia on May 2, 1986, with the maximum activity being observed around May 3-4, 1986. As a consequence of this accident, annual campaigns of measurements on migrating birds (several species of aquatic birds and song-thrushes) were started. The data corresponding to the campaign immediately after the accident

(1986/87) show a generalized contamination (approximately 50% of the measured specimens). Significant levels of ¹³⁴Cs, ¹³⁷Cs and ¹¹⁰Agm were found. It is important to note that ¹¹⁰Agm is only present in *Aythya ferina*. In the successive campaigns in 1988/89 and 1989/91 few samples were found to be contaminated and only ¹³⁷Cs was identified. Strontium-90 was measured and identified in some specimens, mainly in their bones. Author-abstract.

JT ANALYST.

PT JOURNAL-ARTICLE (ART).

AB Depth profile measurements of ^{137}Cs and ^{134}Cs were carried out in 11 permanent pastures that had been exposed to fallout from the *Chernobyl* accident. In addition to gamma-ray spectrometric analysis, the selected pastures were characterized by several soil parameters, the influence of which on transfer was investigated. Sampling of soil and pasture grass was undertaken during a period extending from the Spring of 1987 to the Autumn of 1988. The results show that there has been limited downward migration of *Chernobyl-derived* caesium. In October 1988 more than 88% of the ^{137}Cs attributable to *Chernobyl* was mainly confined to the top 10 cm of undisturbed soil, with 79% on average in the top 5 cm. The distribution of *pre-Chernobyl* caesium at the 11 sites was also evaluated. In an investigation of the influence of soil parameters on transfer to grass, a negative correlation with pH was observed in 1987. In April 1987 concentration ratios for ^{137}Cs in grass ranged from 0.03 to 0.49. In general, comparison of the concentration ratio values showed a decreasing trend over the 18 months. TI Development of a laboratory method to predict rapidly the availability of radiocaesium.

SO Analyst. 1992 Mar. 117(3). P 505-9.

JT ANALYST.

PT JOURNAL-ARTICLE (ART).

AB A simple extraction procedure has been developed to assess rapidly the probable extent of the transfer of radiocaesium into ruminant food products soon after a nuclear accident. The in vitro extractions were validated against true absorption measurements of different forms of radiocaesium in the sheep gut. Extractions were performed on a range of different radiocaesium sources. Some of these sources were artificial (ionic radiocaesium adsorbed onto bentonite, silica spheres and filter-papers) and others were environmentally contaminated `silt from the Ravenglass Estuary contaminated by effluent from British Nuclear Fuels Limited (BNFL)

Sellafield, and upland grass and heather contaminated by *Chernobyl* fallout:. Laboratory experiments concentrated primarily on the use of simple inorganic extractants in competitive ion-exchange processes. Of the reagents used, 0.1 mol dm⁻³ stable caesium chloride solution was the most effective extractant. The proportion of radiocaesium extracted by 0.1 mol dm⁻³ caesium chloride correlated well with measurements of true absorption. Extracting radiocaesium using 0.1 mol dm⁻³ caesium chloride proved to be an inexpensive and rapid method of predicting the availability of radiocaesium for absorption in the ruminant gut, giving results within 24 h. Further extractions were carried out using cellulase/pepsin simulated digestions and ovine rumen fluid. Results suggested that the availability of radiocaesium from some inorganic sources may be underestimated using such techniques. Author-abstract.

TI Investigations of radiocaesium in the natural terrestrial environment in Norway following the *Chernobyl* accident.

SO Analyst. 1992 Mar. 117(3). P 501-3.

JT ANALYST.

PT JOURNAL-ARTICLE (ART).

AB Radioactive fallout from the *Chernobyl* accident affected parts of central Norway to a considerable extent, in particular the ¹³⁴Cs+¹³⁷Cs deposition had a significant impact on the natural environment. When this became apparent, a comprehensive radioecological research programme was initiated in order to study the behaviour of radiocaesium in boreal and alpine ecosystems, with emphasis on food-chains leading to exposure of species used for human consumption, i.e., reindeer and freshwater fish. In this paper results from the terrestrial part of this research programme during the period 1986-1990 are presented. The work was mainly confined to the mountain areas of Dovre and Rondane. Parallel studies were performed in eutrophic and strongly oligotrophic communities. The influence of local variations in topography and microclimate on the observed radiocaesium levels in topsoils, lichens and vascular plants was studied in detail. Currently a significant re-distribution of radiocaesium from the originally strongly exposed surfaces to those that were less exposed is observed. In the soil, radiocaesium is strongly retained in the litter and raw humus layers. Current levels in lichens are 1-2 orders of magnitude higher than in vascular plants. This strongly affects the seasonal variation of radiocaesium in reindeer, showing winter maxima of about 5 times higher than the August levels. The radiocaesium levels in reindeer showed a decline of approximately a factor of 3 during the period 1987-1990. Other animal species studied in the programme exhibited substantially lower radiocaesium levels than reindeer, but a considerable interspecies

variation was observed. Author-abstract.

TI Concept of seasonality in the light of the *Chernobyl* accident.

SO Analyst. 1992 Mar. 117(3). P 497-9.

JT ANALYST.

PT JOURNAL-ARTICLE (ART).

AB Seasonality could have a strong influence on the radiological impact of environmental radioactive contamination. Short-lived radionuclides (e.g., ¹³¹I) and those that mainly enter the food chain by direct contamination (e.g., ¹³⁷Cs) are especially important in this context. In particular, the contamination of cereals is influenced by seasonality. For temperate latitudes it is generally true that radioactive contamination during winter, when the fields lie fallow and the domestic animals are stabled, will result in a significantly lower radiological impact than if a similar contamination were to take place in the summer shortly before harvesting. The impact of the *Chernobyl* accident on the radioactive contamination of human diet was strongly influenced by seasonality. Author-abstract.

SO Analyst. 1992 Mar. 117(3). P 493-6.

JT ANALYST.

PT JOURNAL-ARTICLE (ART).

AB In order to compare the transfer factors of ¹³⁷Cs deposited after the fallout from the *Chernobyl* accident with ¹³⁷Cs from nuclear weapons testing, soil and vegetation samples have been collected from a semi-natural ecosystem in western Norway. For the ¹³⁷Cs from *Chernobyl*, 85% is found in the upper 5 cm of soil, whereas most of the nuclear weapons test ¹³⁷Cs is found between 3 and 12 cm in the soil profile. The transfer factors from soil to vegetation are calculated to be 0.41 +/- 0.07 m² kg⁻¹ for the nuclear weapons test ¹³⁷Cs and 0.40 +/- 0.22 m² kg⁻¹ for *Chernobyl* ¹³⁷Cs. Hence, the results show no significant difference between the two fallouts. The effective ecological half-life of ¹³⁷Cs for this ecosystem is estimated to be between 10 and 20 years. Wash-out and binding effects seem to be of minor importance for the uptake. Author-abstract.

JT ANALYST.

PT JOURNAL-ARTICLE (ART).

AB A sequential extraction procedure has been applied to study the speciation of *Chernobyl-derived* radionuclides (^{137}Cs and ^{90}Sr) in soils from Norway, and from Byelorussia and the *Chernobyl* region in the USSR. Most ^{137}Cs (greater than 80%) was strongly associated with soil components, whereas ^{90}Sr was more mobile, up to 70% being found in the easily extractable fractions. The ^{90}Sr : ^{137}Cs ratio decreased with the distance from the reactor, reflecting the higher proportion of hot particles deposited in the regions close to the reactor, and the easily extractable fraction of ^{90}Sr was significantly lower in the soils collected from the *Chernobyl* area. The distribution of stable Cs and stable Sr in the extraction fractions was similar for the various sites. Therefore, the location-specific differences in the distribution of ^{90}Sr and, to a lesser extent, ^{137}Cs arise because of fallout speciation rather than because of local environmental factors. TI Migration rates of radionuclides deposited after the *Chernobyl* accident in various North German soils.

SO Analyst. 1992 Mar. 117(3). P 475-9.

JT ANALYST.

PT JOURNAL-ARTICLE (ART).

AB In three soils typical for Northern Germany including Eutric Cambisol, Orthic Podsol and Eutric Histosol (Food and Agriculture Organization nomenclature), distributions of ^{90}Sr , ^{134}Cs , ^{137}Cs and $^{239}\text{Pu} + ^{240}\text{Pu}$ in the soil profiles were determined. Sampling was performed more than 3 years after deposition of *Chernobyl* fallout nuclides. Migration rates calculated with a compartmental model showed no significant differences between Cs originating from either atomic weapons or *Chernobyl* fallout. This result indicates that *Chernobyl* Cs may have reached sorption equilibrium with the soil matrix 3 years after the accident. Both the compartmental model and the dispersion equation reproduce distributions of most of the activities, but fail to reproduce some (minor) activity fractions that show increased mobility. JT ANALYST.

PT JOURNAL-ARTICLE (ART).

AB The vertical activity distributions of fallout ^{238}Pu , $^{239+240}\text{Pu}$, ^{241}Am , ^{134}Cs and ^{137}Cs in a forest soil (Hapludult) were determined at several locations in a spruce stand separately according to their origin (global fallout or *Chernobyl* fallout). To determine the rate of migration of these radionuclides in each soil horizon, the observed depth profiles of the radionuclides were evaluated with a compartment model. In the top organic horizons (LOf1 and Of2), the migration rates for all radionuclides from both sources were above 0.5 cm per year. In the Oh horizon the migration rates observed for global fallout Pu, Am and Cs were similar (0.2-0.4 cm per year). Compared with Pu, however, the mobility of Am is slightly, but statistically significantly, enhanced. The highest rate in this layer was found for *Chernobyl-derived* radiocaesium (2 cm per year). In the layers of the mineral horizon (depth 0-2, 2-5 and 5-10 cm) the observed migration rates were very similar for global fallout Pu (0.08-0.7 cm per year) and Am (0.1-2 cm per year). In comparison, the migration rate of global fallout radiocaesium was about half in each layer. The highest rate was observed again for *Chernobyl-derived* radiocaesium (0.5-3 cm per year).

SO Analyst. 1992 Mar. 117(3). P 465-8.

JT ANALYST.

PT JOURNAL-ARTICLE (ART).

AB Soil samples from nine field experiments on cultivated grassland showed a variation in deposition of radiocaesium, expressed as the relative standard deviation, from 11 to 111% within an area of $16.5 \times 10 \text{ m}^2$. At the site with the highest variability, situated in a mountainous region of south eastern Norway, a further study was performed. Double sampling including surface measurements with in situ gamma-spectrometry using a portable multi-channel analyser (3 x 3 in NaI detector) and limited soil sampling gave the same average deposition and standard error as an extensive soil sampling. There were no trends in the deposition within the experimental field and most of the variation was found within plots ($1.5 \times 2.5 \text{ m}^2$). 'Hot spots' were found in connection with small depressions (2-5 cm) in

the terrain, and the area of a hot spot was estimated to be 100 cm² from field measurements with a Geiger-Muller counter.

JT ANALYST.

PT JOURNAL-ARTICLE (ART).

AB This study investigated the relationship between altitude and ¹³⁷Cs fallout in soils and plants. The soils and plants, *Calluna vulgaris*, *Erica cinerea* and *Molinia caerulea*, were sampled across a transect of two valleys in north-western Ireland. The results provided evidence that greater ¹³⁷Cs deposition to soils occurred at higher altitudes, and the data supported the findings of a previous investigation in the same area. A valley effect, whereby greater concentrations of ¹³⁷Cs accumulated in plants on the lower altitudes of the valley floors, was shown to be significant. Deposition values for total ¹³⁷Cs in soils were not correlated with plant concentrations, although a relationship between concentrations in *C. vulgaris* and *M. caerulea* was found to be statistically significant. No relationship was observed between the ¹³⁷Cs from weapons fallout with that of *Chernobyl* origin in the 0-10 cm depth soils, although a significant correlation emerged between the same two components measured in *C. vulgaris*. The results suggest that existing definitions of concentration ratios and transfer factors are, for many reasons, inappropriate for studies of soil to plant transfer of ¹³⁷Cs in peatland ecosystems. PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).
AB Among nuclear analytical techniques, neutron activation analysis (NAA) is particularly useful for environmental studies. It affords low detection limits for many elements, high specificity and few sources of systematic error, which means that high accuracy is attainable. Neutron activation analysis is particularly useful for trace and ultra-trace analysis of environmental samples (water, soils, rocks and biological material). In trace element work associated with pollution, instrumental NAA is a powerful technique for multi-element surveys, in particular when combined with other spectroscopic techniques. Nuclear techniques, as with most analytical techniques, cannot be used to distinguish between different physico-chemical forms of an element per se. When used in combination with appropriate separation techniques, however, nuclear techniques can provide valuable information about trace element speciation in environmental and biological systems. From dynamic tracer experiments, i.e., addition of chemically well defined labelled compounds to environmental systems, valuable information can be obtained on the distribution of species and on microchemical processes influencing the physico-chemical forms. In these laboratories, speciation studies on trace elements in natural waters have been carried out by using instrumental NAA in combination with physical separation techniques, such as dialysis and ultrafiltration, in situ and in the laboratory. Dynamic radiotracer experiments have provided important information about processes influencing the speciation of trace elements in aquatic systems. Sequential

extraction techniques have proved to be useful in studies on sediments and soils when combined with NAA. Sequential extractions also provide significant information about the physico-chemical behaviour of radionuclides supplied to natural soils from the *Chernobyl* accident. Author-abstract. 39 Refs.

PT JOURNAL-ARTICLE (ART).

AB The outcome of pregnancies in the county of Sor-Trondelag, in Norway, during the 27 months preceding and 21 months after the *Chernobyl* accident has been analysed on the basis of time of conception. The analysis showed a significant decrease in the number of conceptions during the three months immediately after the accident (April-June 1986). This finding can be interpreted to mean fewer "planned" conceptions. The *Chernobyl* accident did not seem to have had any impact on the proportion of conceptions ending as spontaneous abortions or ectopic pregnancies. There was a significant drop in the proportion of pregnancies ending as induced abortions during the year after the accident compared with the year before. However, due to some variation during this year it is difficult to draw any definite conclusions concerning the impact of the accident on induced abortions in this county. The proportion of pregnancies ending as births increased significantly during the year after the *Chernobyl* accident compared with the year before. Author-abstract.

JT BRITISH DENTAL JOURNAL.

PT JOURNAL-ARTICLE (ART).

AB Radiation hazards in dental practice have long been recognized, and the dangers from ionising radiation during dental radiography are discussed elsewhere. Continuing legislation will undoubtedly help reduce the risk of over-exposure and accidents. Nevertheless, it is of some concern that radiation safety is still ignored by some: for example, one recent survey in the UK showed that not all radiography sets conformed to modern safety standards. However, the profession also has reason to be concerned about more public radiation hazards that may affect them, and their families and others, and may, without

denying the importance of dental radiation protection, have far greater effects on health. Well-known examples of domestic radon exposure occurred in the UK, particularly in the Lake District and the South West, and the nuclear reactor accidents--notably at *Chernobyl* in 1986. Author-abstract.

PT JOURNAL-ARTICLE (ART).
AB Cytogenetic effects of chronic irradiation in *Crepis tectorum* populations growing within 30 km of the *Chernobyl* atomic power station were determined by scoring the frequency of chromosome aberrations in first-mitosis-metaphases of root meristematic cells during seed germination. In the first year after the accident there were large differences in the distributions of radionuclides on the plots where the three studied populations were growing. Gamma-irradiation exposure rates were in the range 5-10 mR h⁻¹ (beta-irradiation exposure rates were about 10 times higher). The highest frequency of cells with chromosome aberrations was 9.1% in Population 1, in which cells with multiple aberrations were often observed. In the second year after the accident, six populations were studied growing in plots with exposure rates ranging from 0.02 to 20 mR h⁻¹. Chromosome aberrations were found in 1.4 and 2.2% of the cells at the two highest exposure rates. In a few cases, seedlings were observed where all cells of the root meristem had the same chromosome aberration; in 20 cases these aberrations were heterozygous and in one it was homozygous. The highest frequencies of such karyotypic alterations in the root were 6.2 and 6.6% at the two highest exposure rates. Reciprocal translocations, inversions and complex rearrangements with increased or decreased amounts of genetic material were registered among such changed karyotypes. The presence of plants with altered karyotypes may indicate the existence of active microevolutionary processes in chronically irradiated

populations. Author-abstract.

JT SCIENCE OF THE TOTAL ENVIRONMENT.

PT JOURNAL-ARTICLE (ART).

AB The *Chernobyl* accident heavily contaminated the largest aquatic system in the Ukraine, requiring the development of a model-based decision support system in the field of aquatic radioecology. The main objectives of the system were to simulate and predict radionuclide dispersion in the Pripyat-Dnieper River-reservoir system, assess the effectiveness of special hydraulic countermeasures designed to decrease the rate of radionuclide dispersion in the water bodies, and support the Dnieper reservoirs' management operations. A hierarchy of mathematical models was developed. A two-dimensional (2-D) vertical-longitudinal model, a 2-D lateral-longitudinal model, a one-dimensional (1-D) channel model and a box-type model are briefly presented. These models describe the main features of radionuclide dispersion, including the processes governing radionuclide-sediment interactions. Examples of the models' applications are presented to show the peculiarities of radionuclide dispersion in this aquatic system. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB Studies were carried out during July and September 1986, April 1987, and October 1988. Radioactive fallout after the *Chernobyl* atomic power station (APS) accident induced catastrophic effects on populations of small pine-litter faunae within the 3 km zone around the station. Effects on soil faunae were not so marked due to shielding by the soil, or on litter faunae at the edge of the 30 km zone due to distance from the source. Thirty-gray doses did not directly affect adult animals in the soil and litter, but impacted their eggs and juveniles. Resident populations recovered slowly during the first year after the accident. Insect migration into the contaminated area was the primary source of soil animal population recovery. After 2-2.5 years, marked differences between populations in the contaminated and control areas were no longer found.

PT JOURNAL-ARTICLE (ART).

AB One of the problems facing the program in the wake of the *Chernobyl* accident is the estimation of genetic damage to plants and animals. Special attention was directed to studying the influence of radioactive pollutants at the accident site by means of an appropriate test system, using standard genetic subjects. The present study describes such investigations. Levels of persistent genetic damage in natural populations of *Drosophila melanogaster* found in the vicinity of the *Chernobyl* accident site were examined from August 1986 to September 1989. Evidence is presented which indicates a relationship between the levels of radioactive pollution resulting from the *Chernobyl* accident and increasing genetic damage to exposed populations. The possible reasons for the decrease of mutation frequency observed in 1988 and 1989 are also discussed. Furthermore, evidence is presented which suggests that radiosensitive *Drosophila* mutants may be particularly sensitive indicators of radioactive pollution. Author-abstract.

AB As is proved by nuclear disaster in *Chernobyl* Nuclear Power Plant (NPP), iodine prophylaxis may be respected as one of the most urgent and effective methods of prevention of radiation injury of the thyroid gland in the population affected. Author has studied factors and methods of its efficacy and reliability. On the basis of experiments in rats, analytical ways of determination of the dietary iodine intake (iodine supply) of people living around NPP Paks (Hungary) as well as compartment modelling, experiments it is shown, that for optimisation of iodine prophylaxis in masses it is very important to increase the iodine supply up to the recommended values. Combined use of decreased doses of potassium iodide and perchlorate was found to be the optimal way for removal of radioiodine from pregnant organisms and their offsprings following accidental intake of radioiodine. PT JOURNAL-ARTICLE (ART).

AB On the basis of the data obtained from 61 cases of accidental exposure (0.1-12.5 Gy) at the *Chernobyl* A.P.S. the kinetics of acute radiation bone-marrow syndrome was analyzed and radiosensitivity of the entire spectrum of human granulocytic compartment cells was estimated. The radiosensitivity estimates were made by a "functional" criterion, developed by the authors, which was based on the comparative ability of irradiated and nonirradiated bone marrow cells of different maturity to produce peripheral blood neutrophils. Changes were found in physiology of myeloid cells during their maturation: the maturation mechanism, for cells of the committed pool, was "attached" to the division process, whereas these processes were independent for cells of the dividing and maturing pool. It is once again confirmed that the transit time of a maturing myeloid cell, to begin with the primarily committed one and to end with a peripheral blood neutrophil, is not constant and lasts normally for 32 days. PT JOURNAL-ARTICLE (ART).

AB A study was made of the morphological status of hepatocytes, the
antioxidant activity of lipids and composition of phospholipids, and
dehydrogenase activity in the liver of field mice taken from seven
regions of the *Chernobyl* A.P.S. zone with different levels of
contamination in 1987. There observed multiple types of destructive
damages to the organ; depletion of liver lipids by antioxidants;
diminution of phospholipids within the total lipid level;
considerable increase in the phosphatidyl choline/phosphatidyl
ethanolamine ratio and in the relative content of phospholipid
lysoforms; and inhibition of dehydration processes. In the absence
of a strict correlation between the changes in the biophysical and
biochemical parameters or between the severity of degenerative
changes in hepatocytes and the level of external irradiation, certain
relationship was followed up between liver lipid depletion by
antioxidants, inhibition of dehydration processes and the number of
wild rodents which developed dystrophic changes in the organ. These
structural and functional changes were found in the liver of wild
rodents taken from all the regions: this indicated a considerable
sensitivity of the parameters of the regulatory cell systems and
hepatocytes to the effect of technogenic contamination.

AB A clinical and immunological study is presented of 1030 practically healthy persons inhabiting Kiev from the moment of the *Chernobyl* accident. It was established clinically that during the last 5 years more frequent became acute respiratory viral infections, exacerbation of existing infection foci, appearance of complaints of reduced working capacity, somnolence apathy, increased fatiguability, worsening of memory, periodic subfebrility and oth. This symptom complex was determined as the "increased fatiguability syndrome". It was characterized immunologically by different changes showing most frequently a reduction of the functional activity of natural killers. The authors analyze different variants of immunological disorders in this group of subjects and give practical recommendations on using immunotropic drugs. They emphasize the importance of a service of clinical immunology in Ukraine able to organize special services to the population. Author-abstract.

TI `Peripheral blood of children exposed to radiation as a consequence of the *Chernobyl* AES accident:.

SO Pediatriia. 1991. (12). P 21-6.

PT JOURNAL-ARTICLE (ART).

AB As many as 103 children exposed to minor doses of radiation after the *Chernobyl* accident were examined for peripheral blood morphology. Statistical and individual analysis did not reveal any pathological alterations on the part of the hemograms of the radiated children. At the same time they manifested certain deviations in the form of leukopenia, lymphopenia and neutropenia, suggesting the action produced by radiation factor. On the whole, these alterations were characterized as adaptation ones of multifactorial genesis. The data obtained support an assumption that the changes in the quantitative composition of blood exposed to radiation in the doses not exceeding the maximal permissible limits were not remarkable, occurring within the physiological boundaries and could be detected only during observations made over time. Emphasis is laid on the necessity of further monitoring of the hemopoietic system of the radiated children according to the current principles of dispensary observation. Author-abstract.

TI `Assessment of the immunohematological status of children exposed to low doses of ionizing radiation in the early and late periods after the *Chernobyl* AES accident:.

SO Pediatriia. 1991. (12). P 16-20.

PT JOURNAL-ARTICLE (ART).

AB The qualitative and quantitative parameters of hemopoiesis and immunocompetent cells were studied in 365 children in the early "iodine" and long-term periods after the accident. In accordance with primary response, a group consisting of 28 subjects with so-called "radiation injury" was distinguished. The early period was marked by unusual qualitative and quantitative hematological changes which, however, did not lead to the development of the hematological syndrome characteristic of acute radiation injury. Certain deviations that corresponded to somatic pathology were detectable at the late periods after the accident. Author-abstract.

TI Whole-body cesium 137 activity up to 4 years after the *Chernobyl* reactor accident in premature newborns, newborns, infants, and children.

SO Pediatrics. 1992 Mar. 89(3). P 407-10.

JT PEDIATRICS.

PT JOURNAL-ARTICLE (ART).

AB Cesium 137 activity was measured after the *Chernobyl* incident in a whole-body radiation counter (4-pi-scintillation counter) in 85 premature and mature newborns (group 1), 174 infants and young children up to 2 11/12 years (group 2), and 48 children between 3 and 8 years (group 3) from Bonn (Germany) and surroundings. In 1987 the mean level of radioactivity in group 2, at 3.7 Bq/kg body weight corresponding to a mean radiation exposure of 11 muSv/y, was lower than that of group 1 (5.8 Bq/kg, 17 muSv/y) and 3 (9.4 Bq/kg, 28 muSv/y). Up to 1990 the values of all groups revealed a continuous decrease. The latest measurements showed mean values of 0.5 Bq/kg (1.5 muSv/y) in group 1, 0.6 Bq/kg (1.8 muSv/y) in group 2, and 0.8 Bq/kg (2.4 muSv/y) in group 3. A comparison with present cesium 137 values and determinations of the end of the 1950s and beginning of 1960s, both in adults, showed good agreement. The effective

dose-equivalent rates amounted to less than 1% of that from natural radiation exposure. These levels should present no teratogenic risks to the population studied and, while there are theoretical mutagenic risks, the dose is so low that no increase in measurable mutagenic effects should be observed. TI The importance of soil adhered to vegetation as a source of radionuclides ingested by grazing animals.
SO Sci-Total-Environ. 1991 Sep. 107. P 237-54.
JT SCIENCE OF THE TOTAL ENVIRONMENT.
PT JOURNAL-ARTICLE (ART).
AB Soil ingestion has been identified as a potentially important source of radionuclides to grazing animals. Seasonal patterns of soil adherence to vegetation and its implications for the radionuclide intake of grazing animals were measured at two west Cumbrian sites. Soil adhesion to vegetation was highly seasonal, being highest in autumn and winter. At Site 1 (a lowland pasture close to the British Nuclear Fuels plc Sellafield Reprocessing Plant, Cumbria, UK), vegetation samples were found to consist of up to 46% soil (by dry weight). Therefore, the importance of soil as a potential source of

radionuclides to grazing animals was also seasonal; soil comprised up to 92% of the ¹³⁷Cs and potentially all of the ^{239/240}Pu of vegetation samples at Site 1 and up to 62% of the ¹³⁷Cs at Site 2 (an upland farm contaminated following the *Chernobyl* accident). Analyses of sheep faecal samples confirmed the seasonal importance of soil as a potential source of radionuclides. The importance of soil adhering to vegetation, as a source of contaminant ¹³⁷Cs, increased with time after the *Chernobyl* accident. Calculations of soil ingestion must be made when the intake of radionuclides by grazing animals is being studied. In some circumstances, present radioecological models may considerably underestimate the importance of soil ingestion.

SO Health-Phys. 1992 Mar. 62(3). P 245-9.

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB The fallout from the explosion and fire at the *Chernobyl* nuclear power plant concentrated levels of up to 10 kBq ¹³⁷Cs kg⁻¹ dry weight in the fuel peat harvested during the summer of 1986 in Finland. We investigated the behavior of fallout radionuclides ¹³⁷Cs, ¹³⁴Cs, ¹⁰⁶Ru, ¹⁴⁴Ce, ¹²⁵Sb, ⁹⁵Zr, and ^{110m}Ag together with naturally occurring ²¹⁰Pb and ²²⁶Ra in the combustion of this contaminated peat in four different power plants. The elements antimony, ruthenium, lead, and cesium were enriched on the smallest particles, indicating that they were in a volatile chemical form, while cerium, zirconium, and radium were nonvolatile at the combustion temperatures. This result confirms the previous finding that ruthenium is volatile in

combustion. Although metallic ruthenium requires 2,310 degrees C to melt, some of its oxides melt and evaporate at much lower temperatures. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB Biological dose indication using chromosomal aberrations analysis is a reliable method of diagnosing acute radiation disease and prognosing bone marrow syndrome severity. Cytogenetic methods permit one not only to estimate the mean radiation dose in the subjects exposed that is most important in case of relatively uniform irradiation, but also to reveal the non-uniformity of radiation exposure. Estimation of aberrant cells in bone marrow puncture biopsy specimens obtained from different sites of the hemopoietic tissue and analysis of chromosomal aberrations in peripheral blood lymphocyte cultures can be used for this purpose. Materials including those obtained at the *Chernobyl* accident were analyzed with the use of the above methods, their advantages and shortcomings are considered, and equations of dose-response curves are presented. AB Fallout of Nickel-63 (T_{1/2} = 100 a) produced in small amounts at nuclear weapon tests following the neutron activation of weapon

construction material was investigated by studying carpets of lichen collected during 1961 to 1988 at the Lake Rogen district in central Sweden (62.3 degrees N, 12.4 degrees E). The maximal level of ^{63}Ni in the lichen carpet, which occurred in 1964, was about 0.6 Bq kg⁻¹, dry weight, and decreased to 0.1 Bq kg⁻¹ in 1988. The deposition pattern for ^{63}Ni was similar to other fallout radionuclides such as ^{137}Cs , ^{90}Sr and $^{239} + ^{240}\text{Pu}$. The concentrations of stable Ni were relatively constant at 0.5 to 1.0 microgram g⁻¹ throughout the years resulting in, for example, a specific activity (^{63}Ni /stable Ni) of 0.5 Bq mg⁻¹ in 1964 and 0.1 Bq mg⁻¹ in 1988. The total area content of ^{63}Ni was estimated to be 1.0 Bq m⁻² and the activity ratio $^{63}\text{Ni}/^{60}\text{Co}$ was estimated to be 0.03 in 1966. The *Chernobyl* accident in April 1986 did not significantly increase the levels of ^{63}Ni . For the measurement of these extremely low-levels of ^{63}Ni , 200 g of dry material (about 1 kg fresh) were ashed and leached with aqua regia after hydroxides had been precipitated with ammonia, leaving Ni in the aqueous phase. Nickel was extracted as a dimethylglyoxime complex by chloroform and back-extracted with HCl. Finally, Ni was electroplated onto copper discs from an ammonium sulfate medium at high pH. The radiochemical yield was determined by atomic absorption spectrometry of stable Ni before and after electrodeposition.(ABSTRACT TRUNCATED AT 250 WORDS).

PT JOURNAL-ARTICLE (ART).

AB Within the framework of the International *Chernobyl* Project, the IAEA's Seibersdorf Laboratories organized an intercalibration exercise among some of the laboratories which were involved in assessing the environmental contamination in the USSR due to the accident. The objective was to assess the reliability of the radioanalytical data for food and environmental samples, which were used to assess the doses. In the initial study reference materials from the stocks of the IAEA's Analytical Quality Control Services (AQCS) were re-labelled and submitted to 71 laboratories as blind samples. These natural matrix materials included samples of milk (containing 2 different levels of radioactivity), soil, air filters and clover. The concentrations of radionuclides in these samples were known from previous intercalibration exercises. The overall range in performance was broad, which is similar to what has been observed in previous international intercomparisons. The results

obtained by gamma-ray spectrometry tended to be somewhat underestimated, on average. On the other hand, the laboratories showed an overall tendency to overestimate ^{90}Sr and possibly ^{239}Pu , which were analysed radiochemically. The intercalibration exercise is continuing with nine materials, including: soil, grass, hay and milk powder contaminated with fallout from the *Chernobyl* accident. These materials, which were prepared by laboratories in the USSR, are now being tested by AQCS prior to future intercomparison exercises. Work with these materials is expected to continue for several years.

PT JOURNAL-ARTICLE (ART).

AB Numerous European cancer registries are working together to evaluate the current trends in the incidence of childhood leukemias after the *Chernobyl* accident. The study is coordinated by the International Agency for Research on Cancer. The primary objective is to establish whether the accident has resulted in an increase in the number of cases. The results will also allow an evaluation of the clusters which could be reported. According to the provisional estimations, the accident could lead to an increase of an average of 0.8% of the frequency of new cases in the European regions covered by the study. For the whole of Switzerland, this increase would correspond to 0.5 supplementary cases per year. Author-abstract.

Report of a meeting and consequences for Switzerland (editorial):.

SO Soz-Praventivmed. 1991. 36(4-5). P 209-16.

JT SOZIAL- UND PRAVENTIVMEDIZIN.

PT EDITORIAL (EDI). MEETING-REPORT (MET).

AB Today's society is concerned about the dangers of ionising radiation, especially in the aftermath of *Chernobyl.* On the other hand, there exists a widespread lack of understanding radiation biology and radioepidemiology--the very sciences which provide the data from which today's risk estimates have been derived. The papers in this issue of the Journal were presented at a workshop on "Low level radiation and cancer: data and methods" held on 10th-11th December in Feuisberg, near Zurich. The meeting was organised by the Institute of Social and Preventive Medicine of the University of Zurich under the auspices of the Swiss Federal Office of Public Health. Its aims were threefold. First, to give an introduction to some basic facts and methodological issues in radiation physics, biology and epidemiology. Secondly, to give an overview of the availability of data for radioepidemiological research in Switzerland and, thirdly, to evaluate possible research strategies in this country. A list of some notions and units commonly used in the radiation sciences serves as an introduction to the field (G. Schuler et al.). In using units and notions it is important to distinguish the description of biological experiments and epidemiological observations from definitions and risk projections proposed by international reports and consensus bodies for radioprotection purposes. The next papers deal more specifically with selected aspects of the basic sciences. Dosimetry means quantifying the physical effects of ionizing radiation in human tissue; this is not a straight-forward procedure (I. Cordt). The foundations of general radiation biology are succinctly summarised by C. Michel. An account of our present knowledge and theories of radiation carcinogenesis is provided by W. Burkart. W Lutz compares dose-response models of chemical carcinogenesis with those used in radiation carcinogenesis. During the last decade the epidemiological foundations of radioprotection have changed considerably. Longer follow-up studies have become available from the atomic bomb survivors and from other cohorts. A new dosimetry system (DS 86) has been introduced for Hiroshima and Nagasaki. Exposure to domestic radon has become a major focus of interest. Not only the data, but also the methods of analysis and modeling of risks have evolved, as shown by the recent reports of national and international scientific committees.(ABSTRACT TRUNCATED AT 250 WORDS). JT RADIOBIOLOGIIA.

PT JOURNAL-ARTICLE (ART).

AB The immune status of mice has been assessed by the whole complex of
data. The permanent action of low-level radiation has been shown to
suppress considerably the rate of reactions of the delayed-type
hypersensitivity and "graft versus host" disease, as well as NK and
specific cytolytic T-lymphocyte activity. The dynamics of
accumulation and the levels of antiviral antibodies in the serum,
lung and trachea extracts are virtually invariable. The resistance
of experimental animals to influenza is lower than that of
non-irradiated mice of the same line and age. The data obtained
indicate that the immune disturbances revealed are connected not only
with the alteration of lymphoid cell populations, but also with the
alteration of the immune regulation mechanisms. Author-abstract.

TI Transfer of radiocesium to ruminants in natural and semi-natural ecosystems and appropriate countermeasures.

SO Health-Phys. 1991 Dec. 61(6). P 715-25.

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).

AB A review of studies conducted before and after the *Chernobyl* accident is presented, showing that both the duration and the extent of radiocesium contamination of ruminants will be more severe in unimproved ecosystems compared with agricultural areas. Although such unimproved ecosystems provide comparatively small quantities of food for human consumption, the integrated dose from these areas to the human population can be large. Ecological characteristics that make unimproved ecosystems particularly vulnerable to this form of pollution include the presence of (1) soils that do not immobilize radiocesium and therefore allow its uptake into vegetation; (2) vegetation species with high uptake rates of radiocesium; (3) the predominant utilization by small ruminants which attain higher muscle radiocesium levels than cattle. Unimproved ecosystems, which often are located at high altitudes, are predisposed to receiving higher fallout because of high precipitation rates which enhance the likelihood of deposition. Countermeasures have been developed and used successfully to reduce radiocesium levels in ruminants grazing in unimproved ecosystems. Apart from decontamination by altering farming practices and providing uncontaminated feeds, sustained reductions of 50% to 80% in the radiocesium concentrations of both milk and meat have been achieved in many ruminant species when AFCF is given via a sodium chloride lick or as a sustained-release bolus. Food production in unimproved ecosystems must be evaluated separately from that of ordinary agricultural systems. In addition to detailed studies on the behavior of radiocesium, consideration should be given to the collection of aggregated transfer coefficients from various

ecosystems which were affected by *Chernobyl* fallout. By combining bioavailability estimates and aggregated transfer coefficients, based on *Chernobyl* and nuclear weapons test fallout data, it may in the future be possible to make a rapid assessment of both the immediate and the long-term impact of a future nuclear accident on food production in unimproved ecosystems. AB In a child born of a full-term pregnancy, unilateral diplophthalmos without proboscis was observed along with other craniocervical abnormalities (ipsilateral temporoparietal porencephaly, supernumerary teeth, and cervical cyst). A globe almost normal in shape and size was observed within the left orbit. The upper quadrant of this globe was attached to a smaller, pear-shaped, supernumerary eye containing a small lens, normal vitreous humor, ciliary body structures, avascular retina, choroid, and a rudimentary optic disk. When a two-peaked and enlarging intraocular mass was observed clinically, the eye was enucleated because of suspected neoplasm. The enlarging prominence had been caused by the growing second globe. Our findings indicated that a single primary optic vesicle was formed (globe I with an optic fasciculus), and some unknown damage was caused when this single primary optic vesicle induced the lens formation by contacting the ectoderm. Although the conception and early embryonal life of this child had taken place during a period of increased radiation exposure caused by the explosion of the nuclear plant at *Chernobyl,* U.S.S.R., in the spring of 1986, it seemed unlikely that the abnormality could have been caused by radioactive fallout in the mountains of Austria. PT JOURNAL-ARTICLE (ART).

AB The author bases and describes the computing laboratory and clinical system for screening groups at a higher risk for malignant neoplasms whose incidence is likely to increase due to irradiation. Two years after the disaster the detected group at a higher risk was 2-2.4 times larger than the control group among persons who received the total irradiation dose 5 rem and over as well as among persons who are to be removed from the area polluted with radionuclides whatever the dose. As the time elapsed since the disaster increases, the number of subjects with a higher level of biomarkers also grows. It is advisable that this system be introduced in all fields of the practical health care in the polluted and control areas to carry out goal-oriented treatment and diagnostic measures in the selected population groups. Author-abstract.

AB A total of 18 patients with acute leukemia from those exposed to radiation when they had liquidated the consequences of the accident at the *Chernobyl* Atomic Power Station were examined. Sixteen of them had acute myeloblast cell leukemia, one had acute lymphatic leukemia, and another one had acute promyelocytic leukemia. A complex of hematological, immunocytological, and cytochemical findings, as well as leukocytic and erythrocytic genetically determined antigen typing were used for diagnosis. Signs of severe vegetovascular dystonia was found to be followed by acute leukemia in all the patients. A relationship was established between the therapy resistance and the HLA antigen homozygosity in combination with genetically-determined low reactivity. There were no significant differences between the parameters in question and those in patients with acute leukemia who had been studied in the preaccident period. Author-abstract.

SO Soc-Sci-Med. 1991. 33(4). P 429-34.

JT SOCIAL SCIENCE AND MEDICINE.

PT JOURNAL-ARTICLE (ART).

AB Previous studies have concluded that radioactive fallout from *Chernobyl* may have caused an increase in perinatal mortality in West Germany and the U.S.A. The existence of marked geographical variations in contamination from *Chernobyl* in England and Wales provides an opportunity to investigate this question further by means of a geographical study. The highest doses from *Chernobyl* in England and Wales were in the counties of Cumbria, Clwyd and Gwynedd where there was heavy rainfall during the passage of the radioactive cloud. However, perinatal mortality in these areas did not rise relative to the national average in the year following *Chernobyl.* This negative finding was confirmed by a wider study of 14 counties grouped in accordance with levels of radioactive contamination of local milk. It is concluded that this study provides no evidence that radiation from *Chernobyl* caused a rise in perinatal mortality in England and Wales. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB A study was made of the effect of high radioactive contamination on the animal organism (C57BL/6 mice) and HeLa cell culture within the ten-kilometer zone of the *Chernobyl* A.P.S. accident. The total radiation dose, as calculated by a gamma-component, was 0.09 to 2 Gy. A long-term exposure of mice within the zone (cumulative dose of 1.8 to 2 Gy) caused a significant decrease in bone marrow stem potencies and changes in the brain vascular system; subsequent acute exposure of animals increased interferon titres in the serum to a much greater extent than a single acute exposure did. As to HeLa cells, irradiation there of with doses of 0.09 to 0.4 Gy during 15-20 postirradiation generations caused a decrease in the proliferative activity, an emergence of cells with micronuclei and of giant cells, and remote cell death. PT JOURNAL-ARTICLE (ART).

AB The genetic consequences of radioactive fall-out deposition from the *Chernobyl* (USSR) accident in Hungary was evaluated as a part of the ongoing programme on the population-based Hungarian Surveillance of Germinal Mutations. The surveillance is based on three groups of indicator conditions: 15 sentinel anomalies (indicators of germinal dominant gene mutations), Down's syndrome (an indicator of germinal numerical and structural chromosomal mutations) and unidentified multiple congenital abnormalities (indicators of germinal dominant gene and chromosomal mutations). Cases with these indicator conditions were selected from the material of the Hungarian Congenital Abnormality Registry. After the diagnostic accuracies were checked, familial and sporadic cases were separated. Only the latter group was evaluated for evidence of new mutations. The analysis did not reveal any measurable germinal mutagenic effects of the *Chernobyl* accident. Furthermore, there were no significant differences in the rates of these three groups of indicator conditions between regions with higher and lower increased background radiation. Author-abstract.

TI `Dosage of irradiation of the population in the Bryansk region with plutonium deposited in the soil after the *Chernobyl* AES accident:.

SO Med-Radiol (Mosk). 1991. 36(9). P 4-6.

PT JOURNAL-ARTICLE (ART).

AB Proceeding from the data on ^{238}Pu , ^{239}Pu , ^{240}Pu concentrations in the soil in different areas of the Bryansk Region, exposed to radioactive contamination after the *Chernobyl* accident, radiation dose exposures of residents as well as agricultural workers were assessed. Criteria of the ecological and radiation-hygienic standardization were used for calculation of values of dose factors, binding the alimentary and inhalation components of an irradiation dose with characteristics of Pu deposition in the soil. Inhalation of soil particles accounted for approximately 90% of a total radiation dose of the "soil" Pu component, and the alimentary component-for approximately 10% (of this, 99% were attributed to plant products). The authors proposed prognostic assessment of an expected effective equivalent dose for a period of 70 years for people, residing in these areas (0.08-0.45 cSi for the population and 0.6-3.2 cSi for mechanics). PT JOURNAL-ARTICLE (ART).

AB Since early 1986, a monitoring program for radionuclides in imported foods has been carried out by the Iraqi Atomic Energy Commission. After the *Chernobyl* nuclear reactor accident in the Soviet Union, the program was expanded; our laboratory was officially designated by the Iraqi Government to measure radionuclide activity concentrations in foodstuff imported from countries known to be severely contaminated by *Chernobyl* radioactive fallout. Gamma-spectrometric analysis was used. Food items such as powdered milk, lamb meat, poultry, cereals and grains imported into Iraq before the *Chernobyl* accident did not contain any detectable fission products. However, all lamb meat, 81% of the lentil, 44% of the powdered milk and chick-pea, and 17% of the roast beef samples were contaminated with 137Cs or 134Cs and 137Cs. The highest 137Cs contamination levels found were 82, 147, 420, 6 and 4 Bq kg-1, respectively. Contamination by 134Cs was approximately 50% of the values given above. Author-abstract.

SO Sci-Total-Environ. 1991 Jun. 105. P 1-12.

JT SCIENCE OF THE TOTAL ENVIRONMENT.

PT JOURNAL-ARTICLE (ART).

AB Intake, excretion and retention of gamma-emitting radionuclides were assessed in male rabbits fed a radioactive pelleted diet (¹³⁷Cs = 858 Bq kg⁻¹ as fed) containing 40% dehydrated alfalfa meal contaminated by *Chernobyl* fallout. In order to evaluate radionuclide retention, an experiment was carried out on 33 animals as follows: nine rabbits were slaughtered at the beginning of the trial, six were fed a radioactive diet for 42 days, six a radioactive diet for 21 days, six a radioactive diet for 21 days and a normal diet (¹³⁷Cs = 112 Bq kg⁻¹ as fed) for the following 21 days and six a normal diet for 42 days. All the animals were housed in individual metabolism cages throughout the trial. All faeces and urine were collected and analyzed separately and live weight and feed intake were measured on a weekly basis. At the end of the trial all the animals were slaughtered and the activities of net body and muscles were determined. Cesium-137, ¹³⁴Cs, ¹⁰³Ru, ¹⁰⁶Ru, ¹²⁵Sb, ^{110m}Ag and ⁴⁰K were measured by gamma spectroscopy. More than 85% of ingested cesium was excreted through faeces and urine (fecal much greater than urinary) and the retained ¹³⁷Cs in the carcass of the more contaminated animals was only 3% of the total ingested. The concentration of total cesium in muscle reached a maximum value of 156 Bq kg⁻¹, much lower than the EEC

guideline (600 Bq kg⁻¹), and the biological half-life for ¹³⁷Cs was calculated to be 11 days. The feed-body accumulation factors were determined in net body and muscle. Author-abstract.

PT JOURNAL-ARTICLE (ART).
AB A study of Down's syndrome in Lothian for the years 1978-1989
revealed a significantly higher than expected incidence of cases in
1987. The increased incidence was particularly significant among
women aged 35 years or more. The increase could not be attributed to
demographic changes on birth rates or to the age distribution of the
women concerned. A temporal association between the cluster of cases
and the events at *Chernobyl* in April 1986 was demonstrated. However,
according to current understanding, there is no biologically
plausible explanation to link the 2 events, given the reported levels
of radioactive fallout in the Lothian region, resulting from the
Chernobyl disaster. An explanation for the increased incidence of
Down's syndrome in 1987 remains outstanding. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB For Berlin (West) the rate of trisomy 21 among newborn and all prenatally diagnosed cases can be almost completely recorded, including the maternal age distribution. During the 9-year-period from 1980 and 1988 the average number of trisomy 21 per month was about 2, following a Poisson distribution. A significant increase (P less than 0.01) was observed in January 1987, exactly 9 months after the *Chernobyl* accident. In a supraregional study based on greater than 30,000 prenatal diagnoses performed in 1986, no significant effect could be observed. However, the highest rates of trisomy 21 were observed in the more heavily contaminated, southern part of Germany. The majority of these fetuses were conceived during the period of greatest radioactive exposure. The data are discussed with respect to the effect of low-dose radiation around the time of conception on the induction of non-disjunction in man.

AB The annual and monthly distributions of congenital abnormalities and pregnancy outcomes as confounding factors were evaluated in Hungary in reflection of the accident at the *Chernobyl* reactor. The different congenital abnormality entities and the components of fetal radiation syndrome did not show a higher rate after the *Chernobyl* accident in the data-set of the Hungarian Congenital Abnormality Registry. Among confounding factors, the rate of induced abortions did not increase after the *Chernobyl* accident in Hungary. In the 9th month after the peak of public concern (May and June, 1986) the rate of livebirths decreased. Three indicator conditions: 15 sentinel anomalies as indicators of germinal dominant gene mutations, Down syndrome as an indicator of germinal numerical and structural chromosomal mutations, and unidentified multiple congenital abnormalities as indicators of germinal dominant gene and chromosomal mutations were selected from the material of the Hungarian Congenital Abnormality Registry. Diagnoses were checked, familial and sporadic cases were separated and only the sporadic cases were evaluated. The analysis of indicator conditions did not reveal any measurable germinal mutagenic effect of the *Chernobyl* accident in Hungary.

 PT JOURNAL-ARTICLE (ART).
 AB Four regression models have been fitted to data of the monthly number of induced abortions in Italy between January 1984 and April 1986, in order to predict the number which would have occurred in the 5 months following the *Chernobyl* explosion. In model I the average number of abortions per day in each month was the dependent variable and calendar months, a linear time trend and previous month's value were the independent variables. Model II included a quadratic time trend term in addition to the independent variables used in model I. Models III and IV were like models I and II except that the dependent variable was the average number of abortions per working day in each month and the effect of the previous month's value was omitted. The 4 models all implied that an excess number of abortions were performed in the 5 months following the *Chernobyl* accident. The mean daily excess was estimated to be 28 and 52 per day for models I and II and the mean excess per working day was estimated to be 20 and 30 by models III and IV, respectively. Clearly the estimated magnitude of the excess depends on whether the quadratic time trend is included among the explanatory variables, but these results imply that the excess is unlikely to be merely due to chance.  AB Pregnancy outcome has been studied in terms of legal abortions, early spontaneous abortions and total number of pregnancies (in an ad hoc study covering 6 counties) as well as various perinatal health problems (on the basis of routinely recorded data for epidemiological surveillance from the Medical Birth Registry of Norway). Apparently, no effects were observed in terms of an increased occurrence of legal abortions, while spontaneous abortions increased from 7.2% of all pregnancies during the last 12 months before the accident to 8.3% after the accident `corrected:.. At the same time, the total number of pregnancies somewhat decreased. Based on monthly measurements in each municipality of external and internal (food-based) doses, dose-response associations were assessed for a number of perinatal health problems. No associations were observed. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB During the months following the accident in *Chernobyl,* Denmark experienced an increasing rate of induced abortion, especially in regions with the largest measured increase in radiation. As the increase in radiation in Denmark was so low that almost no increased risk of birth defects was expected, the public debate and anxiety among the pregnant women and their husbands "caused" more fetal deaths in Denmark than the accident. This underlines the importance of public debate, the role of the mass media and of the way in which National Health authorities participate in this debate. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB The number of legal abortions in Sweden increased around the time of the *Chernobyl* accident, particularly in the summer and autumn of 1986. Although there was no recording of reasons for legal abortions, one might have suspected this increase to be a result of fear and anxiety after the accident. However, seen over a longer time perspective, the increase in the number of abortions started before and continued far beyond the time of the accident. There was also a simultaneous and pronounced increase in the number of births during the years subsequent to the accident. Therefore, it seems unlikely that fear of the consequences of radioactive fall-out after the *Chernobyl* accident resulted in any substantial increase of the number of legal abortions in Sweden. PT JOURNAL-ARTICLE (ART).

AB On April 26, 1986 a major nuclear disaster took place at 1 h 24 min local time, destroying the fourth reactor of the *Chernobyl* plant. Five years later the consequences of the disaster are still not fully known. Nevertheless the long term future of nuclear energy in the world is uncertain. Questions need to be answered by observing hard facts if emotional attitudes are not to prevail over reality. The reactor and its core were destroyed by an explosion, causing two radioactive jet emissions of iodine 131, followed by caesium 137. Both elements are mainly incorporated in the body via food. The *Chernobyl* disaster was a consequence of inadequate safety regulations and human error. Enforcement of strict regulations are likely to be highly effective in preventing a further catastrophe. However, governments should consider another possibility. What would be the consequences for public health if a terroristic act deliberately destroyed a nuclear power station? Author-abstract.

AB Technological or man-made disasters are a growth industry. Widely publicized industrial disasters like those in Bhopal and *Chernobyl* are only the tip of the iceberg of human and environmental risk from technological development. Other less well publicized disasters, including the contamination of food, water and air, have affected millions of people. The 'slow' technological disasters - like air pollution, pesticides, radiation, lead, asbestos and other industrial hazards - also compromise human intellectual, behavioural and physical development. Although it can be argued that there are hazards attached to virtually every industrial activity and that it is almost impossible to remove completely the risk of technological disasters, it is possible to reduce this risk by decentralizing or deconcentrating knowledge on technological processes. Global recommendations may provide a framework for priority action, but they are obviously not applicable everywhere with the same intensity. A measurement-based approach is described that is beginning to have an effect in several developing countries. Author-abstract. 93 Refs.

SO Med-Radiol (Mosk). 1991. 36(7). P 50-2.

PT JOURNAL-ARTICLE (ART).

AB In order to reveal possible genetic effects of the *Chernobyl* accident for human populations, a cytogenetic survey of 33 agricultural workers from 2 areas of the Kaluga Region with different radiation backgrounds (villages of Mladensk and Ogor) was conducted in 1989. At the time of investigation a dose of ^{137}Ce for Mladensk was 3.7 ci/km², that for Ogor--1.17 ci/km². Lymphocyte cultivation was performed after the standard semimicromethod for 50 hours; about 155-300 cells were analyzed for chromosome aberrations of each individual, the total number of metaphase plates in 2 groups being 9360. One-factor dispersion analysis has shown that the rate of exchanges of a chromosome type, specific for radiation, was higher in the workers of the village of Mladensk than in the workers of Ogor (p less than 0.05). Thus statistically significant differences in the rate of metabolic aberrations of a chromosome type were revealed in the two study groups with different radiation backgrounds. A high sensitivity of cytogenetic analysis for population biological indication of irradiation was shown. Author-abstract.

SO Health-Phys. 1991 Sep. 61(3). P 401-4.

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB After the *Chernobyl* accident, a number of radiation protection criteria for the early and intermediate phases of the accident were set up by the authorities to protect the public in affected areas. For the late phase, an intervention level of 350 mSv over a lifetime, the so-called 350-mSv concept, has been recommended by the National Council on Radiation Protection and Measurements (NCRP) in the USSR. This concept has been strongly criticized by opponents in the affected republics as being far too high and therefore inhumane. However, a lifetime dose of 350 mSv would impose on an individual an average annual risk of the order of $10(-4) \text{ y}^{-1}$, which is lower than the annual individual risk due to nonradiation causes prevailing in many areas in the USSR. The basic radiation protection principles for nuclear accidents as recommended by the International Commission on Radiological Protection (ICRP) and the International Atomic Energy Agency (IAEA) are at present very difficult to apply in the USSR because the concepts of risk and acceptable risk are rejected categorically. If, however, principles of justification and optimization had been used, the result might have shown that the present lifetime dose limit of 350 mSv, as an intervention level, is actually too low. PT HISTORICAL-ARTICLE (HRT). JOURNAL-ARTICLE (ART).

AB Cancer may be induced by chemicals, ionizing radiation and certain viruses. The first causal relationships between occupation and increase in cancer have been reported two and half centuries ago. In the meantime, many other occupational toxicants have been identified as cancer inducing agents. However, quantitative risk estimates can be established in a few cases only. On the other hand, modern epidemiological investigations have brought about the main causes of cancer in highly civilized populations as certain life-styles; approximately 35% are attributed to inadequate diet and nutrition, 30% to tobacco, 7% are hormone-related in context with human reproduction, 4% due to occupational exposures, 3% may be caused by alcohol consumption, 1,5% by UV radiation and 1% by medicines (cytostatics included). Cancer risks from radiation exposure are comparatively very low. Although radiation can be measured precisely and reliably as physical units, cancers induced by nuclear weapon fallout and precipitation from the accident of *Chernobyl* will never be detected by epidemiological methods due to their minimal

proportions. The attribution of causes obtained in this way allows for the conclusion: human cancers are mostly due to chemically definable factors, and thus are avoidable. Author-abstract.

SO Horm-Metab-Res. 1991 May. 23(5). P 236-8.

JT HORMONE AND METABOLIC RESEARCH.

PT JOURNAL-ARTICLE (ART).

AB The aim of the present study was the observation of the frequency of antithyroid autoantibodies in the population in low endemic goitre area after mass iodine prophylaxis after the *Chernobyl* catastrophe and the estimation of TSH and thyroid hormones secretion in this population. On the basis of the investigations carried out we could conclude that the frequency of antithyroid autoantibodies in the population with confirmed endemic goitre is comparable to the frequency of antithyroid autoantibodies in the healthy population. ATA occurrence in children after iodine prophylaxis could confirm the hypothesis that thyroglobulin immunity is higher after iodine intake. The lower T3 concentration observed in the group with antithyroid autoantibodies suggests that autoantibodies may be involved in the thyroid hormones synthesis or peripheral conversion of thyroid hormones. AB Following the *Chernobyl* accident, Austria was one of the most
contaminated Western European countries. Predictions of internal
dose in humans due to this contamination were based on the average
activities in major dietary products and average consumption rates.
We have measured the amount of radiocesium in human adult muscle
samples obtained at forensic autopsies within a limited area in
Southern Austria over a period of 4 yr. From the measurements, we
have estimated a mean individual effective dose equivalent of 252.2
muSv (25.2 mrem) due to internal exposure to radiocesium during this
4-yr period. This estimate, based on actual measurements, is
approximately 25% of the predicted dose and is less than 50% of the
dose received in the body from naturally occurring potassium-40.
Comparisons of radiocesium activities measured in muscle tissues with
data obtained after nuclear weapons tests and whole-body countings
are given. Author-abstract.

before and after the *Chernobyl* accident.
SO Radiat-Environ-Biophys. 1991. 30(2). P 147-57.
JT RADIATION AND ENVIRONMENTAL BIOPHYSICS.
PT JOURNAL-ARTICLE (ART).
AB The Cs-134/137 activities were measured from different tree organs of
spruce, larch and sycamore maple. Two locations in South Bavaria
were monitored during a period of 2.5 years following the *Chernobyl*
accident. Samples taken in 1985 allow to determine the Cs-137
contamination before the accident. Increasing Cs-137 activities from
older to younger needle years of Picea abies caused by root-uptake of
the global weapons' fallout are due to the high phloem mobility of
this element and the remaining of the needles at the tree for about
6-7 years. In contrast, the Cs-137 activity was much smaller in
leaves of larch and sycamore maple. After the *Chernobyl* accident,
the higher contamination of spruce greater than larch greater than
sycamore maple is dependent on the roughness of bark, absolute bark
surface and the existence of leaves during the deposition of
Chernobyl-derived radioactivity. The Cs-134/137 activity (Bq/kg
d.w.) was about 25-times higher in bark compared to wood of Picea
abies and 1.5-4.7 times higher in directly contaminated twig-axes
than in leaves. Till the end of the investigation the major
contamination of the shoots was due to direct deposition of cesium on
the trees. A maximum of 5-15% of the total activity of the directly
contaminated branches of the plants was calculated to be part of
root-uptake, depending on the amount of initial retention. 20% of
the translocated cesium into new leaves of larch and about 50% into

sycamore maple resulted from root-uptake 2.5 years after the accident. Author-abstract.

AB OBJECTIVES--To compare caesium-137 concentrations in patients from the Western Isles Health Board, Glasgow area, and other parts of the

Scottish mainland, and to investigate the source of ^{137}Cs in patients from the Western Isles. DESIGN--Study of hypertensive patients having electrolyte concentrations measured, including ^{137}Cs . Interview by questionnaire of island subjects about intake of foods likely to contain radiocaesium and the source of these foods. Measurement of ^{137}Cs and ^{134}Cs in food, urine, and vegetation. SETTING--Scottish mainland and Western Isles, 1979-86. All measurements before *Chernobyl* nuclear accident. PATIENTS--413 consecutive patients referred to the blood pressure unit for investigation of hypertension. 60 from the Western Isles, including 44 from North Uist; 32 from North Uist participated in the dietary analysis. MAIN OUTCOME MEASURES--Concentration of radiocaesium in the body, urine, food, and vegetation. Islanders' consumption of local produce. RESULTS--Patients from the Western Isles had five times higher body concentrations of ^{137}Cs (median 2.54 (interquartile range 1.25-3.73)) Bq/gK) than did patients from around Glasgow (0.47 (0.26-0.66) Bq/gK) and other parts of the Scottish mainland (0.42 (0.24-0.71) Bq/gK). Islanders often consumed local milk and mutton, but ate local fish rarely. ^{137}Cs and ^{134}Cs were present in coastal (21.6 Bq/kg ^{137}Cs , 0.25 Bq/kg ^{134}Cs) and moorland (135.9, 0.65 Bq/kg) grasses and in islanders' urine (2.01, 0.013 Bq/l). Lower concentrations (0.336, 0.004 Bq/l), were found in the urine of Glasgow controls (p less than 0.001 for both isotopes). CONCLUSIONS--Islanders have excess body ^{137}Cs concentrations, most of which probably comes from local milk and lamb. The radioactivity is not above the recommended safety limit. The presence of ^{134}Cs suggests that nuclear reprocessing is the source of some of the radiocaesium. Author-abstract.

PT JOURNAL-ARTICLE (ART).
AB Natural (tritium, ^{14}C , ^{40}K , ^{226}Ra) and man-made radionuclides (^{90}Sr ,
 ^{134}Cs , ^{137}Cs) were determined in soil (top 30 cm), vine leaves,
grapes and wine in eight locations of the most important viticultural
regions in the Federal Republic of Germany. The results obtained in
1983-1985 have been published previously. Part II of this study
presents results obtained in 1986 and 1987, i.e. after the reactor
accident at *Chernobyl* in the Soviet Union. The mean content of ^{137}Cs
before (after) *Chernobyl* was 4 (9) Bq/kg dry matter in soil, 0.07 (3)
Bq/kg fresh matter in leaves, 0.02 (0.4) Bq/kg in grapes, and 0.008
(0.9) Bq/L in wine. As compared with 1986, distinctly lower levels
were found in leaves, grapes and wine in 1987. In 1986 the content
of ^{134}Cs was about half that of ^{137}Cs . Owing to its shorter
half-life, ^{134}Cs was below the detection limit in many of the 1987
samples. Transfer factors such as from soil to leaves and from soil
to grapes for caesium agreed well in 1983-1985 and 1987, but showed
considerable deviations in 1986, due to the ubiquitous contamination
of the environment. Results of ^{90}Sr determinations confirmed other
reports showing this radionuclide to be a very minor contributor to
the total radioactivity released at *Chernobyl.* No effect of the
reactor accident on levels of the other radionuclides was detected.

PT JOURNAL-ARTICLE (ART).

AB On April 26, 1986, after partial fusion and confining loss by explosion of a nuclear reactor, 5×10^7 Ci of radionuclides escaped from *Chernobyl.* Three years later, maps show contamination by radioactive isotopes (formed during that period) of 21,000 km² of Soviet soil, mainly in Byelorussia and part of the Ukraine. Decontamination measures have not been effective to date and 135,000 persons are being followed medically, taking into account the radioactive doses they received. An initial excess of morbidity from solid tumors has been noted much sooner than in the case of Hiroshima and Nagasaki, but its significance is in dispute. Three years later, only the extent of the ecologic disaster caused by the radioactive contamination can be confirmed. It is too early to draw conclusions about radiation-induced carcinogenesis for the contaminated population. Author-abstract.

SO Acta-Biol-Hung. 1990. 41(1-3). P 215-22.

JT ACTA BIOLOGICA HUNGARICA.

PT JOURNAL-ARTICLE (ART).

AB The radioactive fallout of the *Chernobyl* accident caused an increase in radiation dose of 20 to 110 per cent over the normal environmental burden to the inhabitants of Salzburg City in Austria (in a distance of about 1300 km from the accident). The structural chromosome aberration in the lymphocytes of the peripheral blood of 15 test-persons have been investigated one year after the accident. From two of these we know also the aberration frequencies before the accident which were significantly lower. The results from all test persons were pooled according to their Cs137 and Cs134 content, measured by whole body counter. Their mean additional blood doses from the incorporated caesium plus the external fallout radiation were 0.23, 0.36 and 0.55 mGy/yr. The aberration frequencies increased with dose. The slope of the best straight-line through the points was 2.0 ± 0.7 total chromosome type aberrations in 100 metaphases per mGy/yr. This result fits in well with former investigations of persons with individually calculated radiation burden from the environment. The sharp increase with dose at this low level is not compatible with values extrapolated from high doses. The usual dose assessment based on chromosome aberrations extrapolated from high to low doses is therefore not possible in the range considered in this investigation. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB The behavior of neutron-irradiated, simulated *Chernobyl* UO₂ particles containing ¹⁴¹Ce, ¹⁴⁴Ce, ⁹⁵Zr, ⁹⁵Nb, and ¹⁰³Ru in the gastrointestinal tract was investigated to obtain basic information for dosimetric and risk analyses of nuclear accidents. After the UO₂ particles were administered to rats intragastrically, the

distribution and retention of specific radionuclides were studied by using whole-body autoradiography and gamma-spectrometric analysis of tissues. None of the radionuclides were detected in liver, kidney, muscle, bone, brain, blood, and urine. Approximately 98% of the total administered radioactivity was excreted in feces within 3 days. A two times greater intestinal retention (about 6%) of ⁹⁵Nb than for the other radionuclides was observed 1 day after administration. The results indicate that this kind of relatively insoluble particulate material is not absorbed or retained significantly in the epithelial cells of the intestinal wall. Fallout particles containing high-energy beta sources, ¹⁰⁶Ru and ¹⁴⁴Ce, result in a very high radiation dose (up to several Gy/day) in the vicinity of a hot particle. Niobium-95 with low average beta energy (0.043 MeV (100%)) does not increase the total dose to the GI tract significantly despite its longer retention in the intestine. Evaluation of the biological effects of these particles in the GI tract by using a dosimetric model based on uniform distribution of activity may be misleading. Author-abstract.

SO Med-Radiol (Mosk). 1991. 36(5). P 21-3.

PT JOURNAL-ARTICLE (ART).

AB Karyometric analysis of blood lymphocytes of persons, exposed to low levels of radiation (up to 25 rem) during elimination of the consequences of the *Chernobyl* accident, has shown changes of lymphocyte densitometric-geometric parameters, characteristic for radiation exposure, observed in 188 of 294 examinees. The meaning of

these statistically significant changes is the following: percentage of the level of large lymphocytes is on the decrease whereas that of average and small ones is on the decrease. There is also a parallel rise of values of the area and perimeter of a lymphocyte nuclear section. The above shifts were observed against a background of normal indices of the absolute number and a relative content of blood lymphocytes. Karyometric analysis of lymphocytes indicated signs of radiation exposure 1-33 mos. after irradiation at small doses. Cytogenetic verification of diagnosis has shown sensitivity of the karyometric method of biological demonstration `correction of bioindication:, which can be recommended as an additional diagnostic test in chronic exposure to low levels of radiation for retrospective assessment. TI Radiocesium bioavailability: transfer of *Chernobyl* and tracer
radiocesium to goat milk.
SO Health-Phys. 1991 May. 60(5). P 665-73.
JT HEALTH PHYSICS.
PT JOURNAL-ARTICLE (ART).
AB The bioavailability of *Chernobyl-derived* radiocesium in hay, fungal
fruit bodies, willow bark, and soil was compared to tracer
radiocesium ($^{134}\text{CsCl}$) by measuring transfer coefficients (F_m) to goat
milk. The average F_m value from $^{134}\text{CsCl}$ of 11.9×10^{-2} d L⁻¹ was
taken to represent the maximal transfer to milk on the provided diet.
In 1986, the F_m value from hay was 35% of that from $^{134}\text{CsCl}$, thus
demonstrating the low bioavailability of recently deposited
radiocesium. Values in 1987 were also lower, with a mean of 76% of
that from tracer Cs. During 1988 and 1989, maximal F_m values were
observed, suggesting increased bioavailability from the year of
fallout to the following years. Transfer of radiocesium from two
fungal species harvested in 1988 and 1989 were 78% and 87%,
respectively, of that from tracer Cs, while bark was lower (62%).
Transfer from organic soil was only 7% of tracer radiocesium, and
therefore contribution from soil ingestion could only have a small
impact on the content of radiocesium in animals. Live monitoring
measurements and the excretion of ^{134}Cs in milk, urine, and feces
during a 50-d period was adequately described by a two-exponential
equation. Author-abstract.

AB The paper is concerned with the results of therapy of 115 patients with acute radiation syndrome after the *Chernobyl* accident. The chief methods of the effective therapy of bone marrow syndrome are antimicrobial drugs and fresh donor platelet mass transfusions. Hemopoietic stem cell transplantation (allogenic bone marrow or embryonic hepatocytes) is indicated and effective in a very limited number of patients in accident irradiation. Severe beta-burns of the skin remain an unsolved problem as a result of their spreading. Organizational principles of therapy of a great number of patients with acute radiation syndrome in a specialized hospital were described. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB A duplicate diet study has been carried out on a group of Harwell employees in order to investigate the food types in which radiocaesium from *Chernobyl* was most likely to be found, and also the intake of radiocaesium in food with relation to observed whole-body levels. The duplicate diet study indicated that the highest levels of radiocaesium were in milk and meat or fruit and vegetables.

Radiocaesium concentrations in food of all types are small compared to the most restrictive generalized derived limit. Daily intakes of radiocaesium measured by the diet study, of the order of 2-3 Bq day⁻¹, generally agreed with values calculated from whole-body measurements. Committed doses from radiocaesium have been estimated from dietary intakes to be in the range 3-29 μ Sv year⁻¹, while whole-body measurements indicate a range of 6-18 μ Sv year⁻¹; these doses are small compared to other sources of internal irradiation and to recommended limits. AB Concentration of ¹³⁷Cs, ¹³⁴Cs and potassium were measured in several
higher fungi and in substrates, soils, woods and litters in some
Kanto and the Koshin districts, Japan, following the *Chernobyl*
accident during October to November 1989. ¹³⁷Cs concentrations in
fungi were in the range of 0.7-101 Bq kg⁻¹.fresh. Maximum ¹³⁷Cs
level in them was observed in *Boletopsis leucomelas* (Pers.: Fr.)
Fayod. Significnatly higher levels of concentration ratios of ¹³⁷Cs
in fungi to substrates (e.g.; ¹³⁷Cs concentration.fresh in
fungus/¹³⁷Cs concentration.dry in soil), 10⁽⁻¹⁾ to 10 x 10⁽⁻¹⁾, were
found nearly 10 to 1000 times as much as leaf vegetables, root crops
and potatoes to substrates. It was confirmed that levels of
concentration ratios of potassium were similar to those of ¹³⁷Cs. In
all fungi, ¹³⁴Cs which released from the *Chernobyl* accident and is
not present in nuclear weapons fallout was not detected.

PT JOURNAL-ARTICLE (ART).

AB Radionuclide contamination of whole diets as a result of the *Chernobyl* accident has been measured following the collection of individual diets from adults and children during 1 week in June 1986. The study was conducted in three different parts of the UK, to represent rural areas of both high and low deposition of *Chernobyl* fallout, and an urban area where the food supply was likely to be derived from a more diverse range of sources. The overall caesium-137 plus caesium-134 concentrations in the diets was less than 5 Bq kg-1 fresh weight, and ranged from less than 0.8 Bq kg-1 to 22 Bq kg-1, the highest levels being found in diets from the high deposition area. The isotopic ratios confirmed contamination to have been predominantly of *Chernobyl* origin. These levels of radiocaesium would have given rise to an average committed effective dose equivalent to age 70 of less than 0.4 microSv, with a range of less than 0.05 microSv to 1.9 microSv, from intakes in the study week. The opportunity was also taken to analyse the samples for weapons fallout contamination, that is, strontium-89/strontium-90 and plutonium-239/plutonium-240. No diet contained strontium above the reporting level of 0.2 Bq kg-1 but 18% of the diets contained plutonium above the limits of detection (0.1 mBq kg-1), the highest of these being 12 mBq kg-1, found in a diet from one of the low deposition areas. PT JOURNAL-ARTICLE (ART).

AB The authors evaluate the radiation risk of children under 15 years whom they examined in 1984-1988 at the department of nuclear medicine in Jihlava by "in vivo" methods and compare the values with the radiation risk from the natural background and the *Chernobyl* disaster. The authors found that the radiation risk from a single renographic examination is by two orders lower than the radiation

risk from the natural background in the course of a whole year, which is approximately double the risk ensuing from the *Chernobyl* disaster. The radiation risk of a single scintigraphic examination is insignificantly higher than the risk from the natural background in one year. Although the ratio of renographic examinations in the group accounts for 92%, it accounts only for 11% of the total radiation load of the group. Conversely scintigraphic examinations account for 88% of the total radiation load but only for 7.9% in the group. The total radiation load of the investigated group in one year due to administration of radiopharmaceutical preparations is lower than its contemporary total load from a the natural background and the *Chernobyl* disaster. PT JOURNAL-ARTICLE (ART).

AB An investigation has been carried out to determine whether chromosome aberrations in peripheral blood lymphocytes reflect the elevated environmental dose of low-LET ionising radiation, mainly due to radiocesium from *Chernobyl* fallout, to the population living in Salzburg city. Sixteen volunteers were sampled 1 year after the *Chernobyl* accident. Two of these persons were also sampled before the accident, and then in 1988 and 1990. The radioactive environment of Salzburg city and the radiation burden of its inhabitants have been frequently determined before and after the accident. The Cs-137 content of the volunteers was measured by whole-body counting. The additional external plus internal radiation doses in the year 1987 to the tested individuals ranged between 15 and 68% of the former normal environmental burden. The aberration frequencies showed a sharp increase of about a factor 6 from the *pre-Chernobyl* dose rate (0.9. mGy/year) to the *post-Chernobyl* dose rate (about 2 mGy/year total) but then decreased again with higher additional dose. In the two persons analysed before and up to 4 years after the accident the aberration yield showed a significant increase from 1984/85 to 1987,

a decrease in 1988 and a further decrease in 1990. If these last 2 values are plotted against additional dose they fit the curve of the pooled 1987 values. The dose-effect curves revealed the same tendency as we found in various previous investigations and support the assumption that repair enzymes could be triggered by a certain amount of damage to the DNA. AB Iodine-131 concentrations were measured throughout the summer of 1986 in thyroids of lambs slaughtered at Ioannina (Northwestern Greece) following the accident at the *Chernobyl* nuclear reactor. During the survey, 40 thyroids were collected. The highest level of 131I detected was 2471 +/- 339 Bq per thyroid. The thyroids of 20 lambs did not contain detectable 131I concentrations, while the contamination content of the others was greatly variable. The transport of 131I from pasture to thyroids of lambs has been described through a simple model for the retention of 131I in the glands. The transfer coefficient f_T , expressing the steady-state equilibrium, was estimated to be 564 +/- 270 kg⁻¹ d. This result reflects the sensitivity of animal thyroids as biological radioiodine monitors. Author-abstract.

AB The epidemiology of Down syndrome (DS) was studied in the area which is covered by our registry of congenital malformations. For each of the 139 new DS cases which were ascertained during the period 1979 to 1987 more than 50 factors were studied and compared to those from control infants. The prevalence of DS was 1.17%; 3.6% of the DS cases were stillbirths and 14.4% were induced abortions. Karyotypes were obtained in 137 cases of which all but 7 were 47, + 21, 4 were mosaics (2.8%), and 5 had translocations (3.6%). Interchromosomal effect was a question in 3 cases. The most common types of associated malformations were cardiac anomalies (44.6%) and intestinal atresia. We did not observe seasonality or time/space clusters in spite of the *Chernobyl* nuclear accident. No paternal age effect was demonstrated. In our material the first-born infants were at lower risk of DS than the later born. Five percent of the mothers of DS had 2 previous spontaneous abortions (controls 2.8%). At birth, the DS infants measured less and their head circumference was lower than in control infants. Weight of placenta was also lower than in control infants. In our material there were 7.9% of consanguineous marriages ($P = .010$). The pregnancies of the DS children were often complicated by threatened abortions; 6.4% of the mothers of the DS children were diabetic ($P = .069$). For all other factors studied no statistically significant difference with respect to controls could be demonstrated. Author-abstract.

AB The analysis of the epidemiologic situation was made in view of tuberculosis in those areas of the Byelorussian SSR which suffered from radiation as a consequence of the accident at the *Chernobyl* atomic power plant. A higher level of tuberculosis morbidity among the population (especially among children and adolescents) is recorded in the areas of strict radiation control. The pattern of clinical forms of pulmonary tuberculosis tends to deteriorate in addition to a higher percentage of disseminated smear-positive lung processes. Besides, new difficulties arise due to the organization of an early detection of tuberculosis cases on account of limited X-ray screening of the population to decrease the radiation load on the body. Lower immune status of those subjected to the radiation is demonstrated. The authors predict an unfavorable development of the situation for the nearest future regarding tuberculosis incidence over the radionuclide-polluted territories of the Republic.

JT PROBLEMY TUBERKULEZA.

PT JOURNAL-ARTICLE (ART).

AB The levels of tuberculosis morbidity in the areas of a strict radiation control imposed as a consequence of the accident at the *Chernobyl* atomic power station are determined by the following two factors: outflow of young people (including children) whose tuberculosis morbidity is rather low; and lesser coverage of the population by preventive fluorographic examinations. In the majority of the areas of a strict radiation control, lesser coverage of the population by preventive fluorographic examinations has a predominant influence on the tuberculosis morbidity rates which appear to be lower than in 1985. At the same time the percentage of the destructive forms in newly diagnosed patients with respiratory tuberculosis happens to increase, while the proportion of those developing focal pulmonary tuberculosis appears to decrease. Tuberculosis case-finding is the urgent problem which should be achieved by means of non-radiation methods of detecting this disease.

PT JOURNAL-ARTICLE (ART).

AB The *Chernobyl* Nuclear Power Plant accident, in the Ukrainian Soviet Socialist Republic (SSR), on April 26, 1986, was the first major nuclear power plant accident that resulted in a large-scale fire and subsequent explosions, immediate and delayed deaths of plant operators and emergency service workers, and the radioactive contamination of a significant land area. The release of radioactive material, over a 10-day period, resulted in millions of Soviets, and other Europeans, being exposed to measurable levels of radioactive fallout. Because of the effects of wind and rain, the radioactive nuclide fallout distribution patterns are not well defined, though they appear to be focused in three contiguous Soviet Republics: the Ukrainian SSR, the Byelorussian SSR, and the Russian Soviet Federated Socialist Republic. Further, because of the many radioactive nuclides (krypton, xenon, cesium, iodine, strontium, plutonium) released by the prolonged fires at *Chernobyl,* the long-term medical, psychological, social, and economic effects will require careful and prolonged study. Specifically, studies on the medical (leukemia, cancers, thyroid disease) and psychological (reactive depressions, post-traumatic stress disorders, family disorganization) consequences of continued low dose radiation exposure in the affected villages and towns need to be conducted so that a coherent, comprehensive, community-oriented plan may evolve that will not cause those already affected any additional harm and confusion. SO Med-Radiol (Mosk). 1991. 36(2). P 33-41.

PT JOURNAL-ARTICLE (ART).

AB The paper is concerned with the results of measurements of characteristics of the air media in the zone of the damaged reactor as with the assessment of doses from internal irradiation on the basis of calculations of air media parameters and the results of actual measurements of the uptake and content of radionuclides in the personnel of the *Chernobyl* Nuclear Power Station and persons sent on mission there in 1986-1987, the results being obtained by indirect and direct biophysical methods of control of internal irradiation. The calculated data are well in accord with the results of actual measurements of the contents of radionuclides in the body. Internal irradiation of all tissues and organs, determined by the inhalation of a mixture of radionuclides, worked almost completely within the first year following the accident, the thyroid being the critical organ. In the next years internal irradiation for the personnel of the *Chernobyl* Nuclear Power Station was determined entirely by transuranic elements and was about 0.1 M.P.D annually for bone tissue. The value of a mean effective equivalent dose from internal irradiation in 50 years is 85 mSv for professionals, and a contribution of internal irradiation to the whole-body one over the first well as is 13%. PT JOURNAL-ARTICLE (ART).

AB The authors investigated prognostic significance of irradiation intensity with relation to the severity of a course of the bone marrow syndrome in the affected population at the *Chernobyl* accident. Absorbed doses were determined by analysis of lymphocyte chromosome aberrations and the time course of the blood neutrophil count. The evaluation of the severity of blood disorders by cytogenetic and hematological tests was shown to coincide in 85% of patients. Due to lack of information on irradiation physical data, an absorbed dose mean rate was assessed for the entire period of stay in the high radiation zone. In 81 patients mean dose rate values varied within 0.1-22 Gy/h. Further analysis has shown that a mean dose rate value in this range did not influence the prognosis of a course of the bone marrow syndrome in the affected persons (by the results of cytogenetic investigation of lymphocyte cultures). TI *Chernobyl* fallout in southern and central Finland.

SO Health-Phys. 1991 Mar. 60(3). P 427-34.

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB To study the levels and distributions of radionuclides released in the *Chernobyl* accident, we sampled surface peat from 62 sites in Southern and Central Finland and measured ¹³¹I, ¹³⁴Cs, ¹³⁷Cs, ¹³²Te, ¹⁴⁰Ba, ¹⁰³Ru, ⁹⁰Sr, ¹⁴¹Ce, and ⁹⁵Zr. The distribution of fallout activities was highly uneven, depending on movement of the

contaminated air mass and rainfall distribution during the critical days. The highest values observed were 420 kBq m⁻² of ¹³¹I and 70 kBq m⁻² of ¹³⁷Cs. The nuclide ratios showed wide and partly unexpected variations. The high-boiling-point, or nonvolatile, elements Ce and Zr were spread mostly on a 200-km-wide zone extending across Finland from southwest to northeast. The more volatile elements, I, Ce, and Te, showed quite a different, more widespread, fallout distribution, while an intermediate behavior was observed for Ba, Ru, and possibly Sr. These results can be explained by assuming that pulverized nuclear fuel material released in the reactor explosion on 26 April reached Finland via Poland and the Baltic Sea and traversed the country along the above-mentioned narrow zone, while volatile material, evaporated in the reactor fire from 26 April to 5 May, arrived in several waves and was consequently more widely and evenly spread. From their elemental melting and boiling points, Ru and Mo would appear to belong to the nonvolatile group and Sr to the volatile. Yet, their actual behaviors were opposite; Ru in particular was found in the nonvolatile as well as the volatile fallout, possibly because Ru activities were present in the fuel partly in the metallic state and partly as volatile oxides.

PT JOURNAL-ARTICLE (ART).

AB In persons who had accumulated radiocesium from the fallout of the *Chernobyl* nuclear reactor accident, the amount of radiocesium and radiopotassium was measured in the total body and in urine. The stable Cs content in the urine was determined at the same time by instrumental nuclear activation analysis. From the data obtained, the total body Cs pool was calculated to be 1500 micrograms, that of K 110 g. The Cs turnover rate was found to be 0.64%/d for men and 0.81 for women; the K turnover 2.4 and 2.7, respectively. The Cs:K ratio in the total body was 4 times higher than that in urine, demonstrating that, in relation to the intake, the body is able to accumulate more Cs than K. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB The National Commission on Radiation Defense (NCRD) of the USSR Health Ministry proposed standard values--maximum limit of life dose for the population equalling 35 ber per 70 years. Despite the seeming accordance of this value to NCRD recommendations according to which the equivalent dose of irradiation of a limited part of the population should not exceed 0.5 ber yearly, the NCRD does not take into consideration the irregular character of radiation. Numerous data from the literature are presented on the presence of some nonstochastic and stochastic effects even in such comparatively low doses showing the impossibility of acceptance of such standard values. AB Mice (CBAXC57BL) F of both sexes were exposed within the 10 km zone of *Chernobyl* nuclear power station. Genetic damage of phone chronic effect of increased radiation in exposed adult mice and in the course of embryogenesis was studied. The total absorbed radiation doses in testes varied from 1.85 to 0.42 Gy in embryos and from 3.4 to 2.7 Gy in adult males. Increase of dominant lethal mutations (DLM) and abnormal sperm heads (ASH) was only observed right after the end of exposure of adult males. The yield of reciprocal translocations (RT) in these males was relatively low. Among the males exposed at the stage of early embryogenesis, 4 heterozygotes for RT were revealed.

In other males of this group the RT yield was low. Author-abstract.

SO Health-Phys. 1991 Feb. 60(2). P 203-8.

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB From 3 May to 4 August 1986, thyroids of 416 postmortem subjects in Bratislava (population: approximately 400,000) were measured for 131I. Subsequently, dose rates in this organ for the day of exitus were calculated. Mean dose commitments were estimated by integrating linear or quadratic-periodic regression lines drawn through scatterplots of logarithmically transformed daily dose rates. The mean dose-commitment estimates in thyroids of adults were 0.74 and 0.58 mGy for linear and quadratic-periodic regression, respectively. The same for thyroids obtained from donors of fetal to 18 y of age were 1.67 and 1.77 mGy for liner and quadratic-periodic regression, respectively. A comparison of the actual thyroid radiation burden with its theoretical values calculated in the first days of contamination of the environment showed that the models used were safe enough to protect the population. Estimates of absolute risk for thyroid cancer showed that excess incidence that could be expected as a result of the *Chernobyl* accident shall remain obscured by the "spontaneous" incidence of this disease at geographic localization. PT JOURNAL-ARTICLE (ART).
AB An investigation was carried out in Sweden aimed at studying the possible genetic effects of the *Chernobyl* fallout on wild small mammals. The bank voles (*Clethrionomys glareolus* Schreb.) were obtained from three differently contaminated areas in Sweden and, for control, in an area with negligible contamination by fallout. Radionuclide determinations to assess the content of ¹³⁷Cs and mutagenicity tests (bone marrow micronucleus test and sperm

abnormality assay) were performed. The results obtained showed a positive correlation between the increase of micronucleated polychromatic erythrocytes (MPCE/1000 PCE) and both ¹³⁷Cs content in muscle and in soil contamination. The estimated doses absorbed by the animals were far lower than those required for the same effect in laboratory experiments. An explanation of this discrepancy between dose and measured biological effect is not available, yet similar results have been repeatedly reported after the *Chernobyl* accident and should be a matter for further discussion. An increased frequency of micronucleated cells might occur at minimal dose gradients, and the micronucleus test appears to be a valid tool to show such effects. Author-abstract.

JT CANADIAN JOURNAL OF MICROBIOLOGY.

PT JOURNAL-ARTICLE (ART).

AB The accumulation of radioactive Cs by fungi was studied by analysis of fruit bodies (n (total) = 205, n greater than or equal to 5 for 22 species) collected in 1988 in a Norwegian mountain area with high deposition of radiocaesium from the *Chernobyl* accident. To account for site variation, the radiocaesium content of soil and plants was determined for each sampling spot. The soil contained 5-600 kBq/m² (median = 50 kBq/m², ¹³⁴Cs + ¹³⁷Cs). The plant content ranged from 0.25 to 23 Bq/g dry weight (median = 3.1 Bq/g) and was positively correlated with radiocaesium concentration in the soil (r = 0.56) and negatively correlated with soil pH (r = -0.28). The ratio between radiocaesium content in fungi and that in plants at the same spot (F/P) differed among species: 25 species had F/P values between 30 and 270, 12 species had F/P values between 10 and 30, and the rest (16 species) had F/P values below 10 (only four samples had values below 1). The concentration of nonradioactive Cs in fruit bodies was positively correlated with their radiocaesium content. Certain species selectively accumulated one or several trace elements (V, Cd, Hg, Pb, Th). Author-abstract.

AB Pregnancy outcome was studied in a county in Norway 3 years prior to and 3 years subsequent to the *Chernobyl* nuclear plant accident on 26th April 1986. More detailed analyses have been performed for the 12 months prior to and subsequent to the accident. A significant increase in the spontaneous abortion rate the first year after the accident was followed by a slight decrease during the second and third years, but figures were still higher than the period prior to the accident. The rate of legal abortions was unchanged. During the entire observation period the number of births increased continuously, with the exception of a decrease in the last 2 months of 1986 and the first month of 1987. A higher incidence of spontaneous abortions was found for pregnancies conceived during the first 3 months after the accident. This increase in the spontaneous abortion rate is noteworthy, and more especially its long-term persistence, which cannot be the result of external radiation. The internal radiation from food polluted by radioactive fallout is a possible explanation. Changes in nutrition in order to avoid polluted food may also be of importance. Author-abstract.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).

AB Nuclear energy's share of the world electricity market has been growing over the past 35 years. In 1989, eight generating units entered commercial operation abroad and three new units were licensed in the U.S. In early 1990, Mexico became the 26th country to produce electricity from nuclear power. Currently the 426 operating reactors supply one sixth of the world's total electrical capacity. Fourteen countries have now operated nuclear plants for 20 or more years. Since 1980, France has been the leader in the use of nuclear power and currently generates three quarters of its electricity from 54 nuclear plants. The U.S. has 112 nuclear plants, the largest number of any country in the world. These plants satisfy almost 20 percent of U.S. electrical energy requirements. Last year Three Mile Island, the would-be icon for everything that is wrong with the nuclear industry was rated as the most efficient nuclear plant in the world. The worldwide trend toward acceptance of nuclear is improving slightly, but many political and societal issues need to be resolved. Whereas recent polls indicate that a majority of the people realize nuclear must be a major contributor to the energy mix of the future, many are reluctant to support the technology until the issue of waste disposal has been resolved. Fears of another *Chernobyl,* lack of capital, and a new anti-nuclear campaign by Greenpeace will keep the nuclear debate alive in many countries. Additional stumbling blocks in the U.S. include the need to develop a new generation of improved reactor designs which emphasize passive safety features, standardized designs and a stream-lined federal licensing process. Nuclear power is really not dead. Even environmentalists are starting to give it another look. A nuclear renaissance will occur in the U.S. How soon or under what conditions remain to be seen. The next crisis in the U.S. will not be a shortage of energy, rather a shortage of electricity.(ABSTRACT TRUNCATED AT 250 WORDS). Author-abstract. 42 Refs.

JT RISK ANALYSIS.
PT JOURNAL-ARTICLE (ART).
AB Assessments of public perceptions of the characteristics of a nuclear power plant accident and affective responses to its likelihood were conducted 5 months before and 1 month after the *Chernobyl* accident. Analyses of data from 69 residents of southwestern Washington showed significant test-retest correlations for only 10 of 18 variables--accident likelihood, three measures of impact characteristics, three measures of affective reactions, and hazard knowledge by governmental sources. Of these variables, only two had significant changes in mean ratings; frequency of thought and frequency of discussion about a nearby nuclear power plant both increased. While there were significant changes only for two personal consequences (expectations of cancer and genetic effects), both of these decreased. The results of this study indicate that more attention should be given to assessing the stability of risk perceptions over time. Moreover, the data demonstrate that experience with a major accident can actually decrease rather than increase perceptions of threat. Author-abstract.

AB The *Chernobyl* accident has marked the beginning of a new stage of radiobiology development and revealed scantiness of old concepts. One should (1) search for effective protectors against the long-term influence of low-level radiation and means of removal of radionuclides using criteria that differ principally from those used previously in selecting among nontoxic antioxidants, immunomodulators, and adaptogens; (2) study systematically the synergism of low doses of harmful agents and review the hygienic standardization system with due regard for the risk from their combinations; (3) consider comprehensively, on the basis of the experimental and clinical experience, the problem of "hot" particles and remote consequences of their influence on the respiratory and digestive systems; (4) study independently the problem of chronic stress as a combination of radiation effects and psycho-emotional consequences of the accident and living in the exposed areas; (5) consider it inadmissible to include in the B category the population of the districts influenced by the accident and to use the concept:

"35 rads during the lifetime" in standardizing the radiation load;
(6) organize a comprehensive analysis of the *Chernobyl* accident consequences for public health within the contaminated areas as well as for animals and plants using a single approved methodology and programme, the principle of "other equal conditions" being provided.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-MULTICASE (RMC).

AB The nuclear accident at *Chernobyl* accounted for an acute radiation syndrome in 237 persons on the site. Triage was the initial problem and was carried out according to clinical and biological criteria; evaluating the doses received was based on these criteria. Thirty one persons died and only 1 survived a dose higher than 6 Gy. Skin radiation burns which were due to inadequate decontamination, greatly worsened prognosis. The results of 13 bone marrow transplantations were disappointing, with only 2 survivors. Some time after the accident, these severely irradiated patients are mainly suffering from psychosomatic disorders, in the USSR, some areas have been significantly contaminated and several measures were taken to mitigate the impact on population: evacuating 135,000 persons, distributing prophylactic iodine, establishing standards and controls on foodstuff. Radiation phobia syndrome which developed in many persons, is the only sanitary effect noticed up to now. Finally, in Europe, there was only an increase in induced abortions and this was totally unwarranted. If we consider the risk of radiation induced cancer, an effect might not be demonstrated. PT JOURNAL-ARTICLE (ART).

AB In the Finnish environment, lakes provide very important transfer pathways for various pollutants. In this study, a large watercourse was modeled using the dynamic compartment model DETRA. The model includes a fish model for roach, nonpredatory and predatory perches, and pike. Transfer of ^{137}Cs fallout deposited onto the Kymijoki drainage area after the *Chernobyl* accident was calculated using the model. In the model, fallout was assumed to consist of a soluble and insoluble component, behaving differently in the environment. Model predictions were compared with measured concentrations. Lake Paijanne, the largest lake of the watercourse, was studied most extensively. Calculated concentrations in lake water were consistent with measured concentrations. However, calculated concentrations in fish were lower than measured concentrations. To test the model by using additional experimental data, transfer of nuclear weapons testing fallout was also calculated. The processes that cause the rather rapid removal of ^{137}Cs from lake water need to be studied further using more detailed data. In the long term, runoff and resuspension of sedimentary material were considered to be important in causing concentrations in lake water. Author-abstract.

AB Radioactive contamination of wild-growing mushrooms collected in the Northern Black Forest and neighbouring Rhine Valley area has been monitored since the *Chernobyl* reactor accident. Cs-134, Cs-137, Ag-100m and the natural nuclide K-40 were determined by gamma-spectrometry. Pooled data from all species and all locations showed a decrease in the radio-caesium levels from 1986 to 1988, both in mean values and maximum values. Samples of the same species collected at the same location exhibited large differences, although mixed samples rather than individual mushrooms were measured.

Accumulation of caesium was observed particularly in *Laccaria amethystina*, *Xerocomus badius*, *Xerocomus chrysenteron*, *Cantharellus tubaeformis*, *Laccaria laccata*, and *Russula ochroleuca*, with maximum values of 3600 (1986), 2000 (1987), and 1200 (1988) Bq/kg of radiocaesium. A large number of species, among them *Calocybe gambosa* and *Coprinus comatus*, showed very small accumulations or no caesium. An accumulation of silver was found in *Macrolepiota rhacodes* and *Agaricus arvensis*, which contained a maximum of 11 Bq/kg Ag-110m. Author-abstract.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).

AB Two topics relating to radioactivity and food are discussed: food irradiation for preservation purposes, and food contamination from radioactive substances. Food irradiation involves the use of electromagnetic energy (x and gamma rays) emitted by radioactive substances or produced by machine in order to destroy the insects and microorganisms present and prevent germination. The sanitary and economic advantages of treating food in this way are discussed. Numerous studies have confirmed that under strictly controlled conditions no undesirable changes take place in food that has been irradiated nor is radioactivity induced. Reference is made to the accident at the *Chernobyl* nuclear power station, which aroused public concern about irradiated food. The events surrounding the accident are reviewed, and its consequences with regard to contamination of different foods with radioactive substances, particularly iodine-131 and cesium-137, are described. Also discussed are the steps that have been taken by different international organizations to set limits on acceptable radioactivity in food. Author-abstract. 15 Refs.

SO Health-Phys. 1990 Aug. 59(2). P 189-92.

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB Transfer of radiocesium from vegetation to milk was studied in dairy goats grazing heavily contaminated mountain pasture in southern Norway in the years following the *Chernobyl* accident. Radiocesium activity in milk and green vegetation remained stable throughout 1986 and 1987. In 1988, a sudden three- to fivefold increase in milk radioactivity occurred during the second half of the summer. Whole-body content of radioactivity in sheep and reindeer also increased rapidly. This coincided with an abundant growth of fungal fruit bodies with radiocesium levels up to 100 times higher than green vegetation. Fungal radiocesium was found to be highly available in a digestibility study with goats. Milk radioactivity levels in the field could be accounted for by consumption of as little as 20-100 g d-1 of fungal dry matter (DM). The importance of fungal fruit bodies in transferring radiocesium to ruminants was further substantiated by comparing meat activities in grazing

ruminants in 1988 and 1989. Fungal fruit bodies were present in minor quantities in 1989, and radioactivity levels in sheep and reindeer in August-September were only 28-35% of those in 1988. This ability of fungi to mobilize radiocesium from natural soils and transfer the isotopes into the human food chain greatly enhances the vulnerability of food production in natural ecosystems to radiocesium pollution. JT SCIENCE OF THE TOTAL ENVIRONMENT.
PT JOURNAL-ARTICLE (ART).
AB Radiocaesium contamination of dusts from external (road and school yards) and internal (house) environments within Barrow-in-Furness was found to be derived from the primary input event of *Chernobyl* fallout. The specific activity of radiocaesium in the dust reservoirs studied, decreased exponentially, enabling environmental half-lives to be calculated (190-370 day). The broad similarity of these half-lives indicated that secondary contamination processes, such as atmospheric deposition of resuspended dust, cause all the internal and external reservoirs to be linked into a system encompassing much of Barrow-in-Furness. Mean residence times of external dust were derived from the calculated environmental half-lives and measurements of atmospheric deposition (150-250 day). These mean residence times are dependent on local processes and are thus site specific, whilst the environmental half-lives represent an integration of all the processes operating in Barrow-in-Furness. AB An investigation of 25,000 samples of foodstuffs and feedstuffs in Czechoslovakia, contaminated by fall-out cesium after the accident in the *Chernobyl* nuclear power plant, performed from May 5, 1986 to March 31, 1988, revealed that both the values of cesium transfer-factors in food--animal tissues--milk transitions and the values of biological half-life of cesium are functions of internal

and external conditions of contamination. Organism individuality as the main internal condition causes the variance of about $\pm 50\%$ of the mean value of the respective transfer-factor. Through the external conditions, mainly the environmental contamination level, type of ingested food and time of ingestion, the mean values of transfer-factors are influenced up to 500%, e.g. to the value of 0.5. But this value converges with growing up contamination of food and environment to the limit of 0.3. The first two to three biological half-lives after the last ingestion of contaminated food are up to ten-times shorter than those at stabilized state.

AB After the *Chernobyl* accident serious concern spread throughout Italy about the possible effects of the consequent exposure to radioactivity on fetuses. A reduction of births in the first three months of 1987, and particularly in February (7.2% reduction in the birth rate), was observed throughout Italy. In m. Samples of soil, vegetation, milk, and water from this area contained higher than normal concentrations of ^{129}I . The long-term transfer of radioiodine from the soil to the plant and the translocation within the soil were studied using a soil monolith with a ^{129}I -contaminated surface. During the 4 y of the experiment, the transfer factor plant/soil decreased from 0.3 to 2.2×10^{-3} . Soil samples taken in 5-cm steps to a depth of 30 cm then at 40 and 50 cm depths showed that the transport of radioiodine to lower layers proceeds very slowly. The top 5-cm layer contained about 80% of the total radioactivity 52 mo after contamination. In an in-vivo study with a dairy cow, the transfer of radioiodine from feed to milk to cow meat and to pig thyroid gland was followed for 53 d using ^{129}I -labeled pasture grass contaminated via roots. A part of the milk obtained from the cow was fed to a pig as a substitute for humans. The mean value of the transfer factor milk/feed was 2.4×10^{-3} d kg⁻¹. The values of the transfer factor cow meat/feed obtained for different muscle cuts and organs (excluding thyroid) ranged between 3.0×10^{-4} (kidney) and 5.4×10^{-2} d kg⁻¹ f.w. The transfer factors pig thyroid/milk (as pig feed) and pig thyroid/cow feed exhibited values of 1.2 and 8.7×10^{-3} d kg⁻¹ f.w., respectively. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB The disastrous accident at the nuclear power station at the *Chernobyl* on 1986 (April 26) has brought attention to the estimation of radiation health effects and many "experts" were attending to the evaluation on oncogenic mortality increase among the Italian population in the next future. On the contrary at that time too few peoples were worried about the possibility of detecting such an increase. Discussion of this topic is notoriously fraught with difficulties arising from differences of opinion how to estimate low-dose risk in humans without data from direct observation. One opinion is to extrapolate from the data points obtained at relatively high doses toward zero dose (zero extrapolation theory). This permit estimates of risk to be made but, in the final analysis, no data from humans exist that show that low-level radiation exposures produce measurable biologic effects. For that this theory is more useful in radio-protection and medico-legal subjects. It is easy on a statistical basis to prove the impossibility to establish an increase in human cancer after low doses of ionizing radiation such as those received environmentally after the *Chernobyl's* accident. In this condition to observe the numbers of radiation-induced cancer deaths that far exceed the "natural" incidence would require a follow-up a sample more and more greater than the italian population herself. Indeed the statistical power of a hypothetical follow-up study at a suitable confidence level would require a sample size higher than a milliard of persons for the detection of an increase of a generic cancer mortality and higher then seven hundred of millions for the detection of an increase of the specific thyroid cancer mortality. In more detail the following figures for the parameters needed to curring out the evaluation have been used: medium dose equivalent to the thyroid, 2.03 mSv; medium effective dose equivalent up to december '87, 0.6 mSv; thyroid cancer mortality in the italian population, $0.94 \cdot 10^{-5}$ y⁻¹; total cancer mortality in the italian population, $22.2 \cdot 10^{-2}$ y⁻¹; risk factor per unit dose equivalent in thyroid, $0.5 \cdot 10^{-6}$ mSv⁻¹; risk factor per unit effective dose equivalent, $2.0 \cdot 10^{-5}$ mSv⁻¹. Applying the foregoing values in statistical inference methods it could be achieved that $7.5 \cdot 10^8$ and $1.25 \cdot 10^9$ persons must be followed-up in the next 30 years to detect a significant increase over the "natural" cancer mortality for thyroid and "total body" radioinduced cancers respectively.(ABSTRACT TRUNCATED AT 400 WORDS). PT JOURNAL-ARTICLE (ART).
AB The Institute for Medical Protection of Mothers and Children, being
regional centre of European registry of congenital malformations
(EUROCAT) since 1982, registers congenital anomalies in municipals of
Varazdin and Rijeka. Following the nuclear disaster of *Chernobyl,*
there were numerous articles published mainly in daily newspapers,
pointing to the increased number of malformations, particularly to
Down's syndrome, due to additional irradiation imposed on population.
Through this study we wanted to find out whether in Varazdin and
Rijeka, following the *Chernobyl's* accident, there has been any
increase of congenital anomalies and whether our regional and EUROCAT
registry have been adequate to find out genetic effects of small
doses of ionizing radiation. The total incidence of registered
congenital anomalies in Varazdin and Rijeka in previous four-year
period, amounted to 12.97%, while following *Chernobyl,* it amounted to
12.7%. Not even nine marker malformations, including Down's
syndrome, show any statistically significant increased number of
malformations, a year after this nuclear accident. In 18 EUROCAT
registries, on almost half a million of newly born children and
foetuses, conceived before and after May 1, 1986, the frequency of
Down's syndrome and congenital malformations of central nervous
system and eyes has been compared. There have been no important
differences between two compared groups, and the rate of Down's
syndrome was 1.26% before, and 0.91% after the accident. Anticipated

stochastic genetic effects of measured and estimated additional doses of radiation imposed to our and Western European populations are too small to be found out neither by regional nor by EUROCAT registries. Author-abstract.

JT INTERNATIONAL JOURNAL OF RADIATION BIOLOGY.
PT JOURNAL-ARTICLE (ART).
AB A detailed study was made of the conditions of exposure of 56 victims of the *Chernobyl* accident who suffered radiation lesions in the skin. The most typical conditions were experimentally reconstructed in order to investigate the specific characteristics of the distribution of doses to the skin according to depth for different exposure conditions. The absorbed doses at depths of 7 mg cm⁻² and 150 mg cm⁻² were calculated on the basis of measurements with multilayer skin dosimeters. The patients were classified into four groups. Dosimetric characteristics for each group were compared with the clinical pictures to establish the critical factors in the occurrence of lesions. It was demonstrated that the depth-dose distribution of beta-radiation to the skin is of great influence not only for the early effects of radiation but also for the later effects. Radiation lesions in the skin led to death if the area of the lesions exceeded about 50% of the total body surface, and if the doses to the skin were about 200-300 Gy at 7 mg cm⁻² and more than about 30 Gy at 150 mg cm⁻². AB Today the most important anthropogenic radiation comes from atmospheric testing of nuclear weapons carried out 20-30 years ago, authorized discharges to the sea from nuclear reprocessing plants, and from the *Chernobyl* accident in 1986. In the past decade the International Union of Radioecologists (IUR) has contributed to improved international co-operation among radioecologists from all parts of the world through its creation of a number of working groups for specific radioecological problems. More than 30 years of radioecological studies have probably made the radioactive

contamination of our environment the best-understood of all present pollution problems. This review indicates the doses to man received from the important anthropogenic sources, as well as those from natural background radiation. It appears that in a global perspective the latter is by far the most important contributor. Author-abstract. 10 Refs.

AB Nowadays all people are exposed to mutagens environmentally, occupationally, therapeutically or due to life style. In order to validate any conclusions concerning a possible effect of some kind of these mutagens to the relevant exposed groups, chromosomal analysis was carried out on a standard population (211 persons) distributed randomly from biological and social points of view and on 163 persons, occupationally exposed to different kinds of mutagens.

Analysis proved that the mean frequency of chromosomal aberrations (CA) of control was 0.81% and it was similar before and following the *Chernobyl* events. Data concerning the CA frequency in people exposed occupationally to low doses of ionizing radiations below the internationally accepted permissible level, showed a 2-6-fold increase of aberrant cells. Occupational exposure to chemical mutagens such as vinyl-chloride and organic solvents like benzene and toluene revealed 2-4 times higher frequency of CAs than the control; however, exposures to organophosphorus insecticides reached a 5-6-fold increase in CAs as well. The sister chromatid exchange (SCE) frequency data were in each exposed group higher than the control values. Neither chromosomal aberration frequencies, nor sister chromatid exchanges differed significantly between smokers and non smokers in control and exposed persons. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB This paper concerns risk perceptions of Swedish Saami reindeer herders in conjunction with the *Chernobyl* nuclear disaster. Focus is

also placed upon their experiences of damage and their efforts to deal with these problems. Data relating to these social aspects of the *Chernobyl* event come from interviews with members of Saami herding families. The initial governmental policy of establishing a simple contamination limit for the marketability of all foodstuffs was beset with shortcomings. I propose that all contaminated foods should be labeled with contamination specifications along a fully graded scale. In addition, there should be consumer education and recommendations for the entire population, not just one segment. An absolutely necessary step in the construction of valid policies is the health calibration of low-dose radiation. Without such knowledge, any marketability limit is suspect. With such knowledge, policy can be firmly based on human health. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB A considerable number of irradiated persons appeared as a result of the accident at the *Chernobyl* Atomic Power Station. Analysis of chromosome aberrations and detailed hematological investigations were performed in them. Relatively uniform affection of the hemopoietic tissue could be anticipated on the basis of the results of the cytogenetic analysis in most of these persons who had been exposed to radiation at doses that were critical for the development of the bone marrow syndrome. It made it possible to establish direct quantitative relationship between the indices of a postradiation curve of the time course of the neutrophil count in peripheral blood and the mean rate of dicentrics in lymphocytes for cases of relatively uniform irradiation and to plot prognostic curves of neutrophils for different frequencies of dicentrics. JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB Strontium-90 is of relevant biological importance among fission products released during a fission reactor accident. Rapid

information on its concentration in environmental matrices is extremely valuable, yet this implies chemical separations and handling with a shift in daughter equilibrium and therefore the need to wait a sufficient time for the equilibrium to be reestablished. The work concerns a feasibility study of a multi-detector system for a prompt evaluation of the ^{90}Sr activity or, at least, a prompt determination of its order of magnitude in the presence of other pure beta and beta-gamma emitters; their interferences are examined on the basis of the *Chernobyl* releases and their decay properties. The technique is based on a plastic scintillator beta detector and a guard ring of BGO counters which can be logically connected in coincidence and anticoincidence. The evaluations show that a few hours are sufficient to determine a specific activity comparable with the Maximum Permissible Concentration in air by sampling 10 m^3 .

PT JOURNAL-ARTICLE (ART).

AB The United Nations Scientific Committee on the Effects of Atomic Radiation (UNSCEAR) has published a substantive series of reports concerning sources, effects, and risks of ionizing radiation. This article summarizes the highlights and conclusions from the most recent 1986 and 1988 reports. The present annual per person effective dose equivalent for the world's population is about 3 mSv. The majority of this (2.4 mSv) comes from natural background, and 0.4 to 1 mSv is from medical exposures. Other sources contribute less than 0.02 mSv annually. The worldwide collective effective dose equivalent annually is between 13 and 16 million person-Sv. The Committee assessed the collective effective dose equivalent to the population of the northern hemisphere from the reactor accident at *Chernobyl* and concluded that this is about 600,000 person-Sv. The Committee also reviewed risk estimates for radiation carcinogenesis which included the new Japanese dosimetry at Hiroshima and Nagasaki. These data indicate that risk coefficient estimates for high doses and high dose rate low-LET radiation in the Japanese population are approximately 3-10% Sv⁻¹, depending on the projection model utilized. The Committee also indicated that, in calculation of such risks at low doses and low dose rates, a risk-reduction factor in the range of 2-10 may be considered. Author-abstract.

AB This article describes the nutritional measures introduced to protect
health after the *Chernobyl* accident, and the associated costs. The
total value of the reindeer meat, mutton, lamb and goat meat saved as
a result of such measures in 1987 amounted to approx. NOK 250
million. The measures cost approx. NOK 60 million. The resulting
reduction in the radiation dose level to which the population was
exposed was 450 manSv. In 1988, mutton/lamb and goat meat valued at
approx. NOK 310 million was saved from condemnation by similar
measures, which cost approx. NOK 50 million. The resulting dose
level reduction was approx. 200 manSv. The relationship
(cost/benefit ratio) between the overall cost of the measures taken
to reduce radioactivity levels in food and the dose level reduction
achieved was acceptable. Author-abstract.

JT TIDSSKRIFT FOR DEN NORSKE LAEGEFORNING.

PT JOURNAL-ARTICLE (ART).

AB The outcome of pregnancies in six countries in Norway has been studied during 12 months prior and subsequent to the *Chernobyl* accident. The accident took place in a period with an annual increase of births of approximately 3%. However, the year after the accident a decrease of 0.7% was observed with particularly low numbers during February--April 1987. Concomitantly, the miscarriage fraction of all pregnancies increased by 16.3% and particularly during November 1986--January 1987. The same pattern was found when observations from Haukeland Hospital were analyzed separately. When the time of conception was taken into consideration we found that conceptions during the period May--July 1986 ended more often as miscarriages. We have no explanation of the observations. The external radiation exposure seems too small to have produced these effects. The internal radiation from food may have played a role. People may also have changed their food intake, using less vegetables, due to fear of these being polluted by radioactive fallout. Author-abstract.

PT JOURNAL-ARTICLE (ART).
AB The temporal variations of radionuclide ratios in air and deposition
samples collected simultaneously at Munich-Neuherberg (F.R.G.) after
the *Chernobyl* accident have been studied. Until 8 May 1986, the
radionuclides investigated were ⁹⁹Mo, ¹⁰³Ru, ¹⁰⁶Ru, ^{110m}Ag, ¹²⁵Sb,
^{129m}Te, ¹³²Te, ¹³¹I, ¹³⁴Cs, ¹³⁷Cs, ¹⁴⁰Ba, ¹⁴¹Ce and ¹⁴⁴Ce. After 8
May, ⁹⁹Mo, ^{110m}Ag, ¹²⁵Sb, and the Ce isotopes were below the
detection limits. Considerable temporal variations of the above
radionuclides, relative to ¹³⁷Cs, were observed in air as well as in
deposition. In air the temporal variations reflect the arrival of
different parts of the reactor plume with different elemental
composition. In deposition, the temporal patterns were quite
different from those in air for a given radionuclide. This is
explained by varying contributions of dry and wet deposition. Until
8 May, the washout ratios of the above radionuclides covered a range

from 240 to 5600, with smaller variations for all radionuclides within one event (e.g. 460-910), and larger variations from one event to another (e.g. 460-3300 for ^{137}Cs). The dry deposition velocity of ^{137}Cs was found to be 0.27 cm s^{-1} , similar to that of ^{110m}Ag , aerosol ^{131}I and ^{140}Ba (0.37 , 0.13 and 0.15 cm s^{-1}). Another group of radionuclides includes ^{103}Ru , ^{106}Ru , ^{125}Sb , total ^{131}I and ^{132}Te with dry deposition velocities of 0.08 , 0.10 , 0.07 , 0.03 and 0.08 cm s^{-1} and with temporal variations in deposition which are quite different from those of the first group. From 8 May to the end of June, the washout ratios increased to values between 1500 and 24,000, with the exception of iodine, which had considerably lower washout ratios of between 37 and 4400. These later effects are explained by resuspension and, in the case of iodine, by remobilization of gaseous species. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB After spraying grass cultures with rainwater collected after the *Chernobyl* reactor accident, the time-dependence of the weathering of leaf contamination of ¹³⁴/¹³⁷Cs was determined. Hereby the influence of rain and of biomass increase due to growth was considered. Two effective half-lives were found of 6 d and more than 60 d in rain-protected grass for the activity per area (corresponding to 8 d and more than 60 d when related to the activity per dry weight) and 2 d and 30 d in rain-exposed grass for the activity per area (3 d and 23 d when activity per dry weight is considered). These half-lives represent the initially rapid (for about 90% of the activity) and later slow (for the residual about 10%) decrease of the Cesium content in grass. They might be due to different weathering mechanisms whereby the translocation of the radionuclides from the leaf surface into the plant interior and the loss of wax particles might be of importance. JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB In order to estimate the contribution of ^{90}Sr to the exposure of the Austrian population, the ratio of ^{90}Sr to ^{137}Cs in 126 food samples and nine drinking water samples was determined. From this and the average activity concentration of ^{137}Cs in each type of food as obtained by the measurement of some 100,000 food samples after the *Chernobyl* accident, a good estimate of the average activity concentration of ^{90}Sr in these food items could be obtained. Samples were investigated at various times after the accident to take into account possible changes with time in the ^{90}Sr -activity concentration and its ratio to ^{137}Cs . Also, *pre-Chernobyl* samples were measured to estimate the relative contribution of the reactor accident and the fallout of the atomic bomb testing to the intake of ^{90}Sr . Assuming average food consumption, the intake of ^{90}Sr for an adult person amounted to 168 Bq in the first year and 115 Bq in the second year after the accident, resulting in an effective dose equivalent of 5.9 μSv and 4.0 μSv , respectively. This is a minor fraction of the dose due to the ingestion of Cs isotopes, which amounted to 360 μSv in the first year and 97 μSv in the second year. For the one-year-old infant, a ^{90}Sr intake of 96 Bq (10.5 μSv) in the first year and 65 Bq (7.1 μSv) in the second year is estimated. Approximately 50% of the intake in the first year and 70% of that in the second year are due to ^{90}Sr from nuclear weapons testing. Author-abstract.

TI Acute effects of the *Chernobyl* nuclear accident on Irish mortality?

SO Ir-Med-J. 1989 Sep. 82(3). P 119-21.

JT IRISH MEDICAL JOURNAL.

PT JOURNAL-ARTICLE (ART).

AB This report examines the claim that Irish mortality in the second quarter (April-June) of 1986 increased due to the cloud of radioactive material released by the damaged reactor in *Chernobyl.* Over the period 1971-1987, based on date of registration, the death rates in the second quarter showed marked year to year variation often exceeding that expected on the basis of chance alone. In 1986 the percentage of annual deaths occurring between April and June, and the death rate itself, were both significantly higher than in most other years between 1981 and 1987. The 1986 figures were not however, significantly higher than those observed in years prior to 1981. Since the distribution of mortality by cause was not consistent with the hypothesis relating low level radiation to immediate mortality, and since causality cannot be inferred from a temporal association per se, the *Chernobyl* accident cannot be implicated in the excess mortality observed in the second quarter of 1986. SO Health-Phys. 1989 Nov. 57(5). P 697-706.

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB The *Chernobyl* source term available for long-range transport was
estimated by integration of radiological measurements with
atmospheric dispersion modeling and by reactor core radionuclide
inventory estimation in conjunction with WASH-1400 release fractions
associated with specific chemical groups. These analyses indicated
that essentially all of the noble gases, 60% of the radioiodines, 40%
of the radiocesium, 10% of the tellurium, and about 1% or less of the
more refractory elements were released. Atmospheric dispersion
modeling of the radioactive cloud over the Northern Hemisphere
revealed that the cloud became segmented during the first day, with
the lower section heading toward Scandinavia and the upper part
heading in a southeasterly direction with subsequent transport across
Asia to Japan, the North Pacific, and the west coast of North
America. The inhalation doses due to direct cloud exposure were
estimated to exceed 10 mGy near the *Chernobyl* area, to range between
0.1 and 0.001 mGy within most of Europe, and to be generally less
than 0.00001 mGy within the United States. The *Chernobyl* source term
was several orders of magnitude greater than those associated with
the Windscale and TMI reactor accidents. However, the ¹³⁷Cs from the
Chernobyl event is about 6% of that released by the U.S. and
U.S.S.R. atmospheric nuclear weapon tests, while the ¹³¹I and ⁹⁰Sr

released by the *Chernobyl* accident was only about 0.1% of that released by the weapon tests. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB Three types of activity composition have been found in airborne hot particles that were transported long distances from the *Chernobyl* accident. Their characterization is based on the analysis of single particles isolated from Pinus Sylvestris needles. The average

activity of the particles was 130 Bq at the time of the accident. The most common type of particle contains the radioactive species ^{141}Ce , ^{144}Ce , ^{95}Zr and ^{95}Nb ; the second type includes ^{103}Ru and ^{106}Ru along with the previous isotopes; and the third contains ^{103}Ru and ^{106}Ru only. Cesium-134 and -137 were present only in very small amounts. The activity composition of the *Chernobyl* reactor core fuel was similar to the composition of the first and second type particle; apparently the core fuel was only partially volatilized. The main bulk composition of the particles is shown to be U. The average aerodynamic size of the identified hot particles is 10 microns. The particles are rectangular or pentagonal in shape. SO Health-Phys. 1989 Dec. 57(6). P 967-73.

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB Following the *Chernobyl* accident in April 1986, the transfer of ^{131}I and ^{137}Cs from feed to milk was studied under experimental and common agricultural conditions. From measurements in different dairy farms in Southern Bavaria, equilibrium transfer coefficients for cow's milk were calculated to be 0.003 d L^{-1} (range 0.0015 to 0.005) for ^{131}I and 0.003 d L^{-1} (range 0.0025 to 0.004) for ^{137}Cs . In feeding experiments with cows and sheep under more controlled conditions, milk transfer coefficients of 0.007 d L^{-1} (range 0.0055 to 0.0081) for ^{131}I and 0.003 d L^{-1} (range 0.0023 to 0.0053) for ^{137}Cs were obtained for cows, while for sheep the ^{137}Cs transfer coefficient was higher: 0.06 d L^{-1} . The kinetics of the Cs transfer from fodder to cow's milk can be described by two exponential terms assuming biological half-lives in milk of 1-2 d and 10-20 d. The use of a fast component with 1.5 d and a fraction of 0.8, and a slow component with 15 d, gives a good approximation to the kinetics for all cows in this experiment. Author-abstract.

SO Health-Phys. 1989 Dec. 57(6). P 959-66.

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB Cesium-137 and 40K concentrations were measured in vegetation and in red-backed voles (*Clethrionomys gapperi*) in southeastern Manitoba, Canada, following the *Chernobyl* accident in 1986. Voles from wet coniferous habitats contained concentrations of 137Cs twenty- to fiftyfold higher than voles from deciduous habitats. Maximum 137Cs values were observed in autumn. Voles captured in a spruce bog at this time contained an average body burden of about 11 Bq. Concentrations in vegetation samples were similar to those found by other researchers. Overall, there was only minimal evidence of contamination attributable to *Chernobyl* in either vegetation or voles. The primary source of 137Cs in voles appeared to be dietary, particularly mushrooms that contained up to 74 Bq g⁻¹ ash. Based on physiological constraints, mushrooms were the only plausible source of 137Cs in autumn diets. Elevated values at other times in coniferous areas may have been related to the consumption of epiphytic lichens. These findings suggest that fungi, or the animals that consume them, can serve as sensitive indicators of 137Cs contamination in the environment. Author-abstract.

SO Sci-Total-Environ. 1989 Sep. 85. P 81-90.

JT SCIENCE OF THE TOTAL ENVIRONMENT.

PT JOURNAL-ARTICLE (ART).

AB The transfer of Ag-110m from the *Chernobyl* fallout to sheep tissues is discussed. Ag-110m was only detected in the liver and occasionally the brain of the sheep analysed. The transfer of Ag-110m associated with perennial rye-grass, harvested soon after deposition in 1986, was greater to the liver of both ewes and lambs than that of Cs-137. Transfer coefficients of Ag-110m for lamb liver exceeded those for ewe livers. However, in a 1987 field study there was no difference between transfer coefficients of Ag-110m for ewes and lambs. It is suggested that there is a slow turnover of Ag-110m in the liver of sheep and that unlike radiocaesium, Ag-110m from the *Chernobyl* fallout did not become more available once incorporated into plant tissues. TI Countermeasures for reducing the transfer of radiocesium to animal
derived foods.

SO Sci-Total-Environ. 1989 Sep. 85. P 317-27.

JT SCIENCE OF THE TOTAL ENVIRONMENT.

PT JOURNAL-ARTICLE (ART).

AB The nuclear reactor accident in *Chernobyl* stimulated new discussions and experiments on the question, how and to what extent the radiocesium-concentration in animal derived foods can be reduced. In a brief review this paper describes the use of two groups of feed additives as already applied in laboratory experiments during the period of atmospheric atomic weapons tests to prevent radiocesium absorption in the gastro-intestinal tract: 1) Iron (III) -Hexacyanoferrates and 2) Clay minerals. In the *post-Chernobyl-period* pilot studies were initiated to test similar feed additives under practical farming conditions with "naturally" radiocesium-labeled feedstuffs. Since then it is obvious that the colloidal Prussian blue analogue Ammonium-Ferric-Cyanoferrate (AFCF) can be considered as a leading antidote against radiocesium, while Bentonite or Bolus alba are 88-266 times less effective, when compared on a weight basis. Additionally clay materials cause losses of minerals and trace elements and pose logistic problems when feeding millions of large animals. Because of the small doses needed AFCF appears as a substance of choice to reduce radiocesium burdens in animal derived foods, which gained full recognition by health authorities in W-Germany and Austria supported by an official clearance for the use as feed additive. SO Sci-Total-Environ. 1989 Sep. 85. P 307-16.

JT SCIENCE OF THE TOTAL ENVIRONMENT.

PT JOURNAL-ARTICLE (ART).

AB The transfer of radiocaesium from silage, contaminated as a result of the *Chernobyl* accident, to cows milk was studied in a feeding trial at Trawsgoed Experimental Husbandry Farm. Feed and milk samples obtained from the cows were analysed for Cs-137 and Cs-134 during the 124 days cows were fed contaminated silage and for a further 32 days when cows were fed uncontaminated material. The trial also involved the addition of bentonite supplements to the diet of some animals. Supplements of 250 g and 500 g sodium bentonite per day reduced

Cs-137 transfer factors to milk to 0.63 and 0.33 of the control values respectively after 78 days of feeding. No effects of bentonite supplementation on the absorption of other elements were detected. The results for animals not given a supplement are compared with the cow-milk model implemented in the SPADE suite of codes, using both default parameters and input data and parameters derived from the feeding trial. The model overpredicted observed milk concentrations by a factor of 2 to 3. Reasons for this and alternative models are discussed. The sensitivity of the model to parameter selection is also emphasized. Author-abstract.

TI A possible method for estimating the true absorption coefficient for radiocaesium in ruminants.

SO Sci-Total-Environ. 1989 Sep. 85. P 263-6.

JT SCIENCE OF THE TOTAL ENVIRONMENT.

PT JOURNAL-ARTICLE (ART).

AB A method has been described for estimating the true absorption coefficient for radiocaesium. The ratio of the excretion of 137Cs in the faeces to that excreted in the urine was estimated in housed ewes and lambs offered a radiocaesium-free diet for 16-22 days, after previously grazing a pasture contaminated with *Chernobyl* fall-out.

There was a two-fold range in the faeces:urine excretion ratio. The ratios obtained were used to estimate the the faecal ^{137}Cs of endogenous origin from the urinary excretion rates of ewes given diets contaminated with radiocaesium from *Chernobyl* or from marine effluent from BNFL, Sellafield, and hence the true absorption coefficient could be determined. The observed variations in faeces:urine excretion ratios had little effect upon the estimates of true absorption coefficient. Author-abstract.

SO Sci-Total-Environ. 1989 Sep. 85. P 207-12.

JT SCIENCE OF THE TOTAL ENVIRONMENT.

PT JOURNAL-ARTICLE (ART).

AB In an experiment initiated after the *Chernobyl* accident, a herd of reindeer was followed before and after a temporary move from a highly contaminated area (greater than $20 \text{ kBq } ^{137}\text{Cs}/\text{m}^2$) to a less contaminated area (less than $3 \text{ kBq } ^{137}\text{Cs}/\text{m}^2$) of natural pasture. The animals grazed in a highly contaminated area until they were moved to the low contaminated area where they grazed from late November to late April. The level of ^{137}Cs in meat was about $12 \text{ kBq}/\text{kg}$ at the time when the animals were moved (Nov.) to the low contaminated area and it decreased to about $3 \text{ kBq}/\text{kg}$ with an effective half-time of about 1 month, after the animals were moved. In the low contaminated area the fractional transfer, f_m , of ^{137}Cs was determined to be 0.65

d/kg during winter pasture, mainly on lichens, and 0.30 d/kg during summer pasture, in the fields. The actual intake of radiocesium was determined by measurement of ruminal samples from slaughtered animals. The maximal radiation dose to reindeer in Sweden after the *Chernobyl* accident was estimated to less than 200 mSv/a with a dose rate of less than 1mSv/d during the winter period of maximum tissue concentration of radiocesium. PT JOURNAL-ARTICLE (ART).

AB Radionuclides, especially the long-lived ¹³⁷Cs (physical half-life 30 years), are accumulated efficiently in the northern, subarctic, lichen-reindeer-man foodchain. Until the *Chernobyl* accident the fallout nuclides studied originated from nuclear weapons tests. After this accident some fresh fallout was deposited in Finnish Lapland. Lichens grow very slowly and collect nutrients very efficiently from air, rain and snow. During winter the basic fodder plants for reindeer are lichens and some winter-green plants, shrubs and dry leaves. During the bare-ground season, the reindeer eat various grasses, herbs and leaves etc. Lichens constitute 30-50 per cent of the entire vegetable mass consumed by the reindeer in a year. The highest ¹³⁷Cs-concentration 2500 Bq/kg dry weight was found in lichen in the middle of the 1960s. In 1985 the concentration had decreased to about 240 Bq/kg dry weight. After the *Chernobyl* accident the ¹³⁷Cs-concentration in lichen varied from 200 to 2000 Bq/kg dry weight in Finnish Lapland. In reindeer fodder plant samples collected in the 1980s before the *Chernobyl* accident the ¹³⁷Cs-concentration varied from 5 to 970 Bq/kg dry weight. The highest ¹³⁷Cs-concentration in reindeer meat, about 2500 Bq/kg fresh weight, was found in 1965 and thereafter decreased to about 300 Bq/kg fresh weight in the winter before the *Chernobyl* accident. After the accident the mean ¹³⁷Cs-concentration in reindeer meat from the 1986-87 slaughtering period was 720 Bq/kg fresh weight and in 1987-88, 630 Bq/kg fresh weight. Author-abstract.

JT SCIENCE OF THE TOTAL ENVIRONMENT.

PT JOURNAL-ARTICLE (ART).

AB The transfer of *Chernobyl* Cs-134 and Cs-137 to milk in dairy cows

from a diet, predominated by silage, was studied under normal farming conditions. The study was carried out in the period December 1986 till August 1987 and comprised three periods with different levels of radioactive contamination of the silage. Transfer coefficients for both radionuclides were derived from measured radiocaesium concentrations in the diet components and in mixed milk samples. Average silage intake was calculated on basis of total need which depends on milk production. The transfer coefficients calculated for Cs-134 and Cs-137 after a 6 weeks feeding period of high-level *post-Chernobyl* silage were 0.26 and 0.27% d/l, respectively. These results indicate that a transfer coefficient of 1.2% d/l, from tracer and fallout studies and recommended for predictive purposes, is a conservative estimate in view of the *post-Chernobyl* experience. The transfer of caesium isotopes from silage to milk in dairy cows is dynamically described with a simple two-compartment model of Pelletier and Voilleque. The most important choices of parameter values to be made in matching calculated and measured concentrations in milk, are those for F and u/m. F is the fraction of ingested activity that is excreted in milk plus urine, and u/m is the ratio between the transfer rates to urine and milk, respectively. The study was carried out with financial support from the Dutch Ministry of Agriculture and Fishery. Author-abstract.

JT SCIENCE OF THE TOTAL ENVIRONMENT.

PT JOURNAL-ARTICLE (ART).

AB Deposition of radiocaesium from the *Chernobyl* reactor accident on the Netherlands made it possible to collect contaminated fresh grass and first cut wilted grass silage. These contaminated roughages were used in transfer experiments with lactating dairy cows to determine transfer coefficients and half-lives for Cs-137 in milk. The experimental design was based on three consecutive periods: a preliminary period to determine the background concentration of the isotope in milk, a contamination period to determine the magnitude of accumulation and finally a depletion period to measure the rate at which the activity concentration of Cs-137 in milk declined after continuous feeding. The average transfer coefficient (F_{milk}) for cows fed on contaminated dried grass under steady-state conditions

was 0.002 d/kg and for cows fed on slightly contaminated second cut fresh grass 0.006 d/kg. The highest transfer coefficients were obtained for cows fed on contaminated grass silage for 119 days, which also included the dry period of about two months. For the first five days after calving the Fmilk values varied from 0.0066 to 0.0091 d/kg. There were no significant differences in transfer coefficients between cows in early lactation (third month of lactation), cows in late lactation (the last month of the lactation period) and cows fed on both contaminated grass silage and uncontaminated maize silage simultaneously. Half-life values for the rate of decline of the isotope in milk during the depletion period were estimated on the basis of a mathematical model with two exponential components. These components were characterized by half-lives of 0.5 to 3.5 days and 10 to 46 days. Author-abstract.

AB The transfer of Cs137 from grass and silage to milk has been followed in detail for one farm in West Cumbria over the year following the deposition from the *Chernobyl* reactor accident. At this farm about 40% of the Cs137 in milk was attributed to the feeding of silage during the following winter. A wider study of an additional 14 farms showed considerable variations in the contributions from grazing and silage. The transfer quotient from silage to milk was comparable with the values measured for grass over the first few weeks and lower than values reached later in the grazing season. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB The release of activity from the *Chernobyl* nuclear reactor resulted in deposition of radionuclides throughout the UK in early May 1986. Since that time, the transfer of radiocaesium from feed to milk has been followed at two farms that differ in both location and husbandry practice. This paper concerns the winter of 1986/87, when activity concentrations in milk increased because of the consumption of silage prepared earlier in the year. Silage-to-milk transfer coefficients have been estimated which suggest that, when incorporated into

prepared silage, radiocaesium from *Chernobyl* is less available for transfer to cows' milk than soluble caesium-134 applied directly onto pasture. The measured activity concentrations in milk have been compared with those predicted by the NRPB model FARMLAND; despite differences between the husbandry practice assumed in the model and those observed in practice, the model provides an adequate radiological assessment of the feed-cow-milk pathway after an accidental release of radioactivity. PT JOURNAL-ARTICLE (ART).
AB Studies of reactions and attitudes toward nuclear war have progressed from the use of anecdotal evidence to multi-item psychological measures. Additional psychometric data and substantive results of the Nuclear Attitudes Questionnaire (NAQ; Newcomb, 1986) are reported here. Data from three independent samples of students from the United States collected in 1984, 1986, and 1987 were compared and contrasted. The 1986 data were obtained immediately following the *Chernobyl* nuclear power plant accident. Test-retest reliability of

the NAQ items and subscales was quite high and comparable among samples and established the across-time stability of the measure. There were several secular trends across years on items and subscales, indicating some increased concern about nuclear power (particularly in 1986), but also a general increase in nuclear concerns, fears, and anxiety. Anticipated sex differences were found on many of the NAQ items and subscales. Correlations between the NAQ subscales and the nine SCL-90-R scales (Derogatis, 1977) were consistent for the 1986 and 1987 samples. In latent variable analyses, a general factor of Emotional Distress was significantly correlated with a general factor of Nuclear Anxiety, as well as specifically with nuclear concern and fear for the future.

PT JOURNAL-ARTICLE (ART).
AB The effects of pickle-curing on a decrease in the cesium-nuclides amount in red-deer meat were investigated. This meat was contaminated through ingestion of natural feed in seasons after the fall-out from *Chernobyl* accident. Two pickles were studied: vinegar solution and the same one with added vegetables and spices. The pickle curing was carried out at temperatures of 5 degrees C and 11 degrees C after cutting the meat into little pieces of about 1.5 cm. A decrease in cesium activity was measured by means of gamma-spectrometry at given time intervals after the process was started. It was proved that the efficiency of this process is mostly influenced by replacement of the pickle solution and by the duration of the process. A decrease in the cesium activity of about 80% was achieved without the change of the pickle after seven hours of curing. But after the same time and one pickle solution change, the activity decrease reached more than 90%. No important influence of added vegetables and spices into the pickle nor of the temperature between 5 degrees C and 11 degrees C was observed. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB For three plants from a peat bog (*Trichophorum caespitosum*, *Molinia coerulea*, *Calluna vulgaris*) the concentration of 137Cs, the ratio 137Cs:134Cs, and stable K was determined in intervals of about 14 d

from June to November 1987. The results show that for two grasses, *Trichophorum caespitosum* and *Molinia coerulea* (which have only perennial roots but sprout every year while the old leaves wither), the concentration of ¹³⁷Cs decreased considerably during the growing season (1800-240, respectively, 4000-320 Bq kg⁻¹ dry weight). A remarkably similar behavior was observed for the seasonal variability of K and radiocesium in the two grass species, which resulted in a nearly constant ratio of ¹³⁷Cs:K during the year. In contrast, for the evergreen plant *Calluna vulgaris* (heather) which was contaminated surficially by the *Chernobyl* fallout, the concentrations of K and ¹³⁷Cs were rather constant during 1987 (leaves about 10,000; stems about 5000 Bq kg⁻¹ dry weight), even though radiocesium was taken up by the leaves and transported within the plant. For the two grasses, the plant:soil concentration ratios (CR) were obtained separately for total ¹³⁷Cs, ¹³⁷Cs from the global fallout, and *Chernobyl-derived* ¹³⁷Cs. The CR of ¹³⁷Cs from the global fallout decreased for *Trichophorum caespitosum* from 1.9 in the spring to 0.08 in the autumn, and for *Chernobyl-derived* ¹³⁷Cs from 1.4 to 0.2. For *Molinia coerulea*, a similar behavior was observed. Possible reasons for the seasonal variability of the CR values and the different behavior of ¹³⁷Cs from the global fallout and from the *Chernobyl* debris are discussed.(ABSTRACT TRUNCATED AT 250 WORDS). PT JOURNAL-ARTICLE (ART).
AB Indoor experiments are described that compare the transfer of radiocesium to ewe and lamb tissues from different sources. Lactating ewes were fed either perennial ryegrass contaminated by *Chernobyl* fallout, or saltmarsh vegetation contaminated by marine discharges from the Sellafield reprocessing plant. The transfer to ewe tissues and milk was greater from the *Chernobyl* contaminated herbage than from saltmarsh vegetation. Lambs receiving a mixture of vegetation and milk were given radiocesium from one of the two vegetation sources or from milk obtained from the experimental ewes. Transfer to lamb tissues declined in the order milk greater than *Chernobyl* fallout greater than Sellafield discharge. The radiocesium transfer to lamb tissues exceeded that to ewe tissues. Transfer coefficients for ^{137}Cs in the *Chernobyl* fallout were higher than most previously published figures at 0.12 d kg^{-1} for ewe muscle and 0.50 d kg^{-1} for lamb muscle. The transfer coefficient for ^{137}Cs from ewe milk to lamb muscle was 1.20 d kg^{-1} . Author-abstract.

AB One of the consequences of the *Chernobyl* reactor accident in 1986 was a comparatively high contamination of foodstuffs in Southern Federal Republic of Germany. In order to test radioecological models predicting the radiological consequences of such accidents, several thousand measurements were performed to determine Cs body burdens in members of the public. For the interpretation of these data and as a contribution to the improvement of the available database on the biokinetics of Cs isotopes in humans, we followed a small group of volunteers after their consumption of highly contaminated venison. Intakes, excretion rates and total body activities were measured during a period of more than 200 d. The data obtained were evaluated in terms of a compartment model to derive gastrointestinal uptakes, biological half-lives and dose conversion factors. The resulting uptake factors range from 65-90%, the half-lives of the long-term retention from 45 to 200 d. The majority of the resulting dose conversion factors lie below the values recommended by the ICRP, showing that the ICRP model is a reasonable and safe description of the Cs biokinetics in our study group, while the great variability of the results shows that it is not an accurate representation of the

individual Cs retention. Author-abstract.

AB The levels of *Chernobyl-derived* ^{137}Cs , ^{134}Cs , ^{106}Ru and ^{103}Ru were measured at Thessaloniki, Greece, in air, rain, soil, grass and milk samples for more than 2 years after the accident. The data were analysed in conjunction with ^7Be (produced in the atmosphere by cosmic rays) measurements and show that significant variations were observed, particularly in the spring and in the autumn measurements. In interpreting these variations we took into consideration the tropospheric, or possibly stratospheric, fallout injections into the atmosphere due to the *Chernobyl* accident, nuclear weapons testing or other releases from nuclear reactors operating world-wide. Useful information can be derived for determining the periodicity of global circulation of the fallout radionuclides. Author-abstract.

AB During measurements of radioactivity in some milk samples with liquid scintillation counter (about one year after the nuclear accident of *Chernobyl*) we have observed an increase of the values of scintillation fluid with the passing of time. Although this enhancement is absolutely small (about 2 c.p.m. in 500 min), it is very important for an exact measurement of samples at low counting, as those tested. Our protocol of measure provides for insertion of alternate blanks and samples in the automatic sample-holders of liquid scintillation counter. The values of measurement of samples are taken during the increase phase subtracting the value of blank interpolated on the increasing straight line from c.p.m. of sample. Finally, we report the collected values of the whole radioactivity in some milk samples: at least 5-6 nCi/L contrary to about 1 nCi/L of ^{137}Cs reported by USL. In our opinion it is important to consider the whole radioactivity as measure of the overall biological danger of radioactive samples. In fact, this measurement takes into account also biologically very dangerous radionuclides as ^3H , ^{14}C , ^{90}Sr . Author-abstract.

AB RADIOACTIVE fallout from the *Chernobyl* accident reached Ireland in May 1986 and caused serious concern with regard to its possible effects on health. Reports of a large scale American study claim an almost immediate effect of *Chernobyl* fallout in terms of increased mortality rates. A study of Irish mortality rates reported a substantial increase in numbers of deaths during the three months immediately *post-Chernobyl.* The present study investigates whether there is a statistically significant basis for the reported increase in mortality in Ireland. No discernible evidence was found for increased mortality rates in Ireland during 1986, following the *Chernobyl* accident. The initial report of increased mortality rates was based on provisional mortality registration statistics and not on actual day by day data. Author-abstract.

PT JOURNAL-ARTICLE (ART).
AB The specific activity of 137Cs and 90Sr from the global fallout, as
well as from the fallout after the reactor accident at *Chernobyl,* was
determined in flour, bran and straw from wheat, rye, barley and oats
as well in the corresponding soils (Cambisol). The results show that
the activity of 137Cs, but not of 90Sr, in the plant material was
considerably higher in 1986, and still to some extent in 1987,
compared to 1982. For 137Cs an 90Sr, as well as for most cereal
samples, the activity in the bran and straw was significantly higher
than in the flour. Determination of stable potassium and calcium in
all samples revealed that this enrichment is, to a large extent, the
result of a comparable enrichment of these elements in brans and
straw. The plant/soil concentration ratios, averaged over all
cereals, were for 137Cs (1982 and 1987): flour 0.026 +/- 0.018; bran
0.079 +/- 0.042; straw 0.055 +/- 0.027. For 90Sr (1982, 1986, and
1987): flour 0.19 +/- 0.095; bran 0.70 +/- 0.23; straw 2.35 +/- 0.82.

JT RADIOLOGIA MEDICA.
PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).
AB The authors discuss the problem of radiation damage to the individual
developing in utero, and summarize the information available in the
literature on the subject. Additional risks induced by ionizing
radiations are classified with reference to gestational age and dose
absorbed by the fetus. Such risks concern the possibility of mental
retardation from the 8th to the 15th gestational week, and of
developing a malignant disease from the 3rd to the 15th gestational
week. We report the dose values received by the fetus as a result of
both radiodiagnostic examinations and the *Chernobyl* nuclear accident:
the doses were generally very low, which leads us to the conclusion
that additional risks are of the same order of magnitude as the
fluctuations in the natural congenital malformations. Thus, prenatal
irradiation for diagnostic examinations does not generally represent
a reason to recommend therapeutic abortion. However, it is always
important to carry out a careful evaluation of the dose absorbed by
the fetus and to correctly inform the mother about eventual
radiation-induced risks. Author-abstract. 49 Refs.

PT JOURNAL-ARTICLE (ART).

AB On April 26, 1986, an accident at the *Chernobyl* nuclear power station in the Soviet Union exposed about 200 people to large doses of total-body radiation. Thirteen persons exposed to estimated total-body doses of 5.6 to 13.4 Gy received bone marrow transplants. Two transplant recipients, who received estimated doses of radiation of 5.6 and 8.7 Gy, are alive more than three years after the accident. The others died of various causes, including burns (the cause of death in five), interstitial pneumonitis (three), graft-versus-host disease (two), and acute renal failure and adult respiratory distress syndrome (one). There was hematopoietic (granulocytic) recovery in nine transplant recipients who could be evaluated, six of whom had transient partial engraftment before the recovery of their own marrow. Graft-versus-host disease was diagnosed clinically in four persons and suspected in two others. Although the recovery of endogenous hematopoiesis may occur after exposure to radiation doses of 5.6 to 13.4 Gy, we do not know whether it is more likely after the transient engraftment of transplanted stem cells. Because large doses of radiation affect multiple systems, bone marrow recovery does not necessarily ensure survival. Furthermore, the risk of graft-versus-host disease must be considered when the benefits of this treatment are being weighed.

PT JOURNAL-ARTICLE (ART).

AB Approximately 18 years ago, the authors were able to produce an apparently successful bone marrow transplant by using umbilical cord blood. In view of the *Chernobyl* disaster and the subsequent problems of treatment with marrow transplantation, this study undertook to explore further the potential use of umbilical cord blood as a source of marrow cells. Specimens of umbilical cord blood were collected

from 13 routine obstetrical deliveries. All specimens grew erythroid and granulocytic-monocytic colonies. The formation of these various hematopoietic colonies from umbilical cord blood was at least equivalent to bone marrow, and in some instances over 5 times more effective. There appeared to be a statistically significant correlation between the numbers of colony-forming units (CFU-E) and the male infants. The weight of the infants also showed a statistically significant correlation with the burst forming units, erythroid (BFU-E) and the granulocytic-monocytic colony (CFU-GM). The BFU-E also appeared to be greater in number when the time between collection and plating was shorter. Author-abstract.

SO Br-Vet-J. 1989 May-Jun. 145(3). P 212-9.

JT BRITISH VETERINARY JOURNAL.

PT JOURNAL-ARTICLE (ART).

AB Following the deposition of radiocaesium from the *Chernobyl* accident the movement and slaughter of sheep in upland areas of west Cumbria, Scotland and Wales was restricted. Studies on the radioecology of Cs-137 and Cs-134 have been conducted at a farm within the affected area of west Cumbria since July 1986. The radiocaesium activity of upland sheep was found to decline when they were brought on to the farms' enclosed pastures and rise when they were returned to the open fell, where the radiocaesium content of vegetation has remained higher than on the pastures. The Cs-137 activity concentration of mixed grassland vegetation samples from the fell has declined over the study period, whereas the Cs-137 activity of ewes whilst grazing on the fell was higher in summer of 1987 than in autumn 1986. A number of factors which may have contributed to this discrepancy were investigated and are discussed. It is suggested that husbandry changes would be effective in reducing the number of lambs leaving the restricted area with radiocaesium activities over the limit (1000 Bq/kg fresh weight Cs-134 + Cs-137) set by the United Kingdom authorities. SO Br-Vet-J. 1989 May-Jun. 145(3). P 206-11.

JT BRITISH VETERINARY JOURNAL.

PT JOURNAL-ARTICLE (ART).

AB As a result of the *Chernobyl* accident sheep and cattle in Wales, Cumbria and Scotland became contaminated with radionuclides of caesium and iodine. In the worst case, the maximum levels of contamination were of the order of 4000 Bq/kg of caesium-137 and 2000 Bq/kg of caesium-134 in muscle and 2,000,000 Bq/kg of iodine-131 in the thyroid gland. Calculations show that the radiation dose rates to the animals from these burdens of the radionuclides of caesium would have been approximately one thousandth of the dose rate needed to cause clinical signs of damage; in the case of iodine-131 approximately 10,000 times higher levels of the nuclide would have been required to cause clinically perceptible damage to the thyroid gland. In any foreseeable nuclear accident severe problems of human health would arise before any detrimental effects on livestock could be detected. Author-abstract.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).

AB During the past decade worldwide experience concerning radiation accidents demonstrated that the medical diagnosis and therapy of radiation victims has to be reconsidered. This paper describes and analyzes the clinical relevance of one of the most simple diagnostic methods, namely daily monitoring of the characteristic blood cell changes. On the basis of these methods the physician is in the position to decide at an early stage-independently of the physical dose-whether reversible or irreversible damage of the hemopoiesis is present. This is of great importance because the expected clinical development and, thus, the therapy and prognosis are different. The different behaviour of the blood cells depends on their life span, cell kinetics, radiation sensitivity and pathophysiology. Reversible damage (category I-IV) can be recognized at the latest on the 5th-6th day after radiation exposure and, according to the degree, may require supportive therapy. Irreversible damage which can probably be repaired by stem cell transfusion (category V) can also be determined on the 5th to the 6th day after radiation exposure. Irreversible damage without any chance of survival (category VI) can already be diagnosed 24 hours after the radiation event. Reversible and irreversible damage to hemopoiesis with the typical blood cell changes is presented with reference to some patients exposed to ionizing radiation in the Marshall Islands 1954, in Oak Ridge 1958, in *Chernobyl* 1986, in Los Alamos II 1946 just as III 1958, and in Wood River Junction 1964. AB OBJECTIVE--To evaluate the outcome of pregnancy in Finnish women after the accident at the *Chernobyl* nuclear power plant on 26 April 1986. DESIGN--Geographic and temporal cohort study.

SETTING--Finland divided into three zones according to amount of radioactive fallout. SUBJECTS--All children who were exposed to radiation during their fetal development. Children born before any effects of the accident could be postulated--that is, between 1 January 1984 and 30 June 1986--served as controls.

INTERVENTIONS--Children were divided into three temporal groups: controls, children who were expected to be born in August to December 1986, and children who were expected to be born in February to December 1987. They were also divided, separately, into three groups according to the three geographic zones. END POINT--Incidence of congenital malformations, preterm births, and perinatal deaths.

MEASUREMENTS AND MAIN RESULTS--There were no significant differences in the incidence of malformations or perinatal deaths among the three temporal and three geographic groups. A significant increase in preterm births occurred among children who were exposed to radiation during the first trimester whose mothers lived in zones 2 and 3, where the external dose rate and estimated surface activity of caesium-137 were highest. CONCLUSIONS--The results suggest that the amount of radioactive fallout that Finnish people were exposed to after the accident at *Chernobyl* was not high enough to cause fetal damage in children born at term. The higher incidence of premature births among malformed children in the most heavily polluted areas, however, remains unexplained. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB Under neurological investigation were 113 patients with different degrees of severity of acute radiation disease (ARD). The patients were relatively evenly irradiated by beta- and gamma-rays as a result of CPP accident. The onset time and markedness of the signs of primary reaction were related to ARD severity. Early appearance of the signs of disturbances in the central nervous system functional state suggested a stronger affliction, malignant course and fatal outcome of the disease. In ARD patients with IV-th and III-rd degree of severity the syndromes observed were these: acute radiation encephalopathy immediately caused by the ionizing irradiation of the CNS, and a secondary radiation-toxic encephalopathy. The hemorrhagic lesioning of CNS and cerebral hemispheres were noted in terminal stages. In rehabilitation phases, neurasthenic and neurovascular syndromes appeared irrespective of the ARD severity. PT JOURNAL-ARTICLE (ART).

AB A follow-up of 115 patients with acute radiation disease resulting from external gamma-beta-radiation confirmed a high value of the previously proposed principles of predicting a degree of severity on the basis of the clinical manifestations of a primary reaction of disease and some syndromes using methods of hematological and cytogenetic analysis. Early isolation of patients with ARD of II-IV degree, selective intestinal decontamination, administration of antibiotics of a broad spectrum of action, antimycotic and antiviral drugs, and gamma-globulin can practically eliminate the risk of

development of fatal infectious complications in medullary and transient types of radiation disease. The efficient use of thrombomass transfusion completely prevents development of the thrombocytopenic hemorrhagic syndrome. Experience in bone marrow transplantation requires a review of therapeutic indications.

PT JOURNAL-ARTICLE (ART).
AB The time dependence of the specific activity of *Chernobyl-derived* ¹³⁴Cs, ¹³⁷Cs and ¹⁰⁶Ru was determined in vegetation and soil samples from an old spruce stand within a period of 600 days after the beginning of the radioactive fallout. The results show that 70% of the total activity of radiocesium and 60% of radioruthenium deposited in the spruce stand were retained initially in the canopy. They were removed from the needles and twigs as a result of weathering (rain, wind, litter fall) and transferred to the forest floor, but only rather slowly (half-lives in the canopy: radiocesium, 90 days for the period 0-130 days, 230 days for the period 130-600 days; radioruthenium, 95 days for the period 0-200 days). The transfer of radiocesium and ruthenium to the forest floor by litter-fall was small when compared with that of weathering by rain or wind (radiocesium 7%, radioruthenium 8%, with respect to the total activity deposited in the canopy). The total deposition of radiocesium and ruthenium in the spruce stand was higher by 20 and 24%, respectively, than that observed in nearby grassland. The deposition velocity of radiocesium in the spruce stand was estimated at 5.5 mm s⁻¹, higher by a factor of 10 than the figure for grassland. Similar values were found for radioruthenium.

PT JOURNAL-ARTICLE (ART).

AB About a week after the reactor accident in *Chernobyl,* a number of German citizens returned to the Federal Republic of Germany from different places of residence in the U.S.S.R. Chromosome analyses of these individuals show a surprisingly significant increase in dicentric chromosomes in comparison to the laboratory control. Acentrics are nearly twice as frequent as dicentrics. Centric rings are also in evidence. Chromatid breaks do not significantly differ from the control with the exception of 1 place of residence. The frequency of aberrations is too high to be induced by absorbed doses calculated physically or by modelling techniques. So far, no explanation is available for the discrepancy-a factor of about 100-between calculated absorbed doses and the measured biological effect. Author-abstract.

AB Findings in the Food and Drug Administration's Radionuclides in Foods
program are summarized for samples collected between October 1, 1982,
and September 30, 1986. All radionuclide findings for Total Diet and
reactor samples were either in Action Range I or low in Range II of
the surveillance and control recommendations given by the Federal
Radiation Council. The only long-range trend noted was a
continuation of the general decline in dietary intake of ^{90}Sr since
1961. Imported food samples were analyzed for contamination after
the *Chernobyl* nuclear accident. The findings for imported foods
indicate that the surveillance efforts successfully targeted
contaminated foods, and that contamination levels were below levels
of concern for all but one oregano and 3 cheese samples.

PT JOURNAL-ARTICLE (ART).

AB The incidence of neural tube defects was monitored among all live- and still-births delivered between June 1986 and July 1988. In all there were 19,115 total births. The incidence of neural tube defects (NTD) was 1.9 per 1000 among those whose conception time was prior to May 1986. However, in conceptions occurring in May, June and July 1986, the NTD rate increased to a level of 8.9 per 1000, subsequently gradually declining to previous levels within 9 months. This dramatic change in incidence, which parallels a previous finding from Turkey, suggests that this finding may be associated with the *Chernobyl* disaster of May 1986. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB About 20% of the Swedish land area was considerably contaminated by radionuclides released by the nuclear accident at *Chernobyl,* Ukraine, in April 1986. However, less than 10% of the arable land was contaminated. The heavy contamination was closely correlated with the amount of rain received during the first days of May 1986. Immediate restrictions on grazing limited the early uptake of contaminants in animal products. Changes in management of animals, especially sheep, goats, and reindeer in the contaminated areas have effectively reduced the transfer of radionuclides to human beings. One important factor was the possibility of obtaining uncontaminated feeds from unaffected parts of the country. The direct costs during the first 2 years after the accident were approximately +10 million for analyses and +90 million for compensation to farmers for condemned products (milk, mutton, and reindeer meat) and reimbursement for purchase of uncontaminated feeds from other parts of the country. PT JOURNAL-ARTICLE (ART).

AB After the *Chernobyl* nuclear accident on 26 April 1986 Europe experienced increased radioactive radiation by contamination of the atmospheric aerosol and the soil. Foods emanating radioactive radiation were ingested by the population to an increased extent via the food chain. This proportion of radioactive radiation accounted for about 80% of the total irradiation exposure and prompted us to examine mother's milk, amniotic fluid and placenta of newborn in respect of their concentrations of radionuclides I-131, Cs-134 and Cs-137. Due to the short half-life of I-131 an increased concentration of this substance was seen only during the first eight weeks after the nuclear accident. On the other hand, however, there was a clear increase in Cs-134 and Cs-137 from this time onward, the highest concentration of these two nuclides being measured only after one year after the accident. Despite the enhanced exposure to radioactivity of mother's milk and amniotic fluid, the guideline values laid down by Federal German legislation were not exceeded. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB The teratological impact of radiological contamination from the *Chernobyl* accident was evaluated in relation to central nervous system and eye defects in 18 regional registries in nine countries of Western Europe. Six classes of anomaly were analysed: neural tube defects, arhinencephaly, microcephaly and brain reduction, hydrocephaly, anophthalmos and microphthalmos, and congenital cataract. Conceptions up to 31 August 1986 were grouped into two exposure cohorts. In cohort A the sensitive period of fetal development to radiation fell wholly or partly between 1 May and 30 June 1986. Cohort B included all cases exposed during their sensitive period on or after 1 May 1986. Observed frequencies of the six classes of anomaly in the exposed cohorts were compared with expected frequencies calculated from baseline rates for the period 1980-1985. The only significant increase was neural tube defects in Odense, Denmark (four cases observed in cohort A where 0.9 were expected). The results of the study do not show a general increase in the frequency of malformations in the countries of Western Europe. The evidence presented indicates that, in the regions studied, termination of pregnancies or invasive prenatal diagnostic examinations were not justified for women exposed during pregnancy. PT JOURNAL-ARTICLE (ART).

AB The accident at the *Chernobyl* nuclear power plant in April 1986 caused very uneven deposition of radionuclides in Finland. The deposited radionuclides were found in relatively high concentrations in fuel peat and especially in peat ash because a thin surface layer of peat-production bogs was extracted as fuel peat soon after the fallout occurred. Concentrations of artificial radionuclides in fuel peat and peat ash were measured at six peat-fired power plants in Finland throughout the heating season 1986-87. Concentrations of 137Cs in composite peat samples varied between 30 and 3600 Bq kg-1 dry weight and in ash samples between 600 and 68,000 Bq kg-1. High

concentrations in peat ash caused some restrictions to the utilization of peat ash for various purposes. Author-abstract.

JT ACTA ONCOLOGICA.

PT JOURNAL-ARTICLE (ART).

AB The pathways of ¹³¹I, ¹³⁴Cs and ¹³⁷Cs from the *Chernobyl* fallout to man were followed in the county of Vasterbotten, Sweden. Reported airplane measurements had shown that the ground deposition of ¹³⁷Cs was 3-40 kBq/m² with hot spots with more than 80 kBq/m². Multiplying with a factor of 0.6 gave the ¹³⁴Cs deposition and an approximate factor of 20 the ¹³¹I ground deposition. The effective dose equivalent from ¹³¹I became low, less than 0.1 mSv, as the cows were stabled. The ¹³⁷Cs activity concentration in different types of food was measured in approximately 8,000 samples. The most important sources of Cs intake in man were lake fish, elk (European moose) and reindeer. Variations with time was studied in detail for four types of lake fish. Whole-body measurements on more than 250 persons showed that no group of people on average received more than 1 mSv from food during the first year after the *Chernobyl* accident. However, single persons eating large amounts of reindeer meat received up to 2.5 mSv. People buying all their food in ordinary provision-shops got less than 0.1 mSv from the food during the first year. The present level of ⁹⁰Sr activity concentration in man will only give an effective dose equivalent of 0.004 mSv/year, most of it being a result of the atmospheric nuclear bomb tests.

JT HEALTH PHYSICS.
PT JOURNAL-ARTICLE (ART).
AB This paper provides evidence that most of the Pu in the near surface air today is due to resuspension. Vertical and particle size

distribution in near surface air over a period of three years were measured. The seasonal variations of Pu in air and the influence of meteorological parameters on these variations are shown. Samples were taken before the *Chernobyl* accident in an area where only Pu fallout from the atmospheric nuclear tests of the early sixties occurs. The comparison of the behavior of Pu with other trace elements, which were also measured, showed similar behavior of Pu and elements like Ca, Ti and Fe in near surface air. This confirms that most Pu is resuspended because the main source for these elements in air is the soil surface. Resuspension factors and resuspension rate are estimated for all measured elements. A resuspension factor of $0.8 \times 10^{-8} \text{ m}^{-1}$ and a resuspension rate of $0.09 \times 10^{-9} \text{ s}^{-1}$ is calculated for Pu. Author-abstract.

JT HEALTH PHYSICS.
PT JOURNAL-ARTICLE (ART).
AB One hundred-two samples of colostrum milk, collected during spring of 1987, approximately one year after the reactor accident at *Chernobyl*, were measured for radiocesium contamination. The data showed a normal-type distribution with a mean contamination concentration of 16.4 Bq L^{-1} . A weak correlation of the data to the mothers' diet was established by taking into account four of the main staples in the area. The corresponding transfer coefficient was deduced with a value of $f_m = 0.06 \pm 0.03 \text{ d L}^{-1}$. The resultant effective dose received by breast-feeding infants was estimated, on the average, as $0.012 \text{ mrem d}^{-1}$. Author-abstract.

PT JOURNAL-ARTICLE (ART).
AB Radioactive material was deposited throughout the Northern Hemisphere as a result of the accident at the *Chernobyl* Nuclear Power Station on 26 April 1986. On the basis of a large amount of environmental data and new integrated dose assessment and risk models, the collective dose commitment to the approximately 3 billion inhabitants is calculated to be 930,000 person-gray, with 97% in the western Soviet Union and Europe. The best estimates for the lifetime expectation of fatal radiogenic cancer would increase the risk from 0 to 0.02% in Europe and 0 to 0.003% in the Northern Hemisphere. By means of an integration of the environmental data, it is estimated that approximately 100 petabecquerels of cesium-137 (1 PBq = 10¹⁵ Bq) were released during and subsequent to the accident.

AB Levels of ¹³⁷Cs and ¹³⁴Cs resulting from the *Chernobyl* nuclear
accident were studied in 195 birds that winter in two regions of
Spain. Only five of the 12 species examined were contaminated. The
average values for ¹³⁷Cs vary between 1.6 and 41 Bq kg⁻¹ fresh. In
particular, the contamination for song-thrushes (*Turdus philomelos*)
are compared between the regions of Extremadura and Valencia, 350 km
east of Extremadura at the same latitude. The results show that the
contamination of birds wintering in Spain decreases from east to
west. The whole-body dose commitment for humans consuming these
contaminated birds was calculated. The values are well below the
established ICRP guideline. Author-abstract.

TI Feeding green-cut forage contaminated by radioactive fallout to dairy
cows.
SO Health-Phys. 1988 Dec. 55(6). P 855-62.
JT HEALTH PHYSICS.
PT JOURNAL-ARTICLE (ART).
AB Grass contaminated by radioactive fallout from the *Chernobyl* accident
was cut with 150 mm (Treatment 1) and 50 mm (Treatment 2) stubble
height and fed to 20 dairy cows. The transfer of ¹³⁷Cs and ¹³¹I from
the greencut forage to milk was studied during a four-week and a
two-week period, respectively. The four-week period was followed by
a three-week period with nearly uncontaminated feeds. Cutting with
high stubble height significantly reduced the activity concentration
in forage compared with low stubble cutting, the average contents
kg⁻¹ dry matter being 385 Bq ¹³⁷Cs and 24 Bq ¹³¹I in Treatment 1
versus 6656 Bq ¹³⁷Cs and 249 Bq ¹³¹I in Treatment 2. Apparent
treatment effects were also demonstrated by the ¹³⁷Cs concentration
in milk, with maximum weekly means of 23 Bq kg⁻¹ (Treatment 1) and 92
Bq kg⁻¹ (Treatment 2). Single day maximum concentrations of ¹³¹I in
milk were 4 Bq kg⁻¹ (Treatment 1) and 9 Bq kg⁻¹ (Treatment 2). The
mean transfer coefficients (d kg⁻¹) were calculated to be 0.67×10^{-2}
and 0.19×10^{-2} for ¹³⁷Cs (weeks 2-4) and 1.8×10^{-2} and
 0.2×10^{-2} for ¹³¹I (week 2) in Treatments 1 and 2, respectively.
The lower value for ¹³⁷Cs might possibly be associated with an

enhanced ash content of the forage. Feeding nearly uncontaminated rations rapidly decreased the ¹³⁷Cs levels in milk in both treatments with calculated effective half-times over the three-week period of 10 and 7 d, respectively. Author-abstract.

AB After the accidents at *Chernobyl,* the Soviet Union, and in Goiania, Brazil, there is increasing concern about the medical risks from radiation accidents. This overview summarizes the principles of nuclear energy, the biologic effects of accidental radiation exposure, the emergency response to nuclear accidents, and approaches to treating radiation injuries. Also discussed are the related issues of reactor safety, the disposal of radioactive waste, and the proliferation of nuclear weapons. With the increasing use of radioactive materials for power, weapons, and medical diagnostics, the medical community needs to understand the health consequences of radiation exposure. PT JOURNAL-ARTICLE (ART).
AB After the April 1986 nuclear reactor accident at *Chernobyl* in the Union of Soviet Socialist Republics, samples of human placenta and breast milk were tested for 1 year to determine the levels of radioactivity. The radionuclide iodine 131 was never beyond the

detection limit of our gamma detector for both matrices. As to cesium isotopes 134 and 137, the highest levels detected in breast milk (6 Bq.L-1) and placenta (15.8 Bq.kg-1) were recorded in March 1987. Study data for breast milk and placenta are in agreement with the values calculated by means of double-compartment food-milk and food-placenta models. With regard to placental content, the cesium contribution to the average dose during the year after the *Chernobyl* accident was calculated to be 40 to 60 microSv. Author-abstract.

PT JOURNAL-ARTICLE (ART).

AB The reactor accident of *Chernobyl* in April 1986 has shown us all the dangers which are inherent even in the peaceful use of atomic energy. The effects of exposure to ionizing radiation are dependent on biological effectiveness, on dose, on duration of exposure and on the age of the exposed person (the younger the graver). Acute ionizing radiation of the whole body leads to radiation disease or radiation syndrome of different stages of severity according to dosage. If the patient survives other consequences of ionizing radiation may arise: non-stochastic effects such as cataracts, keloid formation, fibrosis of the lungs and infertility) and stochastic effects (oncogenesis and mutagenesis). The sensitivity to ionizing radiation is especially high in childhood because of the high velocity of cell metabolism and cell growth, the large body-surface area and because their repair mechanism following radiation damage is not yet. PT JOURNAL-ARTICLE (ART).

AB A three compartment (air-grass-milk) milk contamination model for 131I has been applied to atmospheric, grass and milk data, following the April 1986 nuclear accident at *Chernobyl*.* Samples of ovine and bovine milk collected daily by a large dairy company in Ioannina (northwestern Greece), throughout the month of May 1986 have been employed. The contamination impulse in the area, which provides the input to the model, has been approximated by a first order gamma-variate curve. Transfer rates and decay constants have been extracted by fitting predictions of the model independently to each

set of data (air, grass and milk). All model parameters obtained from more than one set of data show remarkable consistency. These parameters are used to calculate the transfer coefficients fm for the transport of radioiodine at equilibrium for sheep and cows. The results are also employed for the extraction of radiation dose estimates sustained through ingestion and inhalation by the population in the area. Author-abstract.

SO Health-Phys. 1988 Nov. 55(5). P 773-7.

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB Iodine-131 in milk and in rain water in Nagoya, Japan, (a location 8,000 km from *Chernobyl*) was monitored between May and July 1986. The ¹³¹I concentration in rain water ranged from 43.1 Bq L⁻¹ on 4 May to 15 mBq L⁻¹ on 12 July, and that in milk ranged from 21.8 Bq L⁻¹ on 19 May to 11 mBq L⁻¹ on 14 July. Iodine-131 concentrations in milk were estimated to be 4 to 6 times greater than those in rain water during the first few weeks after the accident. Both concentrations decreased with approximately the same effective half-life of 5.9 +/- 0.3 d for rain water and 5.0 +/- 0.2 d for milk. The ¹³¹I concentration in milk sold in markets varied from dairy to dairy and ranged from 0.07 to 0.2 times that in fresh milk. The maximum thyroidal dose equivalents estimated for an adult man and for a baby were far lower than the population annual dose equivalent to the thyroid from natural radiation. Author-abstract.

JT JOURNAL OF NUCLEAR MEDICINE.

PT JOURNAL-ARTICLE (ART).

AB The accident at the nuclear power plant of *Chernobyl* on April 26, 1986 led to radioactive contamination of many countries including Sweden. The population was exposed to released radionuclides, both by inhalation and from contaminated food. We have studied the content of gamma-emitting radioisotopes in the thyroid glands of a normal population from southern Sweden using measurements of samples taken at autopsy. The first samples are from a person who died on April 27, 1986. This report contains results for ¹³¹I and ¹³³I. The

time-activity curve for ^{131}I shows an immediate uptake with a maximum 18-26 days after the accident. No measurable levels were observed after 93 days. We have found that the increase in dose equivalent to the thyroid for the population of southern Sweden due to the released ^{131}I and ^{133}I will be less than 0.1 mSv. This may lead to an increase in the incidence of thyroid cancer of 0.1% during a period of 25 yr. Author-abstract.

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

AB Estimates of both individual and collective doses received by the United States population following the *Chernobyl* accident have been made by using the data obtained from the U.S. Environmental Protection Agency's Environmental Radiation Ambient Monitoring System. Radionuclides associated with the debris first were measured in precipitation and surface air particulates at Portland, OR and Olympia, WA on 5 May 1986. Iodine-131 was the most consistently measured nuclide in all media, although several Cs and Ru isotopes also were observed. Strontium and any actinides notably were absent from the samples at the lower level of detection. The highest calculated individual-organ dose due to intake during May and June 1986 was 0.52 mSv to the infant thyroid in the state of Washington. This was predominantly (98%) from the ingestion of milk. The maximum U.S. collective dose equivalent to any organ was calculated to be 3,300 person-Sv to the thyroid. Risk estimates project three excess lung cancer deaths and an additional four deaths due to cancers of thyroid, breast and leukemia in the U.S. population over the next 45 y from exposure during the May-June 1986 interval. The only long-lived radionuclide measured in milk samples following the accident was ^{137}Cs . We estimate 20 excess fatalities from the ingestion of ^{137}Cs in milk during all subsequent years, with six of these due to lung cancer and the majority of the remainder distributed approximately equally among cancers of the thyroid, breast, liver and leukemia. A total of 100 excess fatalities from all dietary components was estimated. Because of the uncertainty of risk estimates from data such as those available for this study, all calculated values carry a range of uncertainty from a minimum of one-half the calculated value to a maximum of two times the calculated value. The estimated excess fatalities given above may be compared with corresponding projected cancer mortality from all other causes: 41,000 fatalities from thyroid cancer and 3,800,000 fatalities from lung cancer are estimated to occur within the U.S.

population during the next 45 y. Author-abstract.

XFrom: marnie@ccwf.cc.utexas.edu

Subject: lunch friday

To: arminw@bcm.tmc.edu Well, beleive it or not, I just spoke with Dr. Gottlieb and she said lunch Friday will be just fine. I gave her your e-mail address and she said she'd get in touch with you and work it all out.

So, if you need me, too, one of you needs to let me know what you decide.

Also, I meant to thank you for all the diaspora and other stuff you gave me to help with my proposal- I couldn't have written it with out those papers. It was just the information I needed to put it all into perspective.

Thanks! and thanks for meeting with Dr. Gottlieb for me- I really do appreciate it.

One more thing-There was a health fair here last week, and I happened to go by a table for the school of public health in Houston.

I was wondering about a couple of things. First of all, what kind of jobs does a PHD in public health get you, what about an MD and a masters in public health, and- I know you have a PHD in anatomy (unless I am mistaken)- if I don't get accepted into med school, how would I get a job

like yours?All right- that's all for now.

more:

Bye!

-Marniemore:

AN 93141293. 93044.

AU Powell-E-C. Tanz-R-R.

IN Division of General Academic and Emergency Pediatrics, Children's
Memorial Hospital, Chicago, IL 60614.

TI Comparison of childhood burns associated with use of microwave ovens
and conventional stoves.

SO Pediatrics. 1993 Feb. 91(2). P 344-9.

JT PEDIATRICS.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB To identify the incidence, type, and severity of burns associated
with microwave oven (MW) use and to compare MW-associated burns with
those associated with use of conventional stoves, we conducted a
review of a national data base. Data were obtained from the US
Consumer Product Safety Commission Injury Information *Clearinghouse*
for 1986 through 1990 concerning burn injuries to children (0 to 19
years). There were an estimated 5160 burns associated with MW use.
The mean age was 7.6 years (median, 6 years); 25% of burns were to
children younger than 36 months old. Fifty-eight percent involved
females. Most MW burns were scalds (95%); 16% of these scalds were
from exploding eggs or other food. No MW burn involved a body
surface area greater than 25% and no patient required hospital
admission. Microwave oven burns were compared with stove burns.
There were an estimated 41198 stove-associated burns to children.
The mean age was 5.8 years; the median was 3 years. Forty-five
percent of burns were to children younger than 36 months old; 55%
were to males. Most stove burns (74%) were thermal; 7% involved a
body surface area greater than 25%. Five percent of children with
stove burns required hospital admission. We conclude that (1) burns
to children associated with MW use are less frequent and less severe
than stove burns; (2) MW burns predominantly affect females; and (3)
burn prevention efforts should emphasize the hazards of stoves, which
vastly exceed those of MWs. Author-abstract.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB OBJECTIVE--To assess the impact of diverse continuing medical
education (CME) interventions on physician performance and health
care outcomes. DATA SOURCES--Using continuing medical education and
related phrases, we performed regular searches of the indexed
literature (MEDLINE, Social Science Index, the National Technical
Information Service, and Educational Research Information
Clearinghouse) from 1975 through 1991. In addition, for these years,
we used manual searches, key informants, and requests to authors to
locate other indexed articles and the nonindexed literature of adult
and continuing professional education. STUDY SELECTION--From the
resulting database we selected studies that met the following
criteria: randomized controlled trials; educational programs,
activities, or other interventions; studies that included 50% or more
physicians; follow-up assessments of at least 75% of study subjects;
and objective assessments of either physician performance or health
care outcomes. DATA EXTRACTION--Studies were reviewed for data
related to physician specialty and setting. Continuing medical
education interventions were classified by their mode(s) of activity
as being predisposing, enabling, or facilitating. Using the
statistical tests supplied by the original investigators, physician
performance outcomes and patient outcomes were classified as
positive, negative, or inconclusive. DATA SYNTHESIS--We located 777
CME studies, of which 50 met all criteria. Thirty-two of these
analyzed physician performance; seven evaluated patient outcomes; 11
examined both measures. The majority of the 43 studies of physician
performance showed positive results in some important measures of
resource utilization, counseling strategies, and preventive medicine.
Of the 18 studies of health care outcomes, eight demonstrated
positive changes in patients' health care outcomes.
CONCLUSION--Broadly defined CME interventions using practice-enabling
or reinforcing strategies consistently improve physician performance
and, in some instances, health care outcomes. Author-abstract.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Data on conjoined twins have been collected from 14 different
malformation monitoring programs around the world. Among over 28
million births, 312 cases were identified. After considering
underascertainment in one large program, the best estimate of the
incidence based on the sum of induced abortions and births is 1.3 per
100,000 births. The distribution according to type of twinning, the
sex distribution (39% males) and the stillbirth rate (47%) are
presented. The presence of malformations not directly related to the
area of fusion is discussed. In three women, thyroid disease was
present and five women had been treated for infertility before
conception. Author-abstract.

TI The longevity of Growing Healthy: an analysis of the eight original sites implementing the School Health Curriculum Project.
 SO J-Sch-Health. 1992 Mar. 62(3). P 83-7.
 JT JOURNAL OF SCHOOL HEALTH.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB The status of the Growing Healthy curriculum (School Health Curriculum Project `SHCP:) was examined in the eight sites selected in 1969 by the National *Clearinghouse* on Smoking and Health to receive funded training and implementation support. A contact person from each site completed and returned a questionnaire pertaining to the district's continued implementation (institutionalization) of the SHCP. Most districts had not continued to implement the program. Reasons for discontinuation included loss of the "program champion" and insufficient administrative leadership. Districts continuing to implement the program generally were smaller in size, and employed a part-time coordinator for the SHCP. Recommendations for institutionalizing future instruction programs include identifying replacement program coordinators and other administrators to ensure continuity and support for the program over time, and conducting process and impact evaluations on program effects. Author-abstract.

 AU Robinson-J-C. Paxman-D-G.
 IN Center for Occupational and Environmental Health, School of Public Health, University of California, Berkeley 94720.
 TI The role of threshold limit values in U.S. air pollution policy.
 SO Am-J-Ind-Med. 1992. 21(3). P 383-96.
 JT AMERICAN JOURNAL OF INDUSTRIAL MEDICINE.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB This paper analyzes the role of threshold limit values (TLVs) in national air pollution policy during the 1980s, a period in which the Environmental Protection Agency (EPA) sought to delegate to individual states the authority to evaluate and regulate airborne toxic substances. We focus on 20 carcinogens and 11 substances with non-genotoxic health effects that were regulated by local air toxics programs using TLVs. Data from EPA's National Air Toxics Information *Clearinghouse* indicate that maximum TLV-based Ambient Air Level guidelines (AALs) frequently exceed minimum TLV-based AALs by a

factor of greater than 1,000. Cancer potency data from EPA's Integrated Risk Information System suggest significant risks remain at TLV-based AALs. Cancer risks at the median TLV-based AAL exceed 1,000 cases per million exposed persons for cadmium (1,040), nickel and its compounds (1,420), propylene oxide (1,550), coke oven emissions (1,860), benzene (2,500), arsenic and its compounds (7,300), N-nitrosodimethylamine (21,000), asbestos (21,500), and ethylene dibromide (55,000). We also summarize published studies that report non-genotoxic health effects in workers exposed at levels near the TLV for 11 substances whose AALs were based on TLVs. Contrary to the assumption frequently made by state air toxics program, TLVs cannot be taken to represent no observed effect levels (NOELs) for regulatory purposes. Author-abstract.

AN 92226028. 92000.
AU Curtis-S-E. Stricklin-W-R.
IN University of Illinois, Urbana 61801.
TI The importance of animal cognition in agricultural animal production systems: an overview.
SO J-Anim-Sci. 1991 Dec. 69(12). P 5001-7.
JT JOURNAL OF ANIMAL SCIENCE.
PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).
LG English (EN).
AB To describe and then fulfill agricultural animals' needs, we must learn more about their fundamental psychological and behavioral processes. How does this animal feel? Is that animal suffering? Will we ever be able to know these things? Scientists specializing in animal cognition say that there are numerous problems but that they can be overcome. Recognition by scientists of the notion of animal awareness has been increasing in recent years, because of the work of Griffin and others. Feeling, thinking, remembering, and imagining are cognitive processes that are factors in the economic

and humane production of agricultural animals. It has been observed that the animal welfare debate depends on two controversial questions: Do animals have subjective feelings? If they do, can we find indicators that reveal them? Here, indirect behavioral analysis approaches must be taken. Moreover, the linear additivity of several stressor effects on a variety of animal traits suggests that some single phenomenon is acting as a "clearinghouse" for many or all of the stresses acting on an animal at any given time, and this phenomenon might be psychological stress. Specific situations animals may encounter in agricultural production settings are discussed with respect to the animals' subjective feelings.

AB The National AIDS *Clearinghouse* is an information service provided by the Centers for Disease Control. The *Clearinghouse* was established in 1987 to respond to increasing numbers of public and professional inquiries, to disseminate accurate information, and to make referrals to local sources of information and assistance. Four data bases--Resources and Services Database containing information about more than 16,000 organizations that provide counseling and testing for human immunodeficiency virus (HIV) and acquired immunodeficiency syndrome (AIDS) and other education and prevention services; Educational Materials Database containing more than 8,000 individual, hard-to-find educational materials; Funding Database; and the AIDS Clinical Trial Information Service (ACTIS) Database--are searched by information specialists to respond to more than 45,000 requests annually for information from a variety of health professionals, organizations, and the general public. Between 1987 and 1991, the *Clearinghouse* disseminated more than 60 million copies of

publications related to HIV and AIDS. Information and education remain the most critical tools for the prevention of HIV infection, and the National AIDS *Clearinghouse* provides an essential element for the dissemination of education and prevention information.

TI National AIDS Hotline: HIV and AIDS information service through a
toll-free telephone system.

SO Public-Health-Rep. 1991 Nov-Dec. 106(6). P 628-34.

JT PUBLIC HEALTH REPORTS.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB The National AIDS Hotline (NAH), a service of the Centers for Disease Control (CDC), is an information resource for the population of the United States, its Territories, and Puerto Rico concerning the human immunodeficiency virus (HIV) and acquired immunodeficiency syndrome (AIDS). Since its inception in 1983, NAH has grown to be the world's largest health-related hotline service. NAH has received an average of more than 1.4 million calls per year since October 1987. Services of NAH include responding to the public's questions about HIV and AIDS and providing referrals to State and local resources. All services, including HIV and AIDS publications, are provided free of charge. The public contacts NAH 24 hours a day, 7 days a week, through a toll-free telephone system. Services are available to English-speaking, Spanish-speaking, and deaf populations. Each service has its own telephone number--English-speaking, 1-800-342-2437; Spanish-speaking, 1-800-344-7432; TTY service for the deaf, 1-800-243-7889. NAH employs approximately 170 information specialists to answer calls. The facility uses modern telecommunications technology to effectively manage and direct calls to 43 work stations. Each work station is supported by a personal computer that allows access to CDC's National AIDS *Clearinghouse* data bases for referrals and publication ordering. NAH ensures that

information provided to the public is current, accurate, and consistent with approved government policy. Quality assurance reviews address call management, delivery of information, and content of calls. Author-abstract.

LG English (EN).
AB Assessed the needs of mutual-help groups in relation to how self-help
clearinghouses can best assist. Most important problems centered on
member involvement, attendance and recruitment, lack of public
awareness, and finances. Most important needs were for greater
public education and more referrals to groups. Significant
differences were found across different types of organizational
affiliation for the problems of recruitment of members, lack of
public awareness, and problem members. The dynamic nature of
mutual-help groups may naturally produce many of the turnover,
attendance, and involvement problems which in turn generates the
ongoing need to recruit new members in part through greater public
awareness. Many of the goals and needs of mutual-help groups,
coupled with the large number of group members, may lead to
significant social and policy change in health and mental health
services. Author-abstract.

JT JOURNAL OF BURN CARE AND REHABILITATION.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB In this study we contacted all of the 149 major North American burn facilities that treat children. The survey determined topics covered in discharge teaching, personnel administering the programs, methods used, and obstacles encountered. The subjects addressed and the personnel involved have changed little from a decade ago. Unfortunately, one fourth of the centers still do not deal with emotional aspects of burns in their discharge programs. For program delivery, videotape is becoming an increasingly accepted teaching method. Eighty-five percent of burn facilities experienced barriers to patient education at discharge, with more than half reporting three or more difficulties. The most common difficulty was time constraints (50%), followed by language and sociocultural barriers (41%), lack of receptivity by clientele (39%), lack of educational materials and planning (26%), and inadequate funding (25%). Some of these problems might be alleviated by the establishment of a *clearinghouse* for burn educational materials. Author-abstract.

 AB The HIV education and prevention strategy of the Centers for Disease Control has three principal components: (a) public information and education, (b) education for school-aged populations, and (c) risk reduction education and individual counseling and testing services for people at increased risk of HIV infection. The most visible components of the public information and education programs are the National Public Information Campaign ("America Responds to AIDS"), the National AIDS Hotline system, and the National AIDS Information *Clearinghouse.* Components of the youth education program consist of funding for national health and education organizations, funding for State and local education departments, training, surveillance of education efforts, and evaluation. Counseling and testing has entailed performance of approximately 2,500,000 HIV antibody tests with pre- and post-test counseling, notification and counseling of sexual and needle-sharing partners of those infected with HIV, and targeted risk reduction education through community-based organizations. Over time, these activities will continue to evolve and become more effective. Author-abstract.

TI Risk assessment and risk management of noncriteria pollutants.
SO Toxicol-Ind-Health. 1990 Oct. 6(5). P 245-55.
JT TOXICOLOGY AND INDUSTRIAL HEALTH.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Noncriteria air pollutants are synonymous with hazardous air
pollutants (HAPs), air toxics or toxic air pollutants (TAPs). The
term noncriteria pollutants refers to all air pollutants except for
the criteria pollutants (SOx, PM, NOx, CO, O3, and Pb). Air toxics
are pervasive in our environment worldwide in varying degrees. Uses
of these chemicals are varied and numerous; their emissions are
ubiquitous, and they include organic compounds such as chlorinated
hydrocarbons, dioxins, aldehydes, polynuclear aromatic hydrocarbons,
and heavy metals such as chromium, nickel, cadmium, and mercury.
There are more than 70,000 chemicals that are in use commercially in
the United States, and we know relatively little about their ambient
concentrations, persistence, transport and transformation as well as
their effects on health and the environment, many of which take
decades to emerge. The United States Environmental Protection
Agency, under the authority of Section 112 of the Clean Air Act, is

mandated to regulate any air pollutant which, in the Administrator's judgment, "causes, or contributes to, air pollution which may reasonable be anticipated to result in an increase in serious irreversible or incapacitating reversible illness." For such regulatory decision-making, EPA's Office of Health and Environmental Assessment (OHEA) provides scientific assessment of health effects for potentially hazardous air pollutants. In accordance with risk assessment guidelines developed by OHEA over the years, Health Assessment Documents (HADs) containing risk assessment information were prepared and were subjected to critical review and careful revision to produce Final Draft HADs which serve as scientific databases for regulatory decision-making by the Office of Air Quality Planning and Standards (OAQPS) in its risk management process. EPA developed data-bases such as the Integrated Risk Information System (IRIS) and the National Air Toxics Information *Clearinghouse* (NATICH) and a technical assistance response system called the Air Risk Information support Center (AIR RISC), in addition, to help in implementation of the National Air Toxics Program by state and local regulators. AB The National Resident Matching Program is a centralized *clearinghouse* through which new medical graduates in the United States obtain their first positions. The history of this market, from the market failures that the centralized system was designed to address, to the present, is discussed, and a hypothesis about the behavior of such markets is presented. New evidence is then presented from a set of similar centralized markets in the United Kingdom. Because some of these latter markets have failed, while others have succeeded, they

provide a natural experiment that permits the hypothesis to be tested. The new evidence also suggests directions in which modifications of existing procedures might be considered.

TI Factors influencing the development and use of interactive video in nursing education. A Delphi study.
SO Comput-Nurs. 1990 Jul-Aug. 8(4). P 151-9.
JT COMPUTERS IN NURSING.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB The purpose of this study was to identify factors impeding development and use of interactive video (IAV) in nursing education in order to specify actions that would facilitate its development and use. Nurse educators with experience in development of IAV programs were defined as the experts, and a three-round Delphi study was conducted. Study findings revealed that participants were aware of obstacles to development and were able to suggest some ways to overcome them. Subjects clearly identified content they want in IAV programs, and were especially united on applications for simulations. They agreed on benefits of IAV for students, but were less certain about how it might affect faculty roles, and were undecided about measurable advantages of IAV. Conservative predictions were made about how evolving IAV technology might change the process of nurse education in the future. To promote IAV development and use the author recommends cooperative efforts between nurse educators and developers in the business sector and an educational thrust targeted for specific groups. Moving beyond existing nursing roles and institutional models, the author makes two major suggestions: establishment of a new nursing specialist, the nurse/instructional designer, and the creation of an information center staffed by these new specialists who will design and develop programs, provide education and consultation, maintain a *clearinghouse* for IAV programs, research, and technology, and take a leadership role in the integration of this powerful instructional delivery system into the entire health field. JT AMERICAN JOURNAL OF PHYSICAL MEDICINE AND REHABILITATION.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Of the 3.3 of every 1000 persons in the United States who use a wheelchair, an estimated 3.3% per year have a serious wheelchair-related accident. Yet, only isolated case reports of fatal accidents have appeared. To obtain a better estimate of the incidence and nature of fatal accidents, a search was carried out of the death certificate database (1973-1987) of the National Information *Clearinghouse* of the Consumer Product Safety Commission; 770 wheelchair-related deaths were identified. The majority, 596 persons (77.4%), experienced a fall from their chairs or tipped over. Of 85 deaths (11%) caused by environmental factors, stairs were implicated in 51 (60.0%). Of 48 fatal burns (6.2%), 27 (57.3%) were related to smoking. Asphyxia owing to restraints occurred in 44 persons (5.7%) of all ages and caused 10 of the 17 deaths (58.8%) among persons 1-20 yr old. Wheelchair-related accidental death is uncommon (about 0.2% of serious accidents per year), but some types of accidents appear to be preventable. Author-abstract.

AB Four hundred and fifty-nine fatal tapwater scald burn injuries
reported to the Injury Information *Clearinghouse* of the Consumer
Product Safety Commission from 1979 to 1986 were studied. Data
concerning the 459 deaths were abstracted from the death certificate
file maintained by the Clearing house. Risk estimates were derived,
using the resident population of the USA as of 1 July 1982 as the
midpoint population estimate. Over half the deaths occurred in those
over 75 years of age, while about one-fifth of the deaths occurred in
children younger than 5 years of age. The crude mortality rate was
approximately two deaths per million population over the 8-year
period studied. In all age groups, black-skinned people experienced
an approximate three-fold increase in risk (RR = 3.23, 95% CI: 2.87,
3.63). Among the elderly, males experienced an approximately 50 per
cent increase in risk (RR = 1.47, 95% CI: 1.26, 1.72). One of every
eight fatal injuries was sustained in a public building or
residential institution. Implications of the current findings in
terms of targetted prevention efforts are discussed.

JT JOURNAL OF THE AMERICAN ACADEMY OF DERMATOLOGY.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB In 1988, Dr. Thomas Jansen, then president of the American Academy of
Dermatology, established a Presidential Commission on Melanoma and
Non-Melanoma Skin Cancer, with Dr. Arthur Sober as commission
chairman. The Commission was directed to coordinate the Academy's
diverse public and professional educational and screening activities
related to skin cancer. Among the mandates of the Commission was the
organization of a *clearinghouse* of current educational materials on
skin cancer for health care providers and consumers. This
complication is considered to be especially significant now because
of increased effort by dermatologists to encourage physician visits
and routine patient self-examination for early detection of skin
cancer. The national and international campaigns to increase
awareness of the harmful effects of the sun have generated much
excellent educational information. Some audiovisual material,
notably slide sets, will be especially helpful to meet increasing
demand on dermatologists to present lectures to local consumer
groups. This listing should facilitate ordering of these materials.
Because of the lag time between preparation of this document and its
publication, cost and availability data may have changed. The

compilation will be updated periodically and printed in the Journal. The ongoing development of new educational materials requires continuous updating. It is hoped that readers who become aware of new relevant material will send this information to the author, in care of the Communications Division at the Academy offices in Evanston. International materials will be included in the next compilation. Author-abstract.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB The prevalence and time trends of spina bifida and anencephaly in the central area of Israel have been studied using data derived from four hospitals affiliated with the International *Clearinghouse* for Birth Defects Monitoring Systems. Spina bifida rates show a continuous increase from 1978 (1.1/10,000) to 1986 (7.4/10,000) with a peak in 1984 (7-fold increase compared with 1978). The logistic regression analysis of proportion of cases revealed a significant linear trend over time (P less than 0.005). Anencephaly rates increased from 1978 to 1981 but later decreased continuously until 1986 when the prevalence returned to the initial level of 1978. This time trend of spina bifida may represent a real alarm; the implications of this observation are discussed. Author-abstract.

AB Water and sanitation services and hygiene education are crucial in preventing communicable and other diseases which daily take an enormous toll both in morbidity and mortality around the world. Diarrheal diseases are the most prevalent, affecting hundreds of millions of infants, children, and others. There is a current major demographic trend of migration to and explosive growth of low-income peri-urban settlements in and around large cities in developing nations. These settlements lack adequate and affordable water supplies and often have no sanitary facilities whatsoever. They are perfectly suited for the flourishing of water- and sanitation-related communicable and other diseases, which add considerably to the misery of abject poverty. However, working with members of these communities to provide water and sanitation services can both prevent such diseases and improve economic conditions. International assistance must be facilitative rather than interventionist. Developed nations should greatly increase their financial contribution for the facilities necessary for better water and sanitation. Initially, it is important to create an international urban information center to act as a *clearinghouse* of information. It would also be helpful to begin a four-decade urban sanitation planning effort along with an "Urban Watch" to promote significant developments in peri-urban settlements. Author-abstract.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Multiskilled practitioners have been in health care settings for a long time. The form multiskilled practitioners have taken has varied with the cultural, socioeconomic, and technological constructs of the times. Some multiskilled practitioners have come and gone while others, such as the medical assistant and physician assistant, have remained. The complexity and sophistication of skills being combined have increased over time as have the degree level and opportunities for dual certification. Skills have been combined both across and within disciplines. There is currently a greater number and variety of formal programs to prepare multiskilled health practitioners in educational institutions and health care facilities, and more informal on-the-job training efforts than ever before--and they are increasing. Employment of multiskilled personnel has become a survival strategy for health care institutions in this current era of cost containment. Multiskilled allied health practitioners with basic nursing skills (ie, LPN level) may also provide one step toward a solution to the nursing personnel shortage being experienced by some health care facilities. The catchword for multiskilled has become not "whether," but "how."¹⁵ It is to everyone's benefit to learn from the efforts of those with experience in implementing the multiskilled health practitioner concept for both national and international application. The National Multiskilled Health Practitioner *Clearinghouse* intends, through its publications, services, and resource files, to serve as the cornerstone upon which the information from those with experience can be repositied and disseminated. JT MEDICAL CARE.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Research in progress at the National Center for Health Statistics for
evaluating the usefulness of composite measures of health status for
assessing the nation's health is described. Three measures suitable
for use in the general population, the Health Insurance
Experiment-Functional Limitations (HIE-FL), the Health Utility Index
(HUI), and the Quality of Well-being (QWB) scale, have been mapped to
data collected in the 1980 National Health Interview Survey (NHIS).
Analysis using current algorithms for making composite function
status measures according to the QWB methods suggests that
traditional single indicators of health tend to overestimate the
level of health by about 10%. When symptoms and problems are added
to the composite function score, the overestimate as measured by the
single indicator is at least 50%. The authors are continuing to
validate these algorithms, to develop similar ones for the HIE-FL and
HUI, and to extend the analysis to data collected in 1977, 1979, and
1984. Current results indicate that to realize fully the benefits of
composite measures, well-established, valid, and reliable measures of
health-related quality of life should be included as part of the
regular NHIS data collection procedures. Author-abstract.

LG French (FR).

AB The authors describe a population-based birth defects registry, started in 1976. The system surveys about 85,000 births per year, occurring in 140 maternity units and representing more than ten per cent of all the births in France. Monitoring first covered the Rhone-Alpes region, then was extended to the Auvergne region in 1983 and to the Jura district in 1985. The method of investigation was "multi-source", because any doctor in the zone covered was in a position to notify a malformation to the registry. (497 obstetricians, pediatricians, pediatric surgeons, fetopathologists, geneticists and cytogeneticists). Malformations were coded with a specific terminal elaborated in the registry (1,600 items). The mothers' exposures to drugs during the first trimester of pregnancy were coded by trade names. The registry is a full member of the International *Clearinghouse* for Birth Defects Monitoring Systems, an international organisation now including in this group 25 regional or national birth defects registries and covering more than 3 million births per year. The 1986 results of monitoring birth defects in the described registry are given as examples. Within the eleven years (1976-86), 15,000 cases of malformations were registered, and two clusters have been detected and followed-up: femoral aplasia/hypoplasia in 1980-81 and oesophageal atresia in 1984. No cause was found for these "epidemics". The strong association between in utero exposure to valproic acid with spina bifida is the main result of the activities of the registry since its creation. AB Because of the variety of needs engendered by AIDS, a broadbased response to the epidemic is warranted. The traditional medical model, with its emphasis on inpatient hospital care, is expensive and fails to address other needs of people with AIDS (PWAs). This paper outlines an alternative model: the community-based response, or continuum-of-care model. It builds on earlier community models of an integrated network of service providers who can better meet a range of needs of PWAs outside the hospital. Although the model may include a designated hospital AIDS unit that supplies inpatient services, the continuum-of-care model incorporates other nonacute and psychosocial services offered through community-based providers, and these services rely to a large extent on volunteers. Nationwide, more than 400 community-based AIDS service organizations have been formed in response to the growing AIDS epidemic, or have evolved from existing organizations. The National AIDS Network (NAN) was formed in 1985 by five such organizations to represent at the national level

the vision of community-based AIDS care. As the nexus for a national community-based response, NAN acts as a conduit for service providers to share experience as well as a *clearinghouse* for information and programs. Author-abstract.

JT PUBLIC HEALTH REPORTS.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB The human immunodeficiency virus (HIV) is estimated to have infected more than a million people in the United States and millions more in other countries. Even though there is no vaccine or effective treatment, HIV infection can be prevented through behavioral change. As the lead Public Health Service Agency for disease prevention, the Centers for Disease Control (CDC) has designed and implemented information and education activities with the ultimate goal of preventing HIV infection and AIDS in the United States. The target populations include the general public, school- and college-aged populations, persons infected or at increased risk of infection, minorities, and health workers. Because AIDS will be with us for a long time, CDC views educating the public as a long-term undertaking. The agency has initiated an intensive continuing national public information campaign, an informational brochure to be distributed to every U.S. household, a national AIDS information toll-free hotline, and a *clearinghouse* system that will maintain a comprehensive inventory of AIDS information resources and services. CDC also supports public information and education efforts by State and local health agencies. To reach school- and college-age youth, CDC, in consultation with governmental and national private sector organizations, developed guidelines for effective school health education to assist school health personnel in determining the scope and content of AIDS education. CDC also works with State and local

education agencies to help carry out and evaluate educational efforts to prevent the spread of HIV among school- and college-age youth.(ABSTRACT TRUNCATED AT 250 WORDS). Author-abstract.

TI Epidemiology of bladder exstrophy and epispadias: a communication from the International *Clearinghouse* for Birth Defects Monitoring Systems.
SO Teratology. 1987 Oct. 36(2). P 221-7.
JT TERATOLOGY.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB A study of infants with bladder exstrophy or epispadias was based on data from ten malformation monitoring systems around the world. The material is derived from nearly 6.3 million births. The recorded prevalence at birth of bladder exstrophy was 3.3 per 100,000 births and of epispadias (without bladder exstrophy) 2.4 per 100,000. The recorded rates of bladder exstrophy did not vary between the monitoring systems, but the rates of epispadias did. Furthermore, nearly all registered infants with epispadias were males. The sex ratio for bladder exstrophy was 1.5:1. Perinatal deaths occurred mainly when other malformations were also present. There was an increased risk in this group of malformations in infants of women aged less than 20 years. At high parity (3+), an increased risk was observed for bladder exstrophy, but there was a decreased risk for epispadias. The birth weight distribution was shifted slightly more to the left in isolated bladder exstrophy than in isolated epispadias, but was considerably shifted to the left when other malformations existed with bladder exstrophy. Most infants with other malformations belonged to the cloacal exstrophy sequence. There was no definite time trend between 1970 and 1985 in the prevalence at birth of bladder exstrophy. The study demonstrates how data from different monitoring registries can be pooled to characterize a rare malformation. Author-abstract.

AB Many *clearinghouses* have been organized within the last decade to
promote mutual aid and to provide referral information about
self-help groups to potential members. Few of the assumptions that
underpin the operation of these programs have been evaluated,
however. This paper presents an evaluation of the Self-Help
Information Service, a *clearinghouse* integrated with a generic
information and referral service. The results were generally
positive with respect to operator and consumer satisfaction,
community responsiveness, and the system's capacity to undertake
numerous service and research functions. They also pointed up
several changes that might be made to improve the system's impact.
It is concluded that a new practice specialty might be developed
within a *clearinghouse* context, and that the *clearinghouse* concept
might serve as one cornerstone of a funding policy that supports the
self-help approach. Author-abstract.

AB OBJECTIVE--To assess the efficiency of an early pregnancy assessment unit in the *care* of women with bleeding or pain in early pregnancy. DESIGN--Analysis of women attending in the first year of the unit's

operation and in the six months immediately before its introduction.
SETTING--Early pregnancy assessment unit in a district general hospital serving a population of 310,000. PATIENTS--1141 women referred with bleeding or pain in early pregnancy. MAIN OUTCOME MEASURES--Length of stay in hospital required for diagnosis and treatment. RESULTS--Before the unit was established the mean admission time was one and a half (range half to three) days for women who required no treatment and three (one and a half to five) days in women requiring evacuation of uterus. These times were reduced to two hours as an outpatient and one day respectively for most women after the unit was established. Between 318 and 505 women were estimated to have been saved from unnecessary admission, and 233 had their stay reduced; the associated saving was between pounds 95,000 and pounds 120,000 in one year. CONCLUSIONS--The early pregnancy assessment unit improved the quality of *care* and also produced considerable savings in financial and staff resources.

TI *Cost* effectiveness of antenatal hepatitis B screening and vaccination
of infants.

SO Aust-N-Z-J-Obstet-Gynaecol. 1990 Nov. 30(4). P 331-5.

JT AUSTRALIAN AND NEW ZEALAND JOURNAL OF OBSTETRICS AND GYNAECOLOGY.

PT JOURNAL ARTICLE (ART).

LG English (EN).

AB Over a 2-year study period 5,858 public antenatal patients were
screened with the Welcome hepatitis B surface antigen HA screening
kit; 52 (0.89%) were positive (carriers) and 45 (87%) of these were
identifiable as high risk patients and would have been diagnosed by
selective screening; the remaining 7 (13%) would have been missed.
Using a subsample of 1,000 women, it was found that high risk factors
were present in 237 (23.7%). Restriction of screening to the high
risk group *cost* an estimated \$97 per carrier identified; universal
screening *cost* \$354 to identify each carrier. Screening only the
high risk group would have missed the 7 carriers in the low risk
group, which was estimated to number 4,470 patients (76.3% of the
total). Estimated *cost* of screening the low risk group was \$14,036,
or \$2,005 per carrier identified. The advent of highly effective
vaccines enables the almost complete prevention of vertical
transmission of hepatitis B. In mid-1988, vaccine *costs* in terms of
hepatitis B prevention per baby were estimated to be \$2,432 for
vaccination of babies born to mothers in the high risk group,
irrespective of maternal serology; and \$9,729 for universal
vaccination. Carrier rates vary between populations. For our clinic
patients, universal screening and vaccination of all babies of high
risk group mothers are considered appropriate. Selective screening
may be more appropriate in a low risk private practice.

 TI A *cost-benefit/cost-effectiveness* analysis of smoking cessation for
 pregnant women.
 SO Am-J-Prev-Med. 1990 Sep-Oct. 6(5). P 282-9.
 JT AMERICAN JOURNAL OF PREVENTIVE MEDICINE.
 PT JOURNAL ARTICLE (ART).
 LG English (EN).
 AB Research has shown that pregnant women who smoke cigarettes increase
 their risk of having low birthweight (LBW) infants. Recent
 randomized trials indicate that women who quit smoking early in
 pregnancy reduce their risk of delivering a LBW infant. Using
 various sources, we estimated the *cost-effectiveness* of a smoking
 cessation program for preventing LBW and perinatal mortality.
 Assuming the program would *cost* \$30 a participant and that 15% of the
 participants would quit smoking, we determined that a program offered
 to all pregnant smokers would shift 5,876 LBW infants to normal
 birthweight and would *cost* about \$4,000 for each LBW infant
 prevented. Since infants born to smokers are at 20% greater risk for
 a perinatal death, a smoking cessation program could prevent 338
 deaths at a *cost* of \$69,542 for each perinatal death averted.
 Compared with the *costs* of caring for these LBW infants in a neonatal
 intensive *care* unit (NICU), smoking cessation programs would save
 \$77,807,054, or \$3.31 per \$1 spent. The ratio of savings to *costs*
 increases to more than six to one when we include reducing long-term
 care for infants with disabilities secondary to LBW in the *benefits*
 from smoking cessation programs. These findings argue for routinely
 including smoking cessation programs in *prenatal* *care* for smokers.

TI Screening and surveillance of pregnancy hypertension--an economic
approach to the use of daycare.

SO Baillieres-Clin-Obstet-Gynaecol. 1990 Mar. 4(1). P 89-107.

JT BAILLIERES CLINICAL OBSTETRICS AND GYNAECOLOGY.

LG English (EN).

AB Frequent measurement of blood pressure is an accepted part of routine
outpatient antenatal *care.* Women found to have mild hypertension may
be further monitored for signs of progressive disease, while women
with proteinuria or severe hypertension may be admitted for more
intensive surveillance or treatment. In practice, the course and
ultimate severity of this disorder are unpredictable and women with
mild hypertension are frequently admitted. Recently, daycare has
grown as an option for assessing women with hypertension as it offers
the advantage of more extensive evaluation than is possible at an
outpatient clinic and is widely assumed to be more *cost-effective*
than conventional management. However, its use in obstetrics has not
been subject to a formal economic appraisal. Such an evaluation is
currently being carried out in two hospitals in Scotland, one of
which uses daycare and inpatient admissions in the management of
hypertension and one of which uses domiciliary midwife visits as well
as hospital beds. Preliminary results suggest that the pregnancy
outcome in terms of birthweight, gestation at delivery, admission to
a special unit, etc., are the same in the two units for women with
mild hypertension (diastolic 90-99 mmHg, no proteinuria). The *costs*
per patient were less in the hospital with a daycare unit. These
lower individual *costs,* however, do not mean that the overall *costs*
to the health service are less in a hospital with daycare. This will
depend on the average number of visits to daycare for women with mild
hypertension, the proportion of hypertensive women receiving daycare,
whether freed inpatient beds are closed or redeployed, and the
capital *costs* of establishing a day unit. Data has also been
collected on women's *costs* and views which will ultimately be
presented and should play a part in any decision to implement or
continue daycare. Author-abstract.

 TI Pregnancy and medical *cost* outcomes of a self-help *prenatal* smoking
 cessation program in a HMO.
 SO Public-Health-Rep. 1990 Jul-Aug. 105(4). P 340-7.
 JT PUBLIC HEALTH REPORTS.
 LG English (EN).
 AB The results of a randomized clinical trial of a *prenatal* self-help
 smoking cessation program are reported in terms of the pregnancy and
 cost outcomes. The study population were the socioeconomically and
 ethnically diverse members of a large health maintenance organization
 (HMO) who reported that they were smoking at the time of their first
 prenatal visit. The intervention consisted predominantly of printed
 materials received through the mail. Compared with the usual *care*
 control group, women assigned to the self-help program were more
 likely to achieve cessation for the majority of their pregnancy (22.2
 percent versus 8.6 percent), gave birth to infants weighing on
 average 57 grams more, and were 45 percent less likely to deliver a
 low birth weight infant. An economic evaluation of the self-help
 program was conducted from the perspective of the sponsoring HMO.
 Based upon the expenditures associated with the neonates' initial
 hospital episode, the intervention had a *benefit-cost* ratio of 2.8:1.
 These findings provide strong evidence to support widespread
 incorporation of smoking cessation interventions as a standard
 component of *prenatal* *care.* Author-abstract.

TI Potential value of immunoperoxidase technique in assessment of genital herpes.
SO J-Fla-Med-Assoc. 1990 May. 77(5). P 516-9.
JT JOURNAL OF THE FLORIDA MEDICAL ASSOCIATION.
LG English (EN).
AB Cervicovaginal smears from 86 patients with suspicious genital herpes were screened by routine Papanicolaou stain. The slides were then destained and restained by a commercial immunoperoxidase kit for the detection of herpes simplex virus. Results were compared with

standard viral cultures performed on the same lesions. A statistically significant difference (P less than 0.05) was observed between the results of Papanicolaou-stained cytology and the immunoperoxidase technique. This study suggests that the immunoperoxidase technique is a rapid and reliable method of confirming a suspected diagnosis of herpetic infection. It is particularly useful in those patients without *prenatal* *care* who present in early labor when a rapid diagnostic test is required. Author-abstract.

PT REVIEW (REV). REVIEW, TUTORIAL (TUT).
LG Hungarian (HU).
AB The authors, following a short review of the currently available diagnostic and therapy methods of threatening premature delivery, introduce their own method. The most important feature of this method is a two-level, computerized telecommunicative system. According to the risk factors, physical examination and the patient's complaints (clinical parameters) a risk score analysis is made by the central computer of the outpatient clinic. Those pregnant women who fall into the high-risk group are followed-up by means of a portable contraction monitor. The treatment is introduced according to the registered spontaneous contraction activity. (hospitalisation, beta-mimetic etc.). After institution of the therapy the patient can be emitted to her home under the *care* of the portable monitor. Data of the registered and stored contraction activity from the patient's home can be transmitted to the central computer of the out-patient clinic via phone. If the telephone connection is not possible, the physician can read out the stored data from the memory of the portable monitor on its own display during regular visits. Finally

the authors make preliminary *cost-benefit* calculation on the basis of the literature and their own data and conclude that their method can be very *cost* effective as well. Author-abstract. 43 Refs.

TI Perinatal Health Belief Scales. A *cost-effective* technique for predicting *prenatal* appointment keeping rates among pregnant teenagers.

SO *J-Adolesc-Health-Care.* 1990 Mar. 11(2). P 119-24.

JT JOURNAL OF ADOLESCENT HEALTH *CARE.*

LG English (EN).

AB This study was designed to test two different methods for predicting pregnant teenagers at risk for failing to keep appointments for comprehensive *prenatal* *care.* Sixty-three pregnant adolescents completed psychological questionnaires assessing depression, social support, and life events. They and their primary health *care* provider also completed the Perinatal Health Belief Scales (PHBS) measuring the respondent's perception of risk and need for services. Following their infant's birth, adolescents completed a measure of health *care* satisfaction. Chart reviews provided data regarding birth weight, gestational age, Apgar scores, and appointment-keeping information. The results suggest that adolescents who failed to keep the most appointments were likely to have significantly lower levels of concern regarding their risks during pregnancy than their primary health *care* provider. Adolescents were more likely to keep appointments if they expressed levels of concern on the PHBS that were similar to their health *care* provider. The psychological measures and PHBS when applied individually, were not successful in predicting those with the greatest likelihood for nonadherence to appointments. Author-abstract.

TI *`Cost-effectiveness* analysis of HIV screening in pregnant women in
hospitals in the Paris region:.

TT Analyse cout-efficacite du depistage du VIH chez les femmes enceintes
dans les hopitaux de la region parisienne.

SO J-Gynecol-Obstet-Biol-Reprod (Paris). 1990. 19(1). P 36-42.

JT JOURNAL DE GYNECOLOGIE, OBSTETRIQUE ET BIOLOGIE DE LA REPRODUCTION.

LG French (FR).

AB Spontaneous diffusion of HIV screening at the occasion of pregnancy
has been especially rapid in France. In April-May 1988, 45% of
general practitioners systematically prescribed HIV screening during
premarital or *prenatal* consultations. Experimentation of systematic
prenatal HIV screening has been performed for some time in various
French maternity hospitals. On the basis of real data concerning HIV
screening of more than 15,000 pregnant women between August 1987 and
July 1988 in 9 Paris hospitals, a *cost-effectiveness* analysis has
been performed. It showed that the total *cost* of systematic
screening for women admitted to maternity hospitals for *prenatal* *care*
and whose HIV status was previously unknown, was about 1.5 million
French francs (about \$240,000) and that 22 new cases of HIV positive
were discovered. During the first five months (first period), the
mean *cost* per pregnant woman found to be HIV positive was about 42 to
45,000 FF (\$6,700-7,150). A similar calculation over the following
months, gave a mean *cost* 4 times higher. The *cost* and effectiveness
of a selective screening for high risk women were also estimated. In
this hypothetical case, 13.6% of women would have been tested, the
mean *cost* of discovering, at the hospital, a new HIV positive
pregnant woman would have been 7,500 FF (\$1,200) during the first
period. The quadrupling of the mean *cost* of identifying an HIV
positive pregnant woman by systematic hospital screening, despite a
concomitant increase in prevalence in the population, can be
explained only by an increase in *prenatal* screening prescribed by the
private practitioner in ambulatory medicine before the first hospital
prenatal visit. The monthly evolution of the proportion of women

already screened before consultation in one of the nine maternity hospitals had increased by almost 50% between the beginning and the end of the studied period. An evaluation of a policy of HIV screening during pregnancy depends, at least in the French health *care* system, on the different ways the ambulatory and hospital sectors complement themselves. Author-abstract.

TI The *cost* effectiveness of *prenatal* *care* in reducing low birth weight in New Hampshire.

SO Health-Serv-Res. 1989 Dec. 24(5). P 583-98.

JT HEALTH SERVICES RESEARCH.

LG English (EN).

AB This study calculates the *cost* effectiveness of adequate *prenatal* *care* in reducing the low birth weight rate for each of three socioeconomic groups of women: those with less than 12 years of education, those with 12 years, and those with more than 12 years. Target low birth weight rates for each group were those actually achieved by New Hampshire women receiving adequate *prenatal* *care* within respective education groups. The estimated total *cost* associated with low birth weight births among the 1981-1984 cohort of New Hampshire resident births was more than \$38 million. With universal adequate *prenatal* *care,* the low birth weight *costs* would be less than \$32 million, a *cost* savings of \$6.5 million. Since the additional *cost* of providing adequate *prenatal* *care* to all women was estimated to be \$2.5 million, the net *cost* savings were estimated to be \$4 million, or \$1 million per year. For each additional \$1 spent on *prenatal* *care,* \$2.57 in medical *care* *costs* would be saved. Author-abstract.

TI Universal *prenatal* hepatitis B testing: is it *cost-effective?*

SO Obstet-Gynecol. 1989 Nov. 74(5). P 808-14.

JT OBSTETRICS AND GYNECOLOGY.

PT REVIEW (REV). REVIEW, TUTORIAL (TUT).

LG English (EN).

AB It was recently recommended that all pregnant women undergo *prenatal* hepatitis B screening. This change from previous policy (which advocated screening of only those individuals with recognized epidemiologic risk factors) is a very costly strategy to use in an effort to prevent the perinatal spread of hepatitis B in the "no-risk-factor" population. Inherent problems already exist in screening, related to the following: 1) the failure for disease transmission to occur in the majority of hepatitis B e antigen-negative pregnancies, 2) the lack of established efficacy of prophylaxis in the hepatitis B e antigen-negative pregnancy, 3) the preponderance of hepatitis B e antigen negativity in pregnant hepatitis B surface antigen carriers, and 4) the compliance of the mother to ensure that the prophylaxis program is accomplished. These are further magnified by the lower rates of hepatitis B surface antigen and hepatitis B e antigen positivity in the population without risk factors. The major expense of a screening program is the hepatitis B surface antigen testing of the mother. The *cost* to prevent a clinically important case of hepatitis B in the neonates of mothers with no risk factors is \$180,000, which is 15 times the *cost* of preventing a case in neonates of mothers with risk factors. This price appears not to be *cost-effective.* Author-abstract. 47 Refs.

pregnant women.
SO *Med-Care.* 1989 Feb. 27(2). P 95-102.
JT MEDICAL *CARE*.
LG English (EN).

AB This article documents the process of an outreach program for locating disadvantaged women who, as a group, do not receive *prenatal* *care* early and have adverse pregnancy outcomes. Three full-time community residents searched for pregnant women for a year, being paid a commission for each woman that they found who enrolled for antenatal *care.* Outreach workers spent more than half of their time in the field, contacted 20 to 25 people per day, and used a variety of strategies to locate women. Fifty-two women entered the Harlem Hospital Medical Center health *care* system through the outreach process, with 104 pregnant women not already receiving antenatal *care* being identified by the outreach workers. Their effort, conversion rate, and yield were comparable to private sector salespeople. The *cost* per enrollee was high (although not higher than the *cost* of additional low-birthweight births). Alternatives for locating pregnant women are suggested. Author-abstract.

TI *Cost* effectiveness of ambulatory uterine activity monitoring.

SO Int-J-Gynaecol-Obstet. 1989 Feb. 28(2). P 127-32.

JT INTERNATIONAL JOURNAL OF GYNAECOLOGY AND OBSTETRICS.

LG English (EN).

AB A *cost* analysis is presented comparing 34 patients who received uterine activity monitoring versus 33 patients who attempted to detect uterine activity by palpation. All patients were at high risk for preterm delivery and were given the same educational information and *prenatal* *care* regarding signs and symptoms of preterm labor. The results revealed an increase in newborn days (640) and *cost* to those patients who were in the self-palpation group (\$13,364) compared to monitored parturients (268 days and \$8,633). The difference was attributed to neonatal morbidity from an increased number of preterm deliveries greater than 26 weeks but less than 37 weeks ($P = 0.04$).

The increase in NICU days was significant ($P = 0.03$). No difference in normal newborn *costs* for infants delivered after greater than 33 weeks could be detected between the two groups, but morbidity was increased among control infants delivering between 34 and 36 weeks. Uterine activity monitoring to prevent preterm birth appears to be medically effective and reduces *cost.* Author-abstract.

TI Maternal screening in prevention of neonatal infections: current
status and rationale for group B streptococcal screening.
SO J-Hosp-Infect. 1988 Feb. 11 Suppl A. P 328-33.
JT JOURNAL OF HOSPITAL INFECTION.
LG English (EN).
AB Maternal screening--either selective or universal--is an accepted
component of a number of strategies for prevention of congenital and
perinatal infections. Using the results of maternal screening at
prenatal visits and the presence of perinatal risk factors during
labour, neonatal group B streptococcal (GBS) early-onset disease can
be prevented by selective intrapartum chemoprophylaxis. Possible
variations on this strategy may employ semiquantitative tests for GBS
colonization at *prenatal* visits or, possibly, rapid bacterial
diagnosis intrapartum. Based on the incidence and economic impact of
GBS disease, selective intrapartum chemoprophylaxis appears
cost-effective in United States populations, but may not be so in
countries with lower incidence rates. Author-abstract.

TI A *cost-effectiveness* analysis of strategies to reduce infant mortality.
SO *Med-Care.* 1988 Apr. 26(4). P 348-60.
JT MEDICAL *CARE.*
LG English (EN).
AB This study compares the *cost* effectiveness of various health inputs and government programs in reducing race-specific neonatal mortality or death in the first 27 days of life. Approximately two thirds of all infant deaths occur within this period. The programs and inputs at issue are teenage family planning use; the supplemental food program for women, infants, and children (WIC); use of community health centers and maternal and infant *care* projects; abortion; *prenatal* *care*; and neonatal intensive *care.* Using an economic model of the family as the analytic framework, effectiveness is determined by using ordinary least squares and two-stage least squares to estimate infant health production functions across large counties in the United States in 1977. Estimates of *costs* are from a number of published sources. We find the early initiation of *prenatal* *care* to be the most *cost-effective* means of reducing the neonatal mortality rate for blacks and whites. Moreover, blacks *benefit* more per dollar of input use than whites. Neonatal intensive *care,* although the most effective means of reducing neonatal mortality rates, is one of the least *cost-effective* strategies. Author-abstract.

 TI A *cost-effectiveness* analysis of self-help smoking cessation methods for pregnant women.
 SO Public-Health-Rep. 1988 Jan-Feb. 103(1). P 83-8.
 JT PUBLIC HEALTH REPORTS.
 LG English (EN).
 AB Estimates of the *cost* effectiveness and *cost* *benefit* of health promotion-health education methods for pregnant smokers designed to increase birth weight are not available. This paper presents the results of a *cost-effectiveness* analysis from a recently completed randomized trial to evaluate the effectiveness of self-help smoking cessation methods for pregnant women in public health maternity clinics. The study population--309 pregnant smokers from 3 *prenatal* clinics--were randomly assigned, during their first clinic visit, to 1 of 3 groups: (a) group 1 received the standard clinic information and advice to quit smoking, (b) group 2 received the standard clinic information and advice to quit plus the manual "Freedom From Smoking in 20 Days" by the American Lung Association, and (c) group 3 received the standard clinic information and advice to quit plus the pregnancy-specific manual "A Pregnant Woman's Self-Help Guide to Quit Smoking." The quit rates by the end of pregnancy were 2 percent for group 1, 6 percent for group 2, and 14 percent for group 3. Analyses also indicated that the method used for group 3 was the most *cost* effective: group 3 achieved smoking cessation at less than half the *cost* experienced by the other two groups. Although additional studies are needed concerning the behavioral impact, *cost* effectiveness, and *cost* *benefit* of self-help health education methods for smoking cessation, the methods tested in this trial are promising as solutions to part of the problem of low birth weight among infants of smoking mothers in the United States. TI *Prenatal* nutrition services: a *cost* analysis.
 SO J-Am-Diet-Assoc. 1987 Feb. 87(2). P 204-8.
 JT JOURNAL OF THE AMERICAN DIETETIC ASSOCIATION.
 LG English (EN).
 AB The scarcity of information about program *costs* in relation to quality *care* prompted a *cost* analysis of *prenatal* nutrition services in two urban settings. This study examined *prenatal* nutrition services in terms of total *costs,* per client *costs,* per visit *costs,* and *cost* per successful outcome. Standard *cost-accounting* principles were used. Outcome measures, based on written quality assurance criteria, were audited using standard procedures. In the studied programs, nutrition services were delivered for a per client *cost* of \$72 in a health department setting and \$121 in a hospital-based *prenatal* *care* program. Further analysis illustrates that total and per client *costs* can be misleading and that *costs* related to successful outcomes are much higher. The three levels of *cost* analysis reported provide baseline data for quantifying the *costs* of providing *prenatal* nutrition services to healthy pregnant women. *Cost* information from these *cost* analysis procedures can be used to guide adjustments in service delivery to assure successful outcomes of nutrition *care.* Accurate *cost* and outcome data are necessary prerequisites to *cost-effectiveness* and *cost-benefit* studies.

 TI Public *benefits* and *costs* of government funding for abortion.
 SO Fam-Plann-Perspect. 1986 May-Jun. 18(3). P 111-8.
 JT FAMILY PLANNING PERSPECTIVES.
 LG English (EN).
 AB In state referenda to end public funding of abortions for poor women, one of the most successful tactics of abortion foes has been to charge that abortion funding increases the burden on taxpayers. A state-by-state analysis by The Alan Guttmacher Institute (AGI) shows that the opposite is the case. For every tax dollar spent to pay for abortions for poor women, about four dollars is saved in public medical and welfare expenditures. The savings are in public

expenditures that otherwise would have to be incurred because of the babies that poor women would have borne. On the basis of earlier research, it was assumed that 20 percent of Medicaid-eligible women who could not obtain abortions would give birth. Public *costs* examined in the AGI analysis include Medicaid expenditures for *prenatal* *care,* delivery and postnatal *care* for the mother, and for newborn *care,* neonatal intensive *care* and pediatric *care* for the child for the first two years of life; as well as expenditures for Aid to Families with Dependent Children (AFDC), food stamps and the Special Supplemental Food Program for Women, Infants and Children (WIC) during those first two years. The *benefit-to-cost* ratio varies from about 9:1 in Massachusetts to 2:1 in Hawaii and Pennsylvania. The net savings for the nation as a whole over a two-year period if abortions were publicly funded in every state would total at least \$339.6 million. Author-abstract.

TI *Prenatal* participation in WIC related to Medicaid *costs* for Missouri
newborns: 1982 update.
SO Public-Health-Rep. 1986 Nov-Dec. 101(6). P 607-15.
JT PUBLIC HEALTH REPORTS.
LG English (EN).
AB This study replicates a 1980 evaluation of WIC *prenatal* participation
in Missouri by using a file of 9,086 Missouri Medicaid records
matched with the corresponding birth records. This file was divided
into a WIC group containing 3,261 records and a non-WIC group of
5,825 records. The 1982 results generally confirm the 1980 results,
with the 1982 findings showing slightly improved pregnancy outcomes
for WIC participants and slightly reduced *benefit-to-cost* ratios
compared with the 1980 findings. In 1982, WIC participation was
found to be associated with an increase in mean birth weight of 31
grams and reductions in low birth weight rates (statistically
significant) and in neonatal death rates (not statistically
significant). The reduction in each rate was 23 percent. WIC
participation was also associated with a reduction in Medicaid *costs*
for newborns reported within 45 days of birth amounting to \$76 per
participant. For every dollar spent on WIC, about 49 cents in
Medicaid *costs* were apparently saved. However, wide 95 percent
confidence intervals (\$.07, \$.90) make it difficult to determine
precisely what impact WIC has on Federal and State budget outlays.

JT CURRENT OPINION IN RADIOLOGY.
PT JOURNAL ARTICLE (ART). REVIEW (REV). REVIEW, TUTORIAL (TUT).
LG English (EN).
AB Mammography, *breast* physical examination, and *breast* self-examination are recommended for *breast* *cancer* *screening.* Although in randomized trials of *screening,* mammography demonstrated a reduction in *breast* *cancer* mortality for women over 50, such data are not available for *breast* physical or self-examination. The Canadian National *Breast* *Screening* Study should provide data regarding the efficacy of *breast* physical examination alone. The World Health Organization has established trials to evaluate self-examination in the USSR and Germany. There is still controversy regarding routine mammographic *screening* and the optimal *screening* interval for women under age 50. The *costs* of mammographic *screening* remain a concern, but these *costs* can be lessened considerably through efficiency of mammographic services and a reduction in the number of false-positive interpretations that prompt biopsy. Primary care physicians can help to reduce *breast* *cancer* mortality by referring their patients for *screening* mammography and by performing *breast* physical examinations. Author-abstract. 30 Refs.

JT OBSTETRICS AND GYNECOLOGY CLINICS OF NORTH AMERICA.
PT JOURNAL ARTICLE (ART). REVIEW (REV). REVIEW LITERATURE (RLT).
LG English (EN).
AB Recognizing the enormous impact that quality *breast* *screening*

mammography can have on reducing *breast* *cancer* deaths, we need to determine when women's and physician's perceived restrictions for mammography examination impede the progress of its use for early *cancer* detection. A uniform system should emphasize valid communication and education between women and their physicians. Women seek to have a voice in their medical treatment. Yet that responsibility has an emotional price. Physicians and patients must decide together on the most appropriate strategies to enhance communication and adopt specific guidelines they will adhere to, to detect and cure early *breast* *cancer.* Women must be educated about *breast* *screening* mammography, and physicians must increase their efforts to proclaim its importance. Women need be assured the trend is toward using the most modern mammographic techniques. Quality medical care is medicine's purpose and in women's best interest. At present, no other diagnostic method is equivalent to mammography and capable of providing an equivalent impact on improving the detection and cure rate of *breast* *cancer.* Despite medical activities designed to reduce uncertainty in medicine, scientific evidence has not provided systematic answers as to the "best" way to approach issues of quality, *cost,* accessibility, or communication for *breast* *screening* mammography. No particular expert opinion or preference prevails for *breast* *screening* protocols. What is needed is adoption of a multidisciplinary approach, educating and motivating women and physicians to participate in *breast* *screening* activities. With trends directed toward high-volume *breast* *screening* operations, *low-cost,* quality mammography must be available and be impeccably performed. Some activities are natural subjects for financial quantification. It is objectionable to assume, however, that we can accurately place and agree on dollar amounts alone to represent the *costs* and *benefits* of *screening* mammography. The gaps between practices and attitudes about the *benefits,* risks, and *costs* of *screening* mammography suggest that people are not satisfied with the way physicians, women, influential groups, or regulatory agencies are balancing all of the elements. Better communication must exist between physicians and their peer groups involved in performing responsible mammography. Better communication must be achieved between physicians and women to take advantage of the usefulness of quality *breast* *screening* mammography. High-quality *screening* programs must be linked to third-party reimbursement and to legislation, if we are to make a difference. *Screening* mammography deserves our medical, economic, social, and political attention and action. Author-abstract. 32 Refs.

TI *Cost-effectiveness* analysis of mass *screening* for *breast* *cancer* in
Japan.
SO *Cancer.* 1991 Apr 15. 67(8). P 2021-9.
JT *CANCER.*
PT JOURNAL ARTICLE (ART).
LG English (EN).
AB The official Japanese recommendation for *breast* *cancer* *screening* is
physical examination by a physician, in contrast to US
recommendations of mammography. In this analysis of *breast* *cancer*
screening, the authors used Japanese data in a *cost-effectiveness*
model to compare the following five strategies: (1) no *screening* (N);
(2) physical examination alone (PE); (3) mammography (MG); (4) PE
followed by MG if PE findings were abnormal (PE---MG); and (5) PE
combined with MG for all screened women (PE + MG). None of these
programs would save medical expenditures. The total discounted net
costs per patient (in US dollars) were as follows: N, +54; PE, +412;
MG, +517; PE---MG, +340; and PE + MG, +731. The number of years of
life saved per cohort of 100,000 asymptomatic Japanese women would
range from 708 (PE---MG) to 3724 (PG + MG). The additional *cost* of
each strategy (compared with N) per additional year of life would be
+49,700 for PE, +40,400 for PE---MG, +14,300 for MG, and +18,000 for
PE + MG. The least costly *screening* option (PE---MG) does not have
the lowest *cost* per additional year of life saved (MG does). MG
would be preferable to the current Japanese recommendation of PE
alone. Author-abstract.

 TI Response by women aged 65-79 to invitation for *screening* for *breast* *cancer* by mammography: a pilot study.
 SO BMJ. 1990 Dec 8. 301(6764). P 1314-6.
 JT BMJ.
 PT JOURNAL ARTICLE (ART).
 LG English (EN).
 AB OBJECTIVE--To determine whether there is sufficient *benefit* to be gained by offering *screening* for *breast* *cancer* with mammography to women aged 65-79, who are not normally invited for *screening.* DESIGN--Pilot study of women eligible for *screening* but not for personal invitation. The results of this study were compared with the results of routinely screened younger women (aged 50-64) from the same general practice. SETTING--One group general practice in south Manchester. PATIENTS--The 631 women aged 65-79 on the practice list.

A total of 42 (7%) were excluded by the general practitioner, and 22 (4%) invitation letters were returned by the post office. MAIN OUTCOME MEASURES--Response rates to invitation for *screening* assessed by three indices: crude population coverage ratio, crude invited population coverage ratio, and corrected invited population coverage ratio. RESULTS--344 Patients aged 65-79 (61% of those invited, excluding those who could not be traced) were screened compared with 77% of women aged 50-64. The three response indices were higher for younger women than older: crude population coverage ratio = 66.5%, crude invited population coverage ratio = 69.3%, corrected invited population coverage ratio = 76.8% for women aged 50-64, compared with 54.5%, 58.4%, and 60.7% respectively for women aged 65-79. All four biopsies done in the older women gave positive results, giving a *cancer* detection rate of 11.6/1000 compared with 4.1/1000 among younger women. CONCLUSIONS--These results show that there is a potential for high attendance at routine *screening* by older women if they are invited in the same way as younger women. If these results are found elsewhere the *costs* and *benefits* of *screening* older women should be reassessed. Author-abstract.

JT SOCIAL SCIENCE AND MEDICINE.
LG English (EN).
AB The results of a *cost-effectiveness* analysis of cervical *cancer*
screening in The Netherlands are reported, emphasizing the analysis
of the *costs* of *screening* and consequent diagnosis and treatment.
Many organized *screening* policies are evaluated, differing in
age-range and interval between screens. The *cost* estimates are based
on organization charts, file studies and tariffs. The *costs* of
screening itself are by far the most important *cost* component.
Screening increases the *costs* of diagnosis. *Costs* for primary
treatment only rise for large *screening* policies. *Screening* causes
savings in *costs* of terminal treatment, but these are small compared
with the *costs* of *screening*.* The *costs* per life-year gained for the
most efficient policies amount to DFL 24,000 for the policy with 7
invitations per woman in a lifetime and rise considerably in case of
more than 10 invitations. Cervical *cancer* *screening* appears to be
less *cost-effective* than *breast* *cancer* *screening,* but compared with
other services the results are comparatively good. Implementing one
of the efficient organized *screening* policies and discouraging

spontaneous *screening* beyond that schedule leads to considerable savings. Moreover, many organized policies which are not efficient are still superior to spontaneous *screening.* Author-abstract.

AB The present paper analyses the epidemiologic effects of mass *breast* *cancer* *screening.* Mass mammography may possibly achieve a *breast* *cancer* mortality reduction in relative risk terms. However, this does not necessarily represent a net *benefit.* It is argued that the *benefits* and adverse effects of a *screening* programme must be measured in terms of absolute risks. According to this measure, the mortality reduction achieved by a mass *breast* *screening* programme is only one death per approx. 15,000 women-years. Many thousands of mammograms are needed to prevent one *cancer* death, and for each woman who can derive a direct *benefit* in terms of a prevented *breast* *cancer* death, hundreds of women have to suffer the anxiety of a positive *screening* mammography. Moreover, it is possible that adverse effects of *breast* *cancer* *screening* may contribute to mortality from other causes. Even with the assumption that *screening* can save lives, the net health effect of mass *breast* *cancer* *screening* is questionable and appears to be rather detrimental. It may be an error to recommend mass *breast* *screening.* Author-abstract. 47 Refs.

AB A *cost-benefit* analysis of the Swedish model for *screening* for neoplasma malignum mammae revealed scientific shortcomings in the basis for decision. It was not possible to determine whether the *screening* model involved a net loss or a net profit for the individual woman. Since false confidence seems to increase the mortality in *breast* *cancer* a new dimension was introduced, a sensitivity index as an expression of revealed fractions of the incidence in the participant population. This sensitivity index estimated some two thirds of the malignant neoplasms which are normally diagnosed in a two year period. Author-abstract.

AB The Swedish two county trial of *breast* *cancer* *screening* is now in its

tenth year. This paper presents detailed results on mortality from *breast* *cancer* and from all other causes, and on the population denominators at risk for each of the first 8 years of follow up, for each county separately. These data represent a two year update on the last major report. Results show an increasingly significant deficit in deaths from *breast* *cancer* among the 77,092 women invited to *screening* relative to the 56,000 not invited (RR = 0.68, p = 0.002), with no significant difference between the effects of *screening* in the two counties (p = 0.5). These results remain the same when adjusted for age. Analysis of all cause deaths shows no significant effect of *screening* (p = 0.5), nor was there any significant effect of *screening* on deaths from all causes other than *breast* *cancer* (p = 0.9). The rates of deaths from intercurrent illness in *breast* *cancer* cases were almost identical in the group invited to *screening* and the group not invited (p = 0.7). This result remained the same when adjusted for age. We calculate that in the age group 50-69 at entry, one *breast* *cancer* death was prevented per 4000 woman/years, per 1460 mammographic examinations, per 13.5 biopsies, and per 7.4 *breast* *cancers* detected. PT CLINICAL TRIAL (CTR). REVIEW (REV). REVIEW, TUTORIAL (TUT).

LG English (EN).

AB There is very good evidence that *screening* for *breast* *cancer* reduces mortality in women older than 50 years and suggestive but inconsistent evidence that *screening* is effective in reducing long-term mortality in women younger than 50 years. The probability that an average-risk woman will be diagnosed with *breast* *cancer* in the coming 10 years is about 130 in 10,000 for a 40-year-old woman,

230 in 10,000 for a 55-year-old woman, and 280 in 10,000 for a 65-year-old woman. The chance of dying from *breast* *cancer* diagnosed in the coming 10 years is about 90 in 10,000, 123 in 10,000, and 120 in 10,000 for women age 40, 55, and 65, respectively. Mathematical models based on data from controlled trials of *screening* programs indicate that *screening* annually for 10 years with *breast* physical examination will decrease the probability of death from *breast* *cancer* by about 25 in 10,000 for women in the three age groups and increase life expectancy by about 20 days. Adding annual mammography will decrease the probability of death from *breast* *cancer* an additional 25 in 10,000 and increase life expectancy an additional 20 days. The actual reductions in mortality observed in controlled trials are slightly lower. If women are screened annually for 10 years with *breast* physical examination and mammography, the chance for a false-positive result over the 10-year period is approximately 2500 in 10,000. On the population level, if 25% of women age 40 to 75 are screened annually with both examinations, deaths from *breast* *cancer* would be decreased by about 4000 in the year 2000. Net annual *costs* would be approximately \$1.3 billion. Recommending a *screening* strategy requires weighing the *benefits* against the risks and *costs.* Author-abstract. 30 Refs.

- AB The *costs* and effects of different invitation schedules of *breast*
 cancer *screening* are compared. The effect estimates are based on
 trials from the USA, Sweden and the Netherlands. The *cost* estimates

use registration data, file studies and organization charts. The calculations were performed with the MISCAN computer simulation package, which is developed especially for the evaluation of mass *screening* programmes. *Screening* women of 50-70 years at 2-yearly intervals is a relatively *cost-effective* schedule. In a real population, it will reduce *breast* *cancer* mortality by 12%. *Screening* of women under 50 is probably far less *cost-effective.* *Screening* induces a considerable shift towards *breast-conserving* therapy. Although a 12% mortality reduction may seem low, in absolute numbers this represents more than the total mortality from, e.g., cervical *cancer.* Moreover, *cost* per death prevented or per life-year saved is much lower than for most other medical interventions for which *cost-effectiveness* ratios are known, *screening* for cervical *cancer* included.  LG English (EN).
 AB In general, mass *screening* for health is of doubtful value, but specific programmes like *breast* *cancer* *screening* could be beneficial. *Breast* *cancer* is the major cause of death in middle-aged women in many countries. Experience in Sweden shows that properly designed and performed mammography *screening* can reduce mortality by one-third, and lead to a better quality of life for treated *cancer* patients. However, if radiation causes damage proportional to the dose even at low doses, these *benefits* could be offset by radiogenic *cancers* in younger age groups (particularly under 40 yr of age). In Sweden, the direct *cost* of *screening* equals about 15 pounds sterling. Swedish authorities consider well designed *screening* justified. Optimization is necessary and involves design, technique, staff competence and organization. An optimized program should save one life in 100 in the screened cohort, while perhaps one life in 10,000 might be lost due to radiogenic *cancers* (with conventional radiation risk assumptions).  JT JAMA.
 LG English (EN).
 AB Two quantitative methods, Confidence Profiles and CAN*TROL, are used to analyze evidence and estimate the health and economic consequences of adding annual mammography to annual *breast* physical examinations in asymptomatic women aged 40 to 49 years who are at average risk for *breast* *cancer.* Such women have about a 128 in 10,000 chance of having *breast* *cancer* in the next ten years and about an 82 in 10,000 chance of dying of such a *cancer.* Adding annual mammograms to annual *breast* physical examinations each year during that age decade would reduce the probability of death to about 60 in 10,000, a reduction of

about 26%. *Screening* would increase the expected lifetime of a woman destined to get *breast* *cancer* between ages 40 and 49 years by about 3.5 years. Ten years of *screening* with mammography in that age decade carries a risk of radiation-induced *cancer* of about one in 25,000 and a risk of a surgery recommendation for a lesion that is not *cancer* of about one in ten. If 25% of the women in this age group in the United States were screened every year, *breast* *cancer* mortality in the year 2000 would be decreased by about 373 deaths. In 1984 dollars, the *cost* of *screening,* workups, and continuing care in the year 2000 would be about \$408 million. Treatment *costs* would be decreased by about \$6 million, leaving a net increase in *costs* in the year 2000 of approximately \$402 million (1984 dollars).

 AB A *cost-benefit* analysis clearly shows that the *costs* for *screening* a large population of asymptomatic women are well within the *cost-benefit* range that is accepted for other areas within the medical care system. If profit and loss were the only considerations, one would opt for *screening* with combined examination for all women age 40 and older. If medical and philosophical considerations were to be included in the equation, clinical examination alone at any age cannot be justified. However, one might be able to justify mammography *screening.* Bierman has stated, "ultimately, when the scent is of flesh rather than figures, even the economist concedes that it will be important to insulate the individual practitioner (from *cost-benefit/cost-effectiveness* analysis) on a day-to-day basis because of potential conflict with the commitment to do what is best for each patient. Here is the crux. The economist's reference to the 'nation's health' is at best ambiguous and more likely meaningless. The physician's commitment to

the patient's health is neither of these: it is clear, undeniable, and profoundly meaningful." Reduction in *cancer* deaths is not easy to come by. When a method is available that can achieve this result, every effort should be made to make it available until it can be replaced satisfactorily by a less expensive, equally effective modality. Author-abstract.

AB The logistics of complying with current American *Cancer* Society *breast* *cancer* *screening* recommendations in a large health maintenance organization, serving more than 50,000 women age 40 or older, are described. An alternative *screening* approach estimated to be at least as health-effective as the American *Cancer* Society recommendations has been developed and appears to solve the problem and is financially feasible. *Cost-effectiveness* depends on optimal use of mammography and health-care personnel resources. The authors show how the start-up and maintenance *costs* of an organized program can be offset by future *cost* savings resulting from reduced long-term disability in patients diagnosed at Stages 0-1 as opposed to Stages 2 and later. Careful selection of the delivery model before implementation can make a *breast* *cancer* *screening* program *cost-effective* as well as health-effective. Author-abstract.

JT JOURNAL OF GENERAL INTERNAL MEDICINE.
PT JOURNAL ARTICLE (ART).
LG English (EN).
AB The U.S. Preventive Services Task Force recommendations *for*

screening *for* *hypertension* and high blood cholesterol are generally consistent with preexisting national guidelines promulgated by the Joint National Committee *for* Detection, Evaluation, and Treatment of High Blood Pressure and the National Cholesterol Education Program Expert Panel on Detection, Evaluation, and Treatment of High Cholesterol in Adults. While a welcome addition to the armamentarium of the clinician, the Task Force recommendations represent only a partial solution to our current epidemic of blood-pressure- and cholesterol-related cardiovascular disease. A meaningful reduction in society's burden of cardiovascular disease can be achieved only by complementing the Task Force recommendations with community-based mass treatment strategies aimed at shifting the distribution of blood pressure and cholesterol toward a biologically more normal pattern. Author-abstract.

AB PURPOSE: To review the evidence on four questions about *screening* asymptomatic adults *for* arterial *hypertension:* Is *hypertension* a significant health problem? Is it detectable at an early, presymptomatic stage? Is treatment available and effective? Do the benefits of *screening* outweigh the costs and risks? DATA IDENTIFICATION AND SELECTION: We did a computerized search of the MEDLARS data base to identify community-based trials of drug therapy *for* mild *hypertension;* other relevant citations are included when appropriate. DATA SYNTHESIS: We approached the preliminary questions in our analysis by narrative review and argument. The estimates of therapeutic efficacy are based on previously published meta-analyses.

The cost-effectiveness of *screening* was addressed by formal mathematical modeling of the effect of *screening* on various U.S. populations. RESULTS OF ANALYSIS: *Hypertension* is clearly a significant health problem. It can be detected early, and effective treatment is available. *Screening* asymptomatic adults *for* *hypertension* has benefits that compare favorably to the risks and costs involved. According to our estimates, *screening* is most cost-effective *for* older adults compared with younger adults and *for* men compared with women and is highly sensitive to the cost of therapy *for* mild *hypertension.* CONCLUSIONS: We recommend *hypertension* *screening* *for* all adults. We also discuss the frequency and setting of *screening* activities. When a low-cost therapy is used, the cost-effectiveness of *screening* *for* *hypertension* compares favorably with other cardiovascular interventions. Author-abstract.

LG English (EN).
AB In 1983/84, the Munich Blood Pressure Program (MBP) performed worksite *screenings* *for* arterial *hypertension* at 18 Munich companies. A participation of 51% (n = 7310) was achieved. After duplicate measurements of casual blood pressure 1084 participants were suspected of having actual *hypertension.* All suspected cases were invited *for* a reexamination to reduce the number of false-positive

hypertensives. Individuals with persisting *hypertension* after this *two-step-screening* were predominantly male, on the average younger than 50 years and showed a low level of antihypertensive drug treatment. About 75% of all detected hypertensives saw a family physician subsequent to the *screenings* *for* further management. Referrals and patient compliance were frequently reinforced by a computer based reminder system. A follow-up examination was performed among the MBP participants after two years. It showed that in 417 confirmed hypertensives of the primary *screenings* a marked increase in the proportion of treated and controlled hypertensives had occurred. This was true *for* younger and older hypertensives. Author-abstract.

TI Sequels to *screening* *for* *hypertension* and diabetes mellitus in Fiji.

SO Diabetes-Res-Clin-Pract. 1987 Nov. 4(1). P 15-22.

JT DIABETES RESEARCH AND CLINICAL PRACTICE.

LG English (EN).

AB We evaluated the outcome of a case-finding programme resulting from an epidemiological survey on diabetes and cardiovascular risk factors by re-interviewing 318 persons who had been found to have *hypertension* and/or diabetes mellitus in a population survey carried out in Fiji 1.5 years earlier in 1980. At re-examination, 34% of the hypertensive patients and 43% of the diabetic patients were not aware of their diagnosis. However, the proportion of treated hypertensive people was tripled and that of diabetic patients doubled. It was not possible to identify the characteristics of the persons who were missed in the follow-up. Many persons who were unaware of their condition regularly used, however, the existing health services available. On the other hand, several initially treated cases had no proper follow-up. More careful planning and development of comprehensive community-based programmes *for* *hypertension* and diabetes are needed in Fiji. Simple population *screening* *for* *hypertension* and diabetes may result in an extra work load and limit the available health care resources so that the overall outcome is not satisfactory. Author-abstract.

 SO Prev-Med. 1985 Jul. 14(4). P 519-31.
 JT PREVENTIVE MEDICINE.
 LG English (EN).
 AB The Munich Blood Pressure Program (MBP) is a community *hypertension* control program *for* the metropolitan area of Munich. It tries to improve "incidental *screening*" in doctors' offices in the city through continuing education programs *for* physicians and auxiliary personnel and, in addition, emphasizes worksite *screening* to bring high-risk hard-to-reach groups under treatment and control. Blood pressure (BP) is measured at the worksite under standardized conditions. Those with values greater than or equal to 140 mm Hg systolic BP and/or greater than or equal to 90 mm Hg diastolic BP at the first visit have BPs measured again within 1-5 days. If their BP values are still elevated, they are referred to their family

physicians *for* further assessment. At the same time, they are given a postage-paid card on which their doctors are asked to note the BP value measured in their offices. This postcard is returned to the MBP *for* evaluation. A computer-based reminder system informs all MBP participants at certain time intervals to have their BP checked. The text of the letters and the time interval between them depend on the most recent BP and treatment status data available to the MBP. In 1983, *screenings* were performed in seven firms. Participation rates of up to 57% were achieved *for* this entirely voluntary examination (3,948 participants). Age- and sex-specific prevalence rates *(for* the pooled data of the seven firms) were similar to those of a random sample of the Munich population (Munich Blood Pressure Study I). Seventy-four percent of those with elevated BP at first visit participated in the remeasurement at a second visit. Only 58% of these showed elevated BP values the second time. More than half (n = 101) of those second-visit hypertensives (greater than or equal to 160/95 mm Hg; n = 183) returned at least one completed postcard. The examining physician confirmed the hypertensive BP values in 60 of those cases. Of the 101, 57 were under treatment, 19 controlled and 38 uncontrolled. The follow-up period considered here lasted until May 1984 and varied from 5 to 15 months according to the date of *screening* in the respective firm. Only the first returned card has been evaluated thus far. Author-abstract.

PT REVIEW (REV). REVIEW, TUTORIAL (TUT).

LG Hungarian (HU).

AB Oral glucose tolerance testing (oGTT) was performed according to WHO criteria among obese pregnant women (body mass index greater than 28) who were recruited with the help of computerized pregnancy

counselling data base. oGTT was carried out *for* the first time between gestational ages of 16-20 weeks, and it was repeated monthly as far as possible. Gestational *diabetes* was diagnosed in 4 cases out of 50 obese patients. Two gestational diabetic patients needed insulin treatment. According to computerized data obese patients have significantly higher risk of having macrosomic infants and/or intrauterine death. Fasting blood glucose values of obese pregnant women were significantly higher in all the gestational ages. It is emphasized that obesity means a risk factor *for* gestational *diabetes,* but the onset of carbohydrate intolerance may be prevented or diagnosed as early as possible with the help of repeated oGTT during pregnancy and dietary counselling. In this way fetal complications, especially macrosomia will not develop. Author-abstract. 21 Refs.

JT ARCHIVES OF PATHOLOGY AND LABORATORY MEDICINE.

LG English (EN).

AB We examined the patient records of 6445 patient visits to an executive health surveillance program to evaluate the diagnostic yield from *screening* *for* *diabetes* mellitus by measurement of fasting serum glucose and hemoglobin A1c. We found increased fasting serum glucose levels (greater than or equal to 6.6 mmol/L) in 3% (197/6445), of whom only half received further confirmatory testing. Increased *screening* values *for* glucose were associated with a 70% incidence of *diabetes* mellitus and impaired glucose tolerance when subsequent oral glucose tolerance tests were performed. Confirmatory testing with the oral glucose tolerance test was equivalent in cost and superior in diagnostic yield to repeated fasting glucose determination. Nonetheless, preferential use by clinicians of repeated glucose determination was found to contribute to underdiagnosis. Hemoglobin A1c could not reliably predict impaired or diabetic glucose tolerance. We conclude that maximal value of

screening *for* *diabetes* mellitus is achieved only by obligatory confirmatory oral glucose tolerance testing. Author-abstract.

 TI The relative value of glycated albumin, hemoglobin A1c and fructosamine when *screening* *for* *diabetes* mellitus.
 SO *Diabetes-Res-Clin-Pract.* 1989 Nov 6. 7(4). P 243-50.
 JT *DIABETES* RESEARCH AND CLINICAL PRACTICE.
 LG English (EN).
 AB We compared the usefulness of three glycated serum proteins, glycated albumin (GA), glycated hemoglobin (HbA1c) and fructosamine (FA), *for* diabetic *screening* purposes. We measured these indices in 302 adults, most of whom underwent yearly physical examinations. We measured GA and HbA1c with high precision using high-performance liquid chromatography (interassay coefficients of variation 4.9 and 4.0%, respectively) and FA using commercial reagents (interassay coefficient of variation 1.65%). All the individuals underwent a 75-g oral glucose tolerance test, which revealed significant correlations between the values of the three glycated proteins and the four plasma glucose concentrations measured as well as the sum of these glucose concentrations, sigma BS (GA, $r = 0.80$; HbA1c, $r = 0.80$; FA, $r = 0.65$). On the basis of the test, 130 of the subjects were classified as normal (N), 123 as borderline and 49 as having *diabetes* mellitus (D) according to the criteria of the Japan *Diabetes* Society. Of the 123 borderline cases, 26 showed impaired glucose tolerance (IGT) according to the WHO criteria. The normal group values of GA, HbA1c and FA were $17.8 \pm 0.17\%$ (mean \pm SEM), $5.02 \pm 0.03\%$, and 2.55 ± 0.02 mM/l, respectively. Borderline and IGT subjects had significantly more GA and HbA1c than normal but not more FA (P less than 0.01). We divided the subjects into 10 groups on the basis of their sigma BS values; those with values higher than 671 ± 4.7 mg/dl had significantly more GA and HbA1c than normal, while those with values higher than 1068 ± 40.9 mg/dl (the most extreme cases) had significantly more FA.(ABSTRACT TRUNCATED AT 250 WORDS).

TI *Screening* *for* *diabetes:* does measurement of serum fructosamine help?

SO Diabetic-Med. 1988 Oct. 5(7). P 648-52.

JT DIABETIC MEDICINE.

LG English (EN).

AB The diagnostic sensitivity and specificity *for* *diabetes* of serum fructosamine levels and fasting venous blood glucose concentrations were compared in 613 subjects during a *diabetes* community *screening* programme of 1049 adult Muslim Asians in Dar es Salaam, Tanzania. Using WHO (1985) criteria 228 had impaired glucose tolerance (IGT), 41 had previously been diagnosed as having *diabetes* while 32 had newly recognized *diabetes.* The mean (+/- SD) serum fructosamine levels were 20.9 +/- 3.2, 21.6 +/- 3.2, 23.9 +/- 4.9, and 30.1 +/- 7.9 (umol g-1 albumin) in subjects with normal glucose tolerance, IGT, newly diagnosed *diabetes,* and previously diagnosed *diabetes,* respectively (p less than 0.001 *for* differences between groups). The specificity of values above the mean +2SD normal was 99% *for* abnormal glucose tolerance with a sensitivity of only 22% *for* *diabetes.* The predictive values were 44% and 97% *for* positive and negative results, respectively. Very little difference from normal was found *for* IGT subjects. Expressing fructosamine values in absolute terms or per gram albumin made little difference to sensitivity and specificity. The sensitivity was only 32% *for* fasting blood glucose greater than or equal to 6.7 mmol l-1, 73% *for* values greater than or equal to 5.5 mmol l-1, and 100% *for* fasting blood glucose greater than or equal to 4.5 mmol l-1. It is concluded that both serum fructosamine and fasting blood glucose are poor *screening* and diagnostic tests *for* *diabetes* and *for* IGT, and that glucose loading is required.

AB The World Health Organization has recommended a single 2-h
post-glucose load blood glucose level as a *screening* test *for*
diabetes mellitus in epidemiological surveys. We have assessed its
characteristics, when compared with a full supervised glucose
tolerance test (OGTT), in estimating prevalence, and in diagnosing
diabetes in the individual patient. A stratified sample of 223 of
1040 subjects who had participated in a diabetic survey that utilized
a single capillary 2-h blood glucose estimation as a *screening* test
were recalled *for* formal glucose tolerance testing. The numbers of
subjects with *diabetes* at *screening* and at recall were similar
(14/212, 6.6%; 13/216, 6.0%) but only 9 subjects were so classified
on both occasions. Thirty-five subjects (16.5%) were suspected of
having impaired glucose tolerance (IGT) at *screening,* and 52 (24.1%)
at recall. There was substantial reclassification from *screening*
IGT, with 3/35 worsening to *diabetes,* and 10/35 returning to normal.
Capillary 2-h glucose levels gave an accurate assessment of the
prevalence of *diabetes* but underestimated that of IGT. On the full
OGTT, little difference in classification was found when the values
of fasting and 1-h blood glucose were used in addition to those of
the 2-h blood glucose used alone. The 2-h glucose had a
within-subject coefficient of variation of 32.4% which produced
substantial reclassification of subjects with levels close to the
diagnostic levels *for* *diabetes,* and this implies that such
individuals should not be classified as having *diabetes* on the basis
of a single glucose tolerance test.(ABSTRACT TRUNCATED AT 250 WORDS).

AB *Diabetes* mellitus in nonpregnant adults is a chronic affliction that leads to significant vascular and neuropathic disease. *Diabetes* during pregnancy can lead to perinatal complications. Both of these types of *diabetes* are common, often asymptomatic, and readily diagnosable by glucose tolerance testing. As a result, *screening* can identify many previously undiagnosed patients. However there is only limited evidence that *screening* results in net therapeutic benefit. In the case of gestational *diabetes,* controlled trials indicate that hypoglycemic therapy decreases the frequency of macrosomia, but has no effect on perinatal mortality. Our analyses indicate that *screening* *for* gestational *diabetes* is a low-cost intervention that produces a small expected benefit. *Screening* *for* *diabetes* in the nonpregnant adult (almost always a type II diabetic) is not recommended, because the link between improving glucose control and reducing diabetic complications is currently too weak. *Screening* might be reasonable *for* particular patients, *for* example, obese persons who would be spurred to lose weight by a demonstration of glucose intolerance. *Screening* *for* type I *diabetes* followed by immunomodulating therapy is still too experimental *for* confident analysis. JT *DIABETES* RESEARCH.
LG English (EN).
AB The feasibility of using a blood-glucose reflectance meter to
identify subjects with abnormal glucose tolerance in a
community-based *screening* programme *for* *diabetes* mellitus has been
assessed. 530 (51.0%) of 1,040 screened subjects had a finger-prick
capillary blood-glucose level estimated 2 h after a 75 g oral glucose
load. Blood-glucose estimations were performed on this sample by an
automated glucose-oxidase method and by a reflectance meter system
(Reflocheck, BCL (London) Ltd., Lewes, East Sussex, UK).
Blood-glucose values measured by the meter were found to be higher
than those assayed by the glucose-oxidase method by a mean ratio of
1.16:1. This overestimation could not wholly be explained by the
meter being calibrated to measure plasma- rather than whole
blood-glucose. This ratio was constant in specimens assayed by the
glucose-oxidase method within 24 h of sampling or within 7 days of
sampling. The meter system gave a good approximation of the
prevalence of DM in the sample (14 "diabetics" identified by the
meter, 15 by the glucose-oxidase 2hBG). The optimal test
characteristics of the meter 2hBG as a *screening* test *for* DM were at
a cut-off level of 9.7 mmol/l (sensitivity and specificity 98.4%, CI
85.8-100%, *for* sensitivity, 97.3-99.5% *for* specificity). However, in
order to be 100% sensitive *for* DM, confirmatory GTTs would be
necessary on all subjects with meter 2hBG greater than 9.5 mmol/l,
providing a specificity of 98.2% (CI 97.0-99.7%). The unit cost of
detecting 1 case of DM using a single meter became cheaper than using
the laboratory glucose-oxidase method when 143 subjects had been
screened. Author-abstract.

TI *Screening* *for* *diabetes* in pregnancy: is a random blood glucose enough?

SO Diabetic-Med. 1987 Mar-Apr. 4(2). P 160-3.

JT DIABETIC MEDICINE.

LG English (EN).

AB It has been suggested that a single random blood glucose measurement, timed in relation to food, can be used to determine those women needing a formal oral glucose tolerance test *for* the detection of gestational *diabetes.* One hundred and ten pregnancies have been screened to compare the results of a formal oral glucose tolerance test with timed venous plasma glucose measurements taken throughout the day. At the suggested thresholds of 6.1 mmol/l (within 2 h of eating) and 5.6 mmol/l (at greater than 2 h of food), random blood glucose testing is specific and excludes most normal women. However, the sensitivity of the test is low, and the majority of those with impaired glucose tolerance would be missed. Random blood glucose measurement is not a sufficiently sensitive method *for* detecting gestational *diabetes* as presently defined. Author-abstract.

LG English (EN).

AB Undetected gestational *diabetes* mellitus (GDM) is associated with a

two- to fivefold increase in perinatal morbidity and mortality. Widespread *screening* of the obstetric population (resulting in identification and treatment) should reduce these rates. Seven hundred ninety-eight women were examined during a 13-mo period of universal glucose challenge testing (GCT). A total of 2.8% of the population had an abnormal oral glucose tolerance test (OGTT). Thirty percent of those with an abnormal OGTT were less than 25 yr old. The specificity of a 1-h GCT (50-g carbohydrate load) using a threshold of either 140 or 150 mg/dl was compared with that of a 2-h specimen using a threshold of 118 mg/dl to determine whether the cost of *screening* could be reduced. One- and 2-h specimens were obtained in 347 of these women. A 34% reduction in the number of follow-up OGTTs required would have been achieved if a 2-h specimen had been used as the index instead of a 1-h specimen (P less than .05). As a result, the (direct and indirect) cost per patient identified with GDM would have declined 23.5%--from \$866 to \$662. No comment concerning the actual false-negative rate of either the 1- or 2-h GCT can be made because only select women underwent an OGTT. To assess the validity of the 2-h threshold, an OGTT was performed in an additional 190 women if either the 1- or 2-h screen was abnormal. The results were confirmatory: the 2-h screen would have reduced the cost per case identified by 32% in this small group. *Screening* on the basis of past medical history clearly lacked sensitivity and cost efficacy in comparison with the GCT and should be abandoned as a practice. Author-abstract.

TI Audit in general practice by a receptionist: a feasibility study.

SO BMJ. 1991 Mar 9. 302(6776). P 573-6.

JT BMJ.

PT JOURNAL ARTICLE (ART).

LG English (EN).

AB OBJECTIVE--To examine whether audit can be done *cost* effectively by a practice's receptionist. DESIGN--The practice set goals for various aspects of care, and forms were devised for the receptionist to collect, analyse, and present data to assess whether these goals had been achieved in the previous year. SETTING--Six doctor practice in south London looking after 11,500 patients. MAIN OUTCOME MEASURES--Ability of receptionist to present data showing the level of attainment of the practice's goals; time spent on audit by receptionist each week. RESULTS--The practice set goals for immunisation; follow up of patients with abnormal cervical smears; frequency of recording of *blood* *pressure* and smoking habit; *screening* of patients over 75; care of diabetic patients and patients with serious mental illness; antenatal care; variations in workload; and availability of appointments. The receptionist was able to audit all these tasks in four hours a week; this increased her job satisfaction and extended her skills. A small amount of regular supervision was necessary--roughly 30 minutes a week in the first year of the study and 30 minutes a fortnight in the second--to ensure accuracy and deal with any difficulties that arose. CONCLUSION--The method developed enabled a receptionist to audit aspects of the practice *cost* effectively. There is great scope for enlarging the conventional role of the receptionist.  TI *Screening* and surveillance of pregnancy hypertension--an economic
 approach to the use of daycare.
 SO Baillieres-Clin-Obstet-Gynaecol. 1990 Mar. 4(1). P 89-107.
 JT BAILLIERES CLINICAL OBSTETRICS AND GYNAECOLOGY.
 LG English (EN).
 AB Frequent measurement of *blood* *pressure* is an accepted part of routine
 outpatient antenatal care. Women found to have mild hypertension may
 be further monitored for signs of progressive disease, while women
 with proteinuria or severe hypertension may be admitted for more

intensive surveillance or treatment. In practice, the course and ultimate severity of this disorder are unpredictable and women with mild hypertension are frequently admitted. Recently, daycare has grown as an option for assessing women with hypertension as it offers the advantage of more extensive evaluation than is possible at an outpatient clinic and is widely assumed to be more *cost-effective* than conventional management. However, its use in obstetrics has not been subject to a formal economic appraisal. Such an evaluation is currently being carried out in two hospitals in Scotland, one of which uses daycare and inpatient admissions in the management of hypertension and one of which uses domiciliary midwife visits as well as hospital beds. Preliminary results suggest that the pregnancy outcome in terms of birthweight, gestation at delivery, admission to a special unit, etc., are the same in the two units for women with mild hypertension (diastolic 90-99 mmHg, no proteinuria). The *costs* per patient were less in the hospital with a daycare unit. These lower individual *costs,* however, do not mean that the overall *costs* to the health service are less in a hospital with daycare. This will depend on the average number of visits to daycare for women with mild hypertension, the proportion of hypertensive women receiving daycare, whether freed inpatient beds are closed or redeployed, and the capital *costs* of establishing a day unit. Data has also been collected on women's *costs* and views which will ultimately be presented and should play a part in any decision to implement or continue daycare. Author-abstract.

TI A review of *cost-effectiveness* analyses.

SO Med-J-Aust. 1990 Aug 6. 153 Suppl. P S20-3.

JT MEDICAL JOURNAL OF AUSTRALIA.

LG English (EN).

AB A large number of *cost-effectiveness* analyses has been published over the last 16 years. *Cost-effectiveness* ratios *(costs* per year of life gained or quality adjusted year of life gained) derived through *cost-effectiveness* analysis can be used to compare the efficiency of different health-care programmes, although such comparisons should be made cautiously because of the uncertainties associated with many estimates of *cost* and effectiveness. Considering cardiovascular disease control programmes, for example, some preventive strategies, such as advice to quit smoking, or exercise programmes, are more *cost-effective* than antihypertensive treatment or coronary artery bypass grafting. However, cholestyramine therapy for prevention of coronary heart disease is less *cost-effective* than either of these treatments, and there are marked variations in the *cost-effectiveness* of many interventions, with factors such as the age group treated, frequency of treatment and level of parameters such as diastolic *blood* *pressure,* playing a role. Cancer control programmes are also considered in this paper. *Cost-effectiveness* analysis can be useful for assessing the relative *costs* and effectiveness of different programmes, but all relevant factors for policy-making and resource allocation can rarely be incorporated in a single analysis.

screening in primary care.

SO Med-Care. 1989 Mar. 27(3). P 297-305.

JT MEDICAL CARE.

PT CLINICAL TRIAL (CTR).

LG English (EN).

AB In a randomized, controlled trial (N = 8,298) the authors compared three ways of encouraging patients in a large family practice to obtain a *blood* *pressure* check. Working from computerized medical records at a teaching family-medicine center, the study included patients aged 18 years and over who had not had a *blood* *pressure* measurement during the previous year. In a normal-care control group, 21.1% of those due for a *blood* *pressure* reading obtained one during the trial year. In one intervention group, a computer-generated message reminded the doctor to check the *blood* *pressure* of patients who happened to visit the center for an appointment; 30.7% of patients allocated to this group were checked. In the second group, the nurse contacted patients by telephone and encouraged 24.1% of those who were due for a check to obtain one. Sending a letter to patients in the third group yielded a 35.7% compliance rate. Considering the *costs* of the three interventions, the physician reminder was the most *cost* effective, followed by the letter reminder. Although statistically significant, the impact of the reminders was modest. A better approach might involve a combination of routine reminders to the physician, followed by letters to noncompliant patients. Author-abstract.

7. Developmental ,mfeasibility, or pilot studies

The first step in ascertaining the feasibility of conducting long-term research on the health effects of the radiation from the accident requires the enumeration of the population. Thus the composition of the proposed study population must be described, numbers, age distribution, extent of exposure through directed, biological, physical or geographical reconstruction.

Existing research will be evaluated by documentation providing the following types of information to be reviewed by the Consortium's Scientific Council;

1. Past research training record for both the program and the designated preceptors in terms of the rate at which former trainees establish independent and productive research careers
2. Past research training record in terms of the success of former trainees in obtaining individual awards such as fellowships, career awards, and research grants for further development
3. Objectives, design, and direction of the research training program
4. Caliber of preceptors as researchers including successful competition for research support
5. Training environment including the institutional commitment, the quality of the facilities, and the availability of research support
6. Recruitment and selection plans for appointees and the availability of high quality candidates
7. The record of the research training program in retaining health-professional post-doctoral trainees for at least two years in research training or other research activities
8. When appropriate, the concomitant training of health-professional post-doctorates (e.g., individuals with the M.D., D.O., D.D.S.) with basic science post-doctorates (e.g., individuals with a Ph.D., Sc.D.) will receive special consideration

Following scientific-technical review, the application will receive a second-level review by the appropriate National Advisory Council.

AWARD CRITERIA

Applications recommended for approval by the appropriate National
--more-- Press [space] to continue, [q] to quit Advisory Council will be considered for funding on the basis of overall scientific and technical merit of the research as determined by peer review, program needs and balance, and availability of funds.

--more-- Press [space] to continue, [q] to quit APPLICATION. POTENTIAL APPLICANTS
SHOULD OBTAIN THE RFA AND THE
ENVIRONMENTAL HEALTH SCIENCES CENTER GRANT APPLICATION GUIDELINES FROM
THE CONTACT NAMED IN INQUIRIES, BELOW.

PURPOSE

The overall intent of this National Institute of Environmental Health Sciences (NIEHS) program is to establish multi-disciplinary research programs supported by a core center (P30). The focus is on environmentally related health problems of economically disadvantaged and/or underserved populations. The first step in this process is the current RFA that requests developmental grant (P20) applications from institutions or consortia of institutions wishing to develop multi-disciplinary core center (P30) grants with this theme.

This RFA has a single receipt date, September 4, 1992. However, the NIEHS intends to announce additional receipt dates for developmental grants on this theme periodically.

HEALTHY PEOPLE 2000

--more-- Press [space] to continue, [q] to quit
The Public Health Service (PHS) is committed to achieving the health promotion and disease prevention objectives of "Healthy People 2000," a PHS-led national activity for setting priority areas. This RFA, Developmental Grant: Environmental Health Sciences Centers, is related to the priority area of environmental health. Potential applicants may obtain a copy of "Healthy People 2000" (Full Report: Stock No. 017-001-00474-0) or "Healthy People 2000" (Summary Report: Stock No. 017-001-00473-1) through the Superintendent of Documents, Government Printing Office, Washington DC 20402-9325 (telephone 202-783-3238).

ELIGIBILITY REQUIREMENTS

Applications may be submitted by domestic for-profit and non-profit organizations, public and private. Applications from minority individuals and women are encouraged.

MECHANISM OF SUPPORT

This RFA will use the National Institutes of Health (NIH) exploratory
--more-- Press [space] to continue, [q] to quit grant (P20). The maximum requested amount of each application may not exceed \$175,000 direct cost per year. The total project period may not exceed three years. It is estimated that approximately one to three awards will be made.

It is important to note that the award of a developmental grant by the NIEHS does not imply a commitment to future funding of any resulting research or center grant applications. These must be submitted separately and will be evaluated on the basis of their own merit. The core center (P30) grant requires a research grant base of at least \$1,000,000 of outside peer reviewed awards related to environmental health problems, particularly focusing on economically disadvantaged and/or underserved populations. Therefore, it will require a substantial effort during the award period of the P20 grant to achieve the level of research support base necessary to qualify and compete successfully for a core center grant.

FUNDS AVAILABLE

The funding level for NIEHS developmental grants will be \$175,000
--more-- Press [space] to continue, [q] to quit direct costs per year for a maximum of three years. It is anticipated that one to three developmental grants will be awarded depending upon the appropriation of funds for this purpose and the quality of the applications received. The awards are not renewable and supplements are not allowed.

RESEARCH OBJECTIVES

Most Americans want to live long and healthy lives, and the majority achieve that goal. In general, however, economically disadvantaged and/or underserved populations are less likely to achieve this goal. At every stage of life, these populations suffer disproportionate levels of morbidity and mortality.

The primary purpose of the NIEHS developmental grants will be to provide support for a group of investigators to develop interdisciplinary collaborations and strategies, to obtain preliminary results to demonstrate ^[[7mfeasibility^[m, and to develop a research program addressing the above-cited PURPOSE of the NIEHS in this RFA. The resulting program will then be used as the basis for an application for
--more-- Press [space] to continue, [q] to quit other NIEHS project grants and ultimately a core center grant (P30).
The objectives for an NIEHS developmental grant may include, but are not limited to:

- o Preliminary or ^[[7mfeasibility^[m studies to gather sufficient data to

demonstrate the potential of an idea or the validity of an approach, to acquire or demonstrate technical competence, or to evaluate other technical factors involved in the development of a project that addresses the goal of this initiative;

- o Recruitment of new investigators whose expertise would strengthen the overall research project base in a subsequent core center grant application;

- o Inter- or intra-institutional planning to develop research strategies, including the establishment of a timetable or milestones, for the development of grant applications that are prerequisite for the NIEHS Core Center grant application.

STUDY POPULATIONS

--more-- Press [space] to continue, [q] to quit

SPECIAL INSTRUCTIONS FOR INCLUSION OF WOMEN AND MINORITIES IN CLINICAL RESEARCH STUDIES

For projects involving clinical research, NIH requires applicants to give special attention to the inclusion of women and minorities in study populations. If women or minorities are not included in the study populations for clinical studies, a specific justification for this exclusion must be provided. Applications without such documentation will not be accepted for review.

LETTER OF INTENT

Prospective applicants are asked to submit, by August 14, 1992, a letter of intent that includes a descriptive title of the proposed research, the name, address, and telephone number of the Principal Investigator, the identities of other key personnel and participating institutions, and the number and title of the RFA in response to which the application may be submitted.

--more-- Press [space] to continue, [q] to quit to as Fogarty International Research Collaboration Awards (FIRCAs) to

U.S. grantee institutions to facilitate cooperation and collaboration between U.S. scientists and scientists in Central and Eastern Europe, Latin America, and the non-U.S. Caribbean. This announcement expands the FIRCA program to include cancer-related collaborative research with scientists located in Sub-Saharan Africa. This new effort is supported by the National Cancer Institute (NCI). FIRCAs provide funds to foreign collaborators, through the U.S. grantee institution, for equipment and supplies at their home institution, and for travel expenses for both the U.S. Principal Investigator and the foreign collaborator. These awards are intended to support the new and expanded research efforts of U.S. scientists who are Principal Investigators of currently funded National Institutes of Health (NIH) research project grants on the general scientific subject of the

proposed collaboration.

ELIGIBILITY REQUIREMENTS

U.S. scientists who are Principal Investigators of NIH research project grants (R series, P series, or U-01 series) that will be --more-- Press [space] to continue, [q] to quit active and funded during the proposed grant award period (up to three years) are eligible. The small grants will be made for work conducted in cooperation with scientists only in countries located in the geographical regions commonly known as Central and Eastern Europe (including the former USSR and the Baltic Republics), Latin America, the non-U.S. Caribbean, and for cancer-related research, Sub-Saharan Africa. The foreign collaborator must hold a position at a public or private non-profit institution that will allow him or her adequate time and provide appropriate facilities to conduct the proposed research.

MECHANISMS OF SUPPORT

The small grants (R03) will provide up to \$20,000 per year for up to three years in direct costs. Funds may be used for materials, supplies, and equipment for the foreign scientist's research laboratory and for travel expenses for the Principal Investigator and/or the foreign collaborator and their research associates, as justified by the scientific needs of the project. No salaries or stipends for any of the collaborators, students, or technical --more-- Press [space] to continue, [q] to quit assistants will be offered under these awards. Applicants must request support to conduct research not already being supported by the U.S. investigator's research grant; however, the research proposal should be an extension of or related to the currently funded research project. The awards will be made to U.S. institutions, which will be responsible for the expenditures. The minimum small grant project period will be for one year; the maximum will be for three years. Indirect costs will be calculated on the basis of the off-site rates of the U.S. sponsoring institution. The award of this small grant is non-renewable, and the NIH awarding unit of the "parent" grant is under no obligation to continue support for the foreign research component as a component of a recompetiting "parent" grant.

RESEARCH OBJECTIVES

The main objective of this program is to facilitate collaborative research efforts between U.S. and foreign scientists that will expand and enhance the NIH-supported research program of the U.S. Principal Investigator, while at the same time benefiting the scientific --more-- Press [space] to continue, [q] to quit interests of the collaborating foreign scientist. These small grants

will provide funds to purchase supplies, materials, and small equipment items necessary to conduct the collaborative research in the foreign scientist's research laboratory at a non-profit public or private institution in the eligible countries. These awards will also provide travel support, as necessary to conduct the collaborative research effort, for the U.S. and/or the foreign collaborator(s). All biomedical and behavioral research topics supported by the NIH are eligible for inclusion under this program in Central and Eastern Europe, Latin America, and the non-U.S. Caribbean. Research collaboration with scientists in Sub-Saharan Africa is limited to cancer-related research only. The U.S. Principal Investigator must show evidence of ongoing NIH research support in areas related to the small grant application, and this support must be available during the entire proposed small grant award period. The application must demonstrate that the effort will enhance the scientific contributions of both the U.S. and foreign scientists and strengthen the contribution to the NIH-sponsored research effort.

--more-- Press [space] to continue, [q] to quit STUDY POPULATIONS

SPECIAL INSTRUCTIONS TO APPLICANTS REGARDING IMPLEMENTATION OF NIH POLICIES CONCERNING INCLUSION OF WOMEN AND MINORITIES IN CLINICAL RESEARCH STUDY POPULATIONS

NIH policy is that applicants for NIH clinical research grants and cooperative agreements are required to include minorities and women in study populations so that research finding can be of benefit to all persons at risk of the disease, disorder or condition under study; special emphasis must be placed on the need for inclusion of minorities and women in studies of diseases, disorders and conditions which disproportionately affect them. This policy is intended to apply to males and females of all ages. If women or minorities are excluded or inadequately represented in clinical research, particularly in proposed population- based studies, a clear compelling rationale must be provided.

The composition of the proposed study population must be described in terms of gender and racial/ethnic group. In addition, gender and --more-- Press [space] to continue, [q] to quit racial/ethnic issues should be addressed in developing a research design and sample size appropriate for the scientific objectives of the study. This information must be included in the form PHS 398 (rev. 9/91) in Sections 1-4 of the Research Plan AND summarized in Section 5, Human Subjects. Applicants are urged to assess carefully the feasibility of including the broadest possible representation of minority groups. However, NIH recognizes that it may not be feasible or appropriate in all research projects to include representation of the full array of United States racial/ethnic minority populations (i.e., Native Americans (including American Indians or Alaskan

Natives), Asian/Pacific Islanders, Blacks, Hispanics). The rationale for studies on single minority population groups must be provided.

For the purpose of this policy, clinical research is defined as human biomedical and behavioral studies of etiology, epidemiology, prevention (and preventive strategies), diagnosis, or treatment of diseases, disorders or conditions, including but not limited to clinical trials.

The usual NIH policies concerning research on human subjects also --more-- Press [space] to continue, [q] to quit apply. Basic research or clinical studies in which human tissues cannot be identified or linked to individuals are excluded. However, every effort should be made to include human tissues from women and racial/ethnic minorities when it is important to apply the results of the study broadly, and this should be addressed by applicants.

If the required information is not contained within the application, the review will be deferred until the information is provided.

Peer reviewers will address specifically whether the research plan in the application conforms to these policies. If the representation of women of minorities in a study design is inadequate to answer the scientific questions(s) addressed AND the justification for the selected study population is inadequate, it will be considered a scientific weakness or deficiency in the study design and will be reflected in assigning the priority score to the application.

All applications for clinical research submitted to NIH are required to address these policies. NIH funding components will not award grants or cooperative agreements that do not comply with these --more-- Press [space] to continue, [q] to quit policies.

APPLICATIONS PROCEDURES

Applications are to be submitted by the U.S. Principal Investigator on the standard grant application form PHS 398 (rev. 9/91), available at most institutional offices of sponsored research and from the Office of Grants Inquiries, Division of Research Grants, National Institutes of Health, 5333 Westbard Avenue, room 449, Bethesda, MD 20892, telephone (301) 496-7441. The deadlines for receipt of applications are October 1, February 1, and June 1 of each year. Special instructions are necessary and are available from the address below. Credentials for the foreign collaborators must be included with the application and the collaborative arrangements described in a letter signed by both investigators. Applicants must list the active NIH research grant(s) that will be held during the proposed project period of this award. The foreign laboratory collaborating with the Principal Investigator of the small grant must be located in the countries of Central and Eastern Europe (including the former

USSR and the Baltic Republics), Latin America, the non-U.S. Caribbean
--more-- Press [space] to continue, [q] to quit and for cancer-related research,
Sub-Saharan Africa.

The title and number of the announcement must be typed on line 2a of
the face page of the application. The complete original and five
legible copies must be sent or delivered to:

Division of Research Grants
National Institutes of Health
Westwood Building, Room 240
Bethesda MD 20892**

REVIEW PROCEDURES

Applications will be assigned for review to, and awards will be made
by, the FIC, utilizing the customary NIH peer review process.
Scientific and technical merit will be evaluated by a Fogarty
International Center initial review group. Second level review will
be provided by the Fogarty International Center Advisory Board.

AWARD CRITERIA

--more-- Press [space] to continue, [q] to quit
Initial award decisions will be announced within a month following
each board meeting and will be based on the scientific merit of the
applications and the availability of funds.

Applications may be submitted by domestic and foreign, non-profit and for-profit, public and private organizations, such as universities, colleges, hospitals, laboratories, units of State and Local --more-- Press [space] to continue, [q] to quit governments, and eligible agencies of the Federal Government. However, foreign institutions are not eligible for the First Independent Research Support and Transition (FIRST) Award (R29) and the career development awards (K04, K08, K11). Applications from minority individuals and women are encouraged.

MECHANISMS OF SUPPORT

Support will be offered through research project grants (R01), FIRST Awards (R29), research fellowship training awards (F32, F33), and research career development awards (K04, K08, K11).

RESEARCH OBJECTIVES

Sports and exercise activity in youth are critical to developing and maintaining physical fitness and general well-being. These fitness patterns established in youth may provide the basis for a healthy life-style throughout adult life. The occurrence of injuries has been accepted as a natural risk associated with exercise and especially with sports participation. Of the estimated 8 million youth participating --more-- Press [space] to continue, [q] to quit in sports at the junior high and high school level, approximately 25 percent incurred some form of injury. Therefore, the physical and financial impact is significant.

One means of reducing these injuries is to understand the nature and risk factors for sports injuries and to seek preventive measures to reduce the occurrence. Injury surveillance approaches have led to important changes in rules and equipment to reduce the rate of injury. In one case, trampolines, the nature of the sport could not be modified to improve safety, therefore, the sport has been eliminated.

On April 8-9, 1991, at the Lister Hill Center of the NIH a conference was held on Sports Injuries in Youth: Surveillance Strategies. This meeting was co-sponsored by the National Advisory Board for Arthritis and Musculoskeletal and Skin Diseases, NIAMS, and the Centers for Disease Control. The purpose of the Conference was to examine the various factors required to develop and operate a surveillance system. Successful systems and problem areas were described. The resulting information will provide guidance for researchers entering areas of investigation involving development and utilization of reliable data --more-- Press [space] to continue, [q] to quit bases in the field of scholastic sports injury. Published proceedings from the conference are available from the contact person listed below under INQUIRIES.

The epidemiologic definition of surveillance is the dynamic, close, and continued watchfulness over the distribution and trends of disease occurrence through systematic collection, tabulation, and analysis of relevant mortality and morbidity data. Essential steps in this process include data collection, entry, processing, analysis, interpretation, and presentation. A weakness in any of these procedures may result in incomplete, inaccurate, improper, or poorly disseminated findings. One of the critical elements in analyzing sports surveillance data is the determination of the rate (incidence/number of persons at risk) of injury. For example, all players on a basketball team may not be at equal risk, since some may not even enter the game. Issues such as these are well defined in the conference proceedings.

The suggested areas for future research that were developed during the conference were defined in the proceedings as:

--more-- Press [space] to continue, [q] to quit o Developing surveillance systems for consistent national data collection;
o Developing a national sports injury data base;
o Injury characterization and intervention schemes;
o Coordination of data from diverse sources;
o Developing methods for "small area sampling" of special injury situations;
o Evaluating re-injury rates and risks;
o Expanding surveillance to include intramural and extra-scholastic sports;
o Expanding injury surveillance to include primary grades;
o Comparing injury rates and conditions to college and professional sports;
o Considering a wide range of external factors that may add to risks;
and
o Developing and evaluating instructional prevention programs.

These areas of research are neither prioritized nor meant to be restrictive. Investigators are encouraged to submit applications in any meritorious area of research responsive to the general research objectives of this Program Announcement. In addition to projects that specifically address surveillance methodology to uncover risks of and the nature of injuries, the NIAMS will consider to be responsive to this announcement applications that include biomechanical, biochemical, or other approaches to elucidating the mechanism of injury. Such related studies should either (1) be a component of applications for surveillance-based research or (2) be based on the findings of other surveillance data indicating that a particular mechanism may be the cause of injury.

The project should be founded on a strong hypothesis as evidenced by preliminary data of the investigator or others. All data collection

and statistical procedures should be fully defined and justified.

STUDY POPULATIONS

SPECIAL INSTRUCTIONS TO APPLICANTS REGARDING IMPLEMENTATION OF NIH POLICIES CONCERNING INCLUSION OF WOMEN AND MINORITIES IN CLINICAL RESEARCH STUDY POPULATIONS

--more-- Press [space] to continue, [q] to quit NIH and ADAMHA policy is that applicants for NIH/ADAMHA clinical research grants and cooperative agreements are required to include minorities and women in study populations so that research findings can be of benefit to all persons at risk of the disease, disorder or condition under study. Special emphasis must be placed on the need for inclusion of minorities and women in studies of diseases, disorders and conditions which disproportionately affect them. This policy is intended to apply to males and females of all ages. If women or minorities are excluded or inadequately represented in clinical research, particularly in proposed population-based studies, a clear compelling rationale must be provided.

The composition of the proposed study population must be described in terms of gender and racial/ethnic group. In addition, gender and racial/ethnic issues should be addressed in developing a research design and sample size appropriate for the scientific objectives of the study. This information must be included in Form PHS 398 in Sections 1-4 of the Research Plan and then summarized in Section 5, Human Subjects. Applicants are urged to assess carefully the feasibility of including the broadest possible representation of minority groups.

--more-- Press [space] to continue, [q] to quit However, NIH recognizes that it may not be feasible or appropriate in all research projects to include representation of the full array of United States racial/ethnic minority populations (i.e., Native Americans (including American Indians or Alaskan Natives), Asian/Pacific Islanders, Blacks, and Hispanics). The rationale for studies on single minority population groups must be provided.

For the purpose of this policy, clinical research is defined as human biomedical and behavioral studies of etiology, epidemiology, prevention (and preventive strategies), diagnosis, or treatment of diseases, disorders or conditions, including, but not limited to, clinical trials.

The usual NIH policies concerning research on human subjects also apply. Basic research or clinical studies in which human tissues cannot be identified or linked to individuals are excluded. However, every effort should be made to include human tissues from women and racial/ethnic minorities when it is important to apply the results of the study broadly, and this should be addressed by applicants.

--more-- Press [space] to continue, [q] to quit For foreign awards, the policy on inclusion of women applies fully; since the definition of minority differs in other countries, the applicant must discuss the relevance of research involving foreign population groups to the United States' populations, including minorities. If the required information is not contained within the application, the review will be deferred until the information is provided.

Peer reviewers will address specifically whether the research plan in the application conforms to these policies. If the representation of women or minorities in a study design is inadequate to answer the scientific question(s) addressed and the justification for the selected study population is inadequate, it will be considered a scientific weakness or deficiency in the study design and will be reflected in the priority score assigned to the application.

All applications for clinical research submitted to NIH are required to address these policies. NIH funding components will not award grants or cooperative agreements that do not comply with these policies.

--more-- Press [space] to continue, [q] to quit APPLICATION PROCEDURES

Applications are to be submitted on grant application form PHS 398 (rev. 9/91), except for individual fellowship applications which must be submitted on form PHS 416-1 (rev. 10/91). Applications will be accepted at the standard application deadlines indicated in the application kits.

Application kits are available at most institutional business offices and may also be obtained from the Office of Grants Inquiries, Division of Research Grants, National Institutes of Health, Westwood Building, Room 449, Bethesda, MD 20892, telephone 301/496-7441. The title and number of the announcement must be typed in Section 2a on the face page of form PHS 398.

have applied for IAIMS funding in the past, may apply to the revised program.

MECHANISM OF SUPPORT

The mechanism of support for this PA is the medical library resource grant (G08). This grant mechanism only funds direct costs.

PROGRAM OBJECTIVES

Background

In 1983 the NLM initiated an award program to provide "assistance to medical centers and health science institutions for planning and --more-- Press [space] to continue, [q] to quit development projects leading to the implementation of Integrated Academic Information Management Systems (IAIMS)." The program announcement went on to say, "IAIMS are institution-wide computer networks that link and relate library systems with individual and institutional databases and information files, within and external to the institution, for patient care, research, education, and administration. The goal is to create an organizational mechanism within health institutions to more effectively manage the knowledge of medicine, and to provide for a system of comprehensive information access."

During the next decade over seventy institutions applied for IAIMS grants in one or another of the 3 defined phases, and through FY 1991 26 awards had been made to 16 institutions. The importance of information management today is as great as ever, but the program elements as originally defined by NLM deserve re-evaluation. Lessons have been learned from a decade of experience; furthermore, the climate has changed significantly as a number of institutions made extensive investments in information systems in recent years; most importantly, the advent of the High Performance Computing and Communications --more-- Press [space] to continue, [q] to quit Initiative (HPCC) has dramatically enriched the possibilities of information transfer, while increasing the complexity of information management.

The NLM is the lead biomedical organization in the federal Government's HPCC initiative. The HPCC program recognizes "that unprecedented computational power and its creative use are needed to investigate and understand a wide range of scientific and engineering 'grand challenge' problems." (1) Some of the problems identified are of obvious interest to biomedicine: National Research and Education Network (NREN), biotechnology, transmission of digital images, intelligent gateways to retrieve information from several life sciences databases, and innovations in educational techniques, among others.

Accordingly, NLM is revising its IAIMS program with:

- o A name change: replacing "academic" with "advanced" recognizes the wide applicability of the IAIMS concept and the need to incorporate new technology
- o Fusion of the old phases II and III (model and implementation) into --more-- Press [space] to continue, [q] to quit one operational phase
- o Changes in the level of support
- o Some modification of the scope and conditions of the grant
- o Incorporation of HPCC into the NLM vision of an integrated information management system.

The Integrated Advanced Information Management Systems (IAIMS) Program

The revised IAIMS program has two phases: A planning phase, and an operational phase.

1. IAIMS Planning Phase

"New" IAIMS planning phase resembles Phase I of the "old" IAIMS. Various models can be used in information systems planning, but all applications should include some form of self-study and allow for certain key elements:

- o A description of the institution's information management resources, current and five-year projection;
- more-- Press [space] to continue, [q] to quit o Development of an institutional information policy that addresses both short-term and long-term goals;
- o Identification of leadership for planning;
- o Broad involvement of clinical and basic science faculty, administration, and students;
- o Specification of desired strategic outcomes;
- o An outline of the planning process, including goals and timetables; and
- o A comprehensive view that considers information needs of patient care, research, education, and administration.

The outcome of planning activities is the development of an institutional Information Management Plan, which should include information resources management policies, an analysis of functions and responsibilities of major information database managers, and a description of how IAIMS will be developed, organized, and managed.

A total separation between planning and operations is not mandated; institutions vary widely in the information system already in place at the time of application. An institution may, if it wishes, use or --more-- Press [space] to continue, [q] to quit introduce some operational elements during this planning period (for example, an E-mail system.)

The IAIMS planning grant may be for up to \$150,000 per year for one to two years. The grant supports direct costs only; funds are not provided for indirect or overhead costs.

2. IAIMS Operational Phase

Health science institutions that complete the IAIMS planning phase successfully (or can demonstrate a comparably sophisticated information management plan based on their own planning efforts) may apply to NLM for an IAIMS operational phase grant to assist them in implementing the plan. Plans will vary for different institutions, but certain key elements are of interest to all:

A. Essential

- o A plan for developing the institution's information management resources, and the requisite networks;
--more-- Press [space] to continue, [q] to quit
- o A functional Information Management Policy;
- o Designation of leadership with appropriate background and status;
- o A plan for supporting IAIMS after termination of the grant;
- o Timetables for reaching key features of the operational plan;
- o Reasonable timetables for major plan features such as development of the network, organization of the management structure, appointment of the leadership, and post-grant financing plans. The ability of funded institutions to reach such milestones in a timely manner will be evaluated by the NLM when deciding annually on continuance of funding;
- o The ability to provide efficiently bibliographic and related literature pertinent to health care delivery and research. Significant participation by the health sciences library is essential; and
- o Substantial incorporation of one or more elements of HPCC/NREN into the institution's information system. Connection to Internet, for example, is one such element; other examples include collaboration through high speed networks, distance learning, addressing of computationally intensive problems in molecular biology in a distributed environment, visualization techniques, and network-based
--more-- Press [space] to continue, [q] to quit

B. Highly Recommended

- o A clear relationship to clinical aspects of the health sciences, such as linkage with a computerized patient record, a hospital information system, clinical alert information/distribution systems, clinically relevant expert systems, and/or systems for monitoring quality of care and cost-control; and
- o Incorporation of current NLM objectives such as, connection to

national networks, direct access to Medline and/or extensive use of Grateful Med, outreach components which improve information access for health care workers in underserved rural or inner city locations, and in other health care sites affiliated with the applicant.

C. Optional

o An apprenticeship in IAIMS may be incorporated into the operational plan at the discretion of the applicant, through a position entitled --more-- Press [space] to continue, [q] to quit IAIMS Assistant. An educational program should be described, outlining the credentials of the candidates, the goals and duration of the apprenticeship, the structure of the learning experience, and other relevant material. Personnel, travel and supply costs may be requested up to a total of \$50,000 for each year of the operational phase. Costs for apprentices should be budgeted in accordance with standard institutional policy.

Other Information About the Operational Grant

The operational phase grant application may include an initial period of model development at the discretion of the institution, but a distinct interim period of model-building is not required.

Operational phase grants may be for up to \$500,000 per year for five years, or for up to \$550,000 per year for five years if support for the apprenticeship program is included. Only direct costs are supported.

NLM support for IAIMS at an institution will terminate at the end of the five-year operational phase, and is not renewable.

--more-- Press [space] to continue, [q] to quit

The word "institution" as used in this program description implies that IAIMS will involve all major organizational components of the institution to the extent feasible. The NLM realizes that large differences among medical centers are inevitable, and that at some sites, certain suborganizations may not be suitable for incorporation into the initial IAIMS plan. However, a plan that is restricted to a relatively small fraction of the institution has misunderstood the point of the program, and will not be favorably reviewed.

APPLICATION PROCEDURES

Applicants are to use the PHS 398 (rev.9/91) application form, that includes forms, instructions and additional information, available at most academic medical centers, the Extramural Programs office, NLM, at the address listed under INQUIRIES, and from the Office of Grants Inquiries, Division of Research Grants, National Institutes of Health, Westwood Building, Room 449, Bethesda, MD 20892, telephone 301/496-7441. Applications must be received by the standard NIH deadlines, October 1, February 1, and June 1. Late submissions will be held over

--more-- Press [space] to continue, [q] to quit for the subsequent review cycle.
The title and number of this announcement must be typed in item 2a on the face page of the application.

The completed original application and five legible copies must be sent or delivered to:

Division of Research Grants
National Institutes of Health
Westwood Building, Room 2450
Bethesda, MD 20892**

REVIEW PROCEDURES

Applications will be assigned on the basis of established PHS referral guidelines. Applications will be reviewed for scientific and technical merit by the NLM Biomedical Library Review Committee, in accordance with the standard NIH peer review procedures. Following scientific-technical review, the application will receive a second-level review by the NLM Board of Regents.
--more-- Press [space] to continue, [q] to quit
Critical Review Elements

For Planning Phase:

- o Responsiveness to the program description and guidelines;
- o Institutional environment;
- o Extent of involvement by key leadership; and
- o Short and long-term goals.

For Operational Phase:

- o Responsiveness to the program description and guidelines;
- o Institutional commitment to the IAIMS concept, including evidence of significant cost-sharing;
- o Plans for support of IAIMS after the granting period; and
- o Sophistication and feasibility of the operational plan.

AWARD CRITERIA

--more-- Press [space] to continue, [q] to quit Applications will compete for available funding with all other applications assigned to the NLM. The following will be considered in making funding decisions:

- o Quality of the proposed project as determined by peer review;
- o Availability of funds; and
- o Program balance considerations.

INQUIRIES

Written and telephone inquiries are encouraged. The opportunity to clarify any issues or questions from potential applicants is welcome.

AUTHORITY AND REGULATIONS

This program is described in the Catalog of Federal Domestic Assistance No. 93.879. Awards are made under authorization of the PHS Act, Title III, Part A, Section 301, Title IV, Part D, Subpart 2, Sections 472-476, as amended, Public Law 100-607. This program is not subject to the intergovernmental review requirements of Executive Order 12372 or Health Systems Agency review.

--more-- Press [space] to continue, [q] to quit THE REQUEST FOR APPLICATIONS (RFA) ANNOUNCED IN THIS NOTICE CONTAINS

--more-- Press [space] to continue, [q] to quit ESSENTIAL INFORMATION FOR THE PREPARATION OF AN APPLICATION. POTENTIAL APPLICANTS MAY OBTAIN THE RFA FROM THE CONTACT NAMED IN INQUIRIES, BELOW.

PURPOSE

The National Institute on Deafness and Other Communication Disorders (NIDCD) invites applications for assistance awards to support cooperative multi-center (consortium) studies of the sensitivity, specificity, and predictive efficiency of methods to identify neonatal (birth to three months) hearing impairment. The major purpose of this request is to increase, through consortium arrangements, the extent and depth of research leading to the development of timely and efficient methods of identification of neonatal hearing impairment.

HEALTHY PEOPLE 2000

The Public Health Service (PHS) is committed to achieving the health promotion and disease prevention objectives of "Healthy People 2000," a PHS-led national activity for setting priority areas. This RFA, --more-- Press [space] to continue, [q] to quit Development of a Model System for Identifying Neonatal Hearing Impairment, is related to the priority area of maternal and infant health. Potential applicants may obtain a copy of "Healthy People 2000" (Full Report: Stock No. 017-001-11474-0) or "Healthy People 2000" (Summary Report: Stock No. 017-001-11473-1) through the Superintendent of Documents, Government Printing Office, Washington, DC 20402-9325 (telephone 202-783-3238).

ELIGIBILITY REQUIREMENTS

Any of the following organizations are eligible to apply: foreign and domestic non-profit and for-profit organizations and institutions, state and local governments and their agencies, and authorized Federal agencies.

MECHANISM OF SUPPORT

The support mechanism for this consortium project will be a cooperative clinical research grant (R10). This RFA is a one-time solicitation. Funding in response to this RFA is dependent upon the receipt of --more-- Press [space] to continue, [q] to quit applications of high scientific merit. The earliest start date for the initial awards will be April 1, 1993.

FUNDS AVAILABLE

Awards will be made for project periods of five years. Up to \$5 million total (direct plus indirect) costs is available for the entire project period of five years, or about \$1 million per year total for all awards. The NIDCD anticipates making one or two awards, but the specific amount and number of awards will depend on the merit and scope of the applications received. Budget increments after the first year will be limited to approved programmatic changes or to necessary cost-of-living increases. Although this project is provided for in the financial plans of the NIDCD, the award of grants pursuant to the RFA is contingent on the availability of funds appropriated for fiscal year 1993.

RESEARCH OBJECTIVES

The goal of this RFA is to support the conduct of coordinated --more-- Press [space] to continue, [q] to quit multicenter studies (consortium arrangements), leading to the development of a system for identification of neonatal hearing

impairment. Areas of research appropriate to the RFA may include, but are not limited to: screening normal and at-risk neonates with both auditory brainstem response (ABR) and otoacoustic emission (OAE) recordings; determining optimum stimulus and recording parameters for OAE; assessing the influence of co-existing medical factors on characteristics of ABR and OAE; assessing development related changes in OAEs that may occur particularly during the first year; establishing monaural threshold sensitivity for pure tones and speech; evaluating sensitivity, specificity, and predictive efficiency of ABR and OAE test methods, singly and in combination; and evaluation of time and cost-efficiency of the procedures. The goals of this RFA can be met by including the above areas of research in an application encompassing three project phases: screening, follow-up, and data analysis. A pilot or start-up phase of up to four months may also be included. Emphasis should be placed on the existing and potential strengths of the applicant organization related to the fulfillment and completion of the objectives of this RFA. Appropriate areas should include, but are not limited to: arrangements for biostatistical and/or epidemiologic --more-- Press [space] to continue, [q] to quit support, collaborations for ensuring availability of patients, arrangements for patient accrual, arrangements for coordination among cooperating institutions, identification of essential personnel for recruitment, and development of plans for acquiring or providing any special research skills needed.

STUDY POPULATIONS

SPECIAL INSTRUCTIONS FOR INCLUSION OF WOMEN AND MINORITIES IN CLINICAL RESEARCH STUDIES

For projects involving clinical research, NIH requires applicants to give special attention to the inclusion of women and minorities in study populations. If women or minorities are not included in the study populations for clinical studies, a specific justification for this exclusion must be provided. Applications without such documentation will not be accepted for review.

LETTER OF INTENT

--more-- Press [space] to continue, [q] to quit Prospective applicants are asked to submit, by June 31, 1992, a letter of intent that includes a descriptive title of the proposed project, the name and address of the Principal Investigator, the names of other key personnel and collaborating institutions, and the number and title of the RFA in response to which the application is being submitted. Although a letter of intent is not required, is not binding, and does not enter into the review of subsequent applications, submission of such a document allows NIDCD review staff to estimate the potential review workload and to avoid possible conflict of interest in the review.

The letter of intent is to be sent to:

Amy Donahue, Ph.D.
Chief, Hearing Program
Division of Communication Sciences and Disorders
National Institute on Deafness and Other Communication Disorders
Executive Plaza South, Suite 400B
6120 Executive Boulevard
Rockville, MD 20892
--more-- Press [space] to continue, [q] to quit Telephone: (301) 402-3458
FAX: (301) 402-6251

APPLICATION PROCEDURES

Applications are to be submitted on form PHS 398 (rev. 9/91) using the instructions included in the application kit. These kits are available from most institutional offices of sponsored research, the NIDCD Program Administrator cited below, and the Division of Research Grants, National Institutes of Health, Westwood Building, Room 449, Bethesda, MD 20892, telephone 301/496-7441. On page 1 of form PHS 398, check "yes" in item 2a and type: RFA DC-92-01: Development of a Model System for the Identification of Neonatal Hearing Impairment.

Complete applications are due no later than August 21, 1992, and must address all requirements in the RFA.

Applicants from institutions that have a General Clinical Research Center (GCRC) funded by the NIH National Center for Research Resources may wish to identify the GCRC as a resource for conducting the proposed --more-- Press [space] to continue, [q] to quit research. In such a case, a letter of agreement from either the GCRC program director or Principal Investigator must be included with the application.

REVIEW CONSIDERATIONS

Applications will be evaluated by NIDCD program staff to determine responsiveness to the RFA. Responsive applications will then be evaluated for scientific and technical merit by a review committee convened by the Scientific Review Branch of the NIDCD solely for this purpose. A second level review will be conducted by the National Deafness and Other Communication Disorders Advisory Council. Applications that are judged non-responsive will be administratively withdrawn, and the proposed Principal Investigator and institutional business official will be notified. Should an application be judged non-responsive to this RFA, any of its constituent projects may be submitted as an investigator-initiated individual research grant (R01) at the next receipt date or later. The new application would not be considered a response to an RFA.

--more-- Press [space] to continue, [q] to quit Factors considered to be important for review include demonstrated expertise in pediatric audiology, identification audiometry, neonatology, biostatistics and physiologic methods of hearing assessment; documentation of availability of an appropriate patient population; documented plans for interaction among collaborating institutions and clinicians; administrative support by the hospitals, clinics, or medical centers for all phases of the studies; and adequate facilities and ancillary personnel.

Reviewers will review the grant applications by considering the following criteria:

- o Appropriateness, originality, feasibility, and relevance of the proposed project to the overall goals and objectives of the RFA.

- o Qualifications, experience and proposed responsibilities of the Principal Investigators and key personnel.

- o Scientific merit and organizational plans for implementing the proposed program.

--more-- Press [space] to continue, [q] to quit

- o Demonstration of availability of normal and at-risk patient populations.

- o Proposed collaborations among audiologists, otolaryngologists, neonatologists, nursing staff, and other key personnel within the applicant and collaborating institutions; adequacy of documented interest, capabilities, and commitment of all potential participating clinics.

- o Facilities and resources, and the availability of such for this project.

- o Adequacy of proposed overall administrative procedures and inter- and intra-institutional collaborative arrangements.

- o Reasonableness and appropriate justification of the proposed budget.

- o Plans to protect the rights and welfare of human subjects, including appropriate informed consent procedures.

--more-- Press [space] to continue, [q] to quit

AWARD CRITERIA

The anticipated date of award is April 1, 1993.

In addition to technical merit, award decisions will be based on the responsiveness to RFA, the availability of resources, and the adequacy of the study populations.

Written and telephone inquiries concerning this RFA are encouraged. The opportunity to clarify any issues or questions from potential applicants is welcome. Direct inquiries regarding programmatic issues to:

assessment of feasibility

ACADEMIC AMERICAN

ENCYCLOPEDIA*p+50Y*p0X *p+51Y*p0XGENE*p+50Y*p0X *p+50Y*p0XThe gene is the unit of HEREDITY. Along with many other such*p+50Y*p0Xunits, it is transmitted from parents to offspring. Each gene, *p+50Y*p0Xacting either alone or with genes, determines one or more*p+50Y*p0Xcharacteristics of the resulting organism. The totality of*p+50Y*p0Xgenes that make up the heredity constitution of an organism is*p+50Y*p0Xcalled a GENOME.*p+50Y*p0X *p+50Y*p0XGenes occur in strands of genetic material called chromosomes*p+51Y*p0X(see GENETICS). In most cells each gene occupies a particular*p+50Y*p0Xposition within a specific chromosome.

Chromosomes can break,*p+50Y*p0Xhowever, and some of their genes may be transferred either to*p+50Y*p0Xplaces on the same chromosome or to other chromosomes. When*p+50Y*p0Xthis happens, new combinations (recombinants) of the gene are*p+50Y*p0Xformed. Genes can also change in chemical composition.

In*p+50Y*p0Xtheir altered recombinant or chemically varied form, they*p+50Y*p0Xproduce different elements from the unaltered genes (see*p+50Y*p0XMUTATION). Depending on the characteristics transmitted by the *p+50Y*p0Xgene, the environment may also play an important role

in*p+51Y*p0Xdetermining the extent to which the gene's potential effect is*p+50Y*p0Xrealized (see GENE BANK).*p+50Y*p0X *p+50Y*p0XTHE NATURE OF THE GENE*p+50Y*p0X *p+50Y*p0XThe subdivision of genetics concerned with the structure and*p+50Y*p0Xfunctioning of genes at the molecular level is called molecular *p+50Y*p0Xgenetics. Since the term gene was first proposed by the Danish *p+50Y*p0Xgeneticist Wilhelm Johannsen in 1909, concepts of the nature of *p+50Y*p0Xthe gene have undergone modification. Current understanding of *p+51Y*p0Xgene structure and function at the molecular level had its*p+50Y*p0Xorigin in 1944, with the work of Canadian bacteriologist Oswald *p+50Y*p0XT. AVERY and American scientist Colin M. MACLEOD and Maclyn*p+50Y*p0XMcCARTY. They showed that the genes of bacteria are composed*p+50Y*p0Xof the chemical compound called deoxyribonucleic acid, or DNA.*p+50Y*p0XThis was later found to be true of the genes of most other*p+50Y*p0Xorganisms.*p+50Y*p0XA further advance was made in 1953, when American biochemist*p+50Y*p0XJames D. WATSON and English scientist Francis CRICK jointly*p+50Y*p0Xpresented their model of the structure of the DNA molecule.*p+51Y*p0XThe molecule was shown to consist of two chains of chemical*p+50Y*p0Xcompounds called polynucleotides, the chains between twisted*p+50Y*p0Xinto the form of a coil, or double helix. Subsequently, in*p+50Y*p0X1961, U. S. biochemist M. W. NIRENBERG and others figured*p+50Y*p0Xout the relationship between the composition of DNA and the*p+50Y*p0Xcomposition of the proteins produced by genes.

This*p+50Y*p0Xrelationship is known as the GENETIC CODE. It later became*p+50Y*p0X *p+50Y*p0X *p+50Y*p0XCopyright (c) 1994 Grolier Electronic Publishing, Inc. All rights reserved.▲

ACADEMIC AMERICAN ENCYCLOPEDIA*p+50Y*p0X

*p+51Y*p0XGENE*p+50Y*p0X *p+50Y*p0Xevident that another nucleic acid, called ribonucleic acid, or*p+50Y*p0XRNA, also functions to carry out protein synthesis.*p+50Y*p0X *p+50Y*p0XAt first it was thought that all genes functioned in an*p+50Y*p0Xidentical manner to produce the various characteristics of

an organism. Three different classes of genes, however, are now recognized. One class consists of the structural genes, whose genetic codes determine the sequences of AMINO ACIDS that go to make up proteins or the smaller molecules known as polypeptides (see PEPTIDE), including many hormones. Another class of genes has genetic codes that specify molecules that function in the physical and chemical processes involved in PROTEIN SYNTHESIS. The third gene class consists of regulatory genes, which are noncoding. They act solely as "recognition" sites for enzymes and other proteins involved in controlling protein synthesis (see OPERON). Early studies seemed to indicate that a gene, wherever it happened to be located within a chromosome, consisted of a single continuous unit. Later it was found some genes have a region called the leader that precedes the coding segment, and a region called the trailer that follows it. In addition, the coding segment itself may actually be broken up into sections, with intervening coding portions called exons. A far-reaching advance in gene study was made in 1973, when American geneticists Stanley Cohen and Herbert Boyer demonstrated that certain enzymes, called restriction endonucleases, could be used to make cuts in a DNA molecule at certain specific sites. This produced a series of segments with identical free ends, which could join with other free ends having the appropriate complementary configuration. The result was the reestablishment of a fully functional DNA double helix. Using this procedure, called gene splicing (see GENETIC ENGINEERING), it became possible to take a gene from a human cell and transfer it to a bacterium, mouse, rat, or pig, where the human gene would function as it would in a human being. It even became possible to transfer animal genes to plants. One projected use of this procedure would be to transfer appropriate normal human genes to cells of individuals suffering from hemophilia, cystic fibrosis, or other GENETIC DISEASES. Should such transfers provide successful, they could provide a means to cure such genetic diseases through direct gene therapy.

PRODIGY(R) interactive personal service 03/10/94 10:14
 PM ACADEMIC AMERICAN ENCYCLOPEDIA
 GENE The actual functioning of genes is complex. To understand it, the nature and structure of the nucleus acids DNA and RNA must be examined in greater detail. DNA occurs as the genetic material in most viruses and in all cellular organisms. Some viruses, however, have no DNA. Instead, their genetic material is in the form of RNA. Depending on the particular DNA-containing organisms, most DNA is found either in a single chromosome, as in bacteria, blue-green algae, and DNA viruses, or in several chromosomes, as in all other living

things. In addition to its presence in chromosomes, DNA is also found in many CELL organelles, such as plasmids in bacteria, chloroplasts in plants, and mitochondria in both plants and animals. Structure All DNA molecules consist of a linked series of units that are called nucleotides. Each DNA nucleotide is composed of three subunits: a 5-carbon sugar called deoxyribose, a phosphate group that is joined to one end of the sugar molecule, and one of several different nitrogen-containing bases linked to the opposite end of the sugar molecule. The four bases that predominate in DNA are called adenine and guanine (double-ringed PURINE compounds), and thymine and cytosine (single-ringed PYRIMIDINE compounds). Four different types of DNA nucleotides can be formed, depending on the base involved. The phosphate group of each nucleotide bonds to one of the carbon atoms of the sugar molecule in the adjacent nucleotide. This forms a so-called polynucleotide chain. The DNA of most organisms consists of two polynucleotide chains that are coiled to form a double helix. The backbone, or outside margin, of each chain consists of the sugar-phosphate sequence. The bases project inward from this backbone, into the helix. The bases of one chain are attracted to bases on the other chain by means of hydrogen bonds. This holds the double helix together. Exceptions to this type of structural organization are found in some viruses with genetic material consisting of a single DNA chain. In a DNA double helix the pairing between bases of the two chains is highly specific. Copyright (c) 1994 Grolier Electronic Publishing, Inc. All rights reserved.▲

PRODIGY(R) interactive personal service 03/10/94 10:14
 PM ACADEMIC AMERICAN ENCYCLOPEDIA
 GENE chains is highly specific. That is, adenine is always linked to thymine by two hydrogen bonds, and guanine is always linked to cytosine by three hydrogen bonds. This arrangement--a purine linked to a pyrimidine--results in a molecule of uniform diameter. Because of this specific way in which DNA nucleotides are paired through certain pairs of bases, the base sequence of the two strands in the helix is said to be complementary. This means that the base sequence of either strand may be converted to that of its partner by replacing adenine by thymine or thymine by adenine, and replacing guanine by cytosine or cytosine by guanine. Functions The genetic material DNA has two specific functions. It provides for protein synthesis and hence for the growth and development of an organism. It also furnishes all descendants of the organism with protein-synthesizing information by replicating itself and passing a copy to each offspring. This information, known as the genetic code, lies in the sequence of bases of DNA, which specifies the sequence of amino acids in a protein. DNA does not act directly in the process of protein synthesis. Instead it acts through the formation of a particular type of RNA called the messenger RNA (mRNA)

during the process of transcription. DNA replication depends on the principle of complementarity mentioned above. During the process of replication, the two strands of DNA double helix separate from one another. As separation occurs, each base on each strand attracts its complementary base-containing nucleotide, to which it becomes attached by hydrogen bonds. For example, the base adenine attracts and bonds to the base thymine. As the complementary nucleotides are fitted into place, an enzyme called DNA polymerase performs its function. It binds the phosphate of one nucleotide to the sugar molecule of the adjacent nucleotide, forming a new polynucleotide chain. The new strand of DNA remains hydrogen-bonded to the old one, and together they form a new double-helix molecule. This type of replication is called semiconservative, because each newly formed double-stranded molecule consists of one previously existing DNA strand. Viruses, which contain single-stranded DNA, replicate by a slightly more complicated process. When a virus enters a cell, it

(c) 1994 Grolier Electronic Publishing, Inc. All rights reserved.▲

PRODIGY(R) interactive personal service 03/10/94 10:14
 PM ACADEMIC AMERICAN ENCYCLOPEDIA

GENE it makes a complementary copy of itself, to which it remains attached. A virus in this condition is said to be in its replicative form (RF), temporarily becoming a double-stranded DNA virus. The two chains separate during replication, but only the one recently formed strand attracts complementary nucleotides. These newly attracted nucleotides are joined together by the enzyme DNA polymerase, their base sequence being exactly the same as that of the original DNA virus. The newly formed polynucleotide chain is released from the RF of the original virus and functions alone.

Mutations Many environmental factors can alter the structure of a DNA molecule. Some factors may be physical, and others are chemical. A mutation occurs when such alterations lead to permanent change in the base sequence of a DNA molecule. Mutations in turn result in an inherited change in protein synthesis. Most mutations tend to be harmful in their effects, and a number of self-repair mechanisms exist to deal with the damage done to DNA by environmental factors. Processes of mutation and self-repair have been studied, for example, in the case of damage caused to DNA by exposure to ultraviolet (UV) light. The energy absorbed by DNA during UV exposure results in the formation of chemical bonds between adjacent bases of the same polynucleotide strand. This condition interferes with base pairing during replication and leads to mutations.

RNA Ribonucleic acid, or RNA, is needed in all organisms in order for protein synthesis to occur. It is also the genetic material of some viruses, which are referred to as RNA viruses (see VIRUS). Like DNA, all RNA molecules

have a similar chemical organization consisting of nucleotides. Each RNA nucleotide, like those in DNA, consists of three subunits. One is a 5-carbon sugar called ribose, the second is a phosphate group that is attached to one end of the sugar molecule, and the third is one of several different nitrogen-containing bases linked to the opposite end of the sugar molecule. Four bases predominate in RNA: adenine and guanine (double-ringed purine compounds), and uracil and cytosine (single-ringed pyrimidine compounds).

PRODIGO(R) interactive personal service 03/10/94 10:14
 PM ACADEMIC AMERICAN ENCYCLOPEDIA
 GENE Structure RNA differs from DNA in two aspects of its chemical organization. First, the sugar in RNA is of the ribose type, indicating that the second carbon molecule in the ring has a hydroxyl (OH) group attached to it. (In DNA the second carbon in the ring has only a hydrogen (H) atom--hence the prefix deoxy, meaning "lacking oxygen," in the DNA sugar deoxyribose.) Second, the base uracil is present only in RNA. (Thymine, the base comparable to uracil, is present only in DNA.) Both bases are single-ringed pyrimidines, and their nucleotides substitute for one another, depending on whether the strand is RNA or DNA. The nucleotides of RNA are joined in a polynucleotide chain by means of bonding the phosphate of each nucleotide to a carbon atom of the adjacent nucleotide's sugar subunit. In RNA viruses the RNA is in the form of either a double or a single polynucleotide chain. In double-stranded RNA versus, the geometric arrangement of the two polynucleotide chains is similar to that of double-stranded DNA, and the pairing between bases of the two RNA chains is highly specific. Adenine is always linked to cytosine by three hydrogen bonds. Again as in DNA, the specific pairing of RNA nucleotides according to the base concerned indicates that the base sequence of the two RNA strands is complementary. Thus if the base sequence of one strand is known, then the base sequence of the other strand can be specified. Functions Replication of double-stranded RNA follows the pattern described for DNA. The RNA chains separate, and each base attracts an RNA nucleotide carrying the complementary base, to which it is attached by hydrogen bonds. As the complementary nucleotides are fitted into place, an enzyme called RNA replicase binds the nucleotides together, forming a new polynucleotide chain. The new strand of RNA remains hydrogen-bonded to the old strand--another example of semiconservative replication. Single-strand RNA viruses fall into two classes. The first group includes the polio virus that attacks the nerve cells of humans and other primates. When this type of virus enters a cell, the virus makes a complementary copy of itself, to which it remains attached. In this stage the virus is again said to

*p+87YPRODIGY(R) interactive personal service 03/10/94 10:15
PM*p+50Y*p0X *p+50Y*p0X ACADEMIC AMERICAN ENCYCLOPEDIA*p+50Y*p0X
*p+51Y*p0XGENE*p+50Y*p0X *p+50Y*p0X5 percent of a cell's RNA.*p+50Y*p0X *p
+50Y*p0XThe third type of cellular RNA, messenger RNA, constitutes 5 to *p

+50Y 10 percent of a cell's total RNA. It acts as an intermediary between the genes located in the chromosomes, and the ribosomes located in the cytoplasm. As its name implies, mRNA carries the genetic code contained in the sequence of bases in the cell's DNA. Because the DNAs from various organisms differ only in the sequence of their bases, mRNA from different organisms must reflect this difference in base sequence. The synthesis of mRNA, called transcription, involves the formation of an RNA chain that is complementary to one of the two strands of a DNA double helix. In the transcription process, only nucleotides that contain ribose are used. In this process, uracil acts as the complement of adenine. The enzyme involved in transcription is known as RNA polymerase. RNA as an Information Molecule The earliest information molecule to have evolved must have been both relatively simple in structure and capable of enzymatic activity. RNA, which acts as the carrier of genetic messages in all organisms, is the simplest molecule known that has the capacity to store and transmit information. Initially, evidence that RNA can also act as a catalyst of reactions centered on the enzyme called ribonuclease P, which consists of protein and RNA. The enzyme has been found on virtually all organisms. It is involved in the process that transforms the precursor molecules of tRNAs into their fully functional forms. Geneticists have since discovered that the RNA component of this enzyme, acting alone, can perform the catalytic activity of the enzyme, whereas the protein alone cannot. More recently, investigations have concentrated on the ribosomal-RNA specifying gene of the protozoan Tetrahymena thermophila. This gene consists of a noncoding sequence, or intron, between two coding portions, or exons. After transcription, the precursor RNA molecule has to have the intron-transcribed segment removed before the ribosomal-RNA molecule can become functional. The intron specified segment snips itself out of the precursor molecule and splices the loose ends together to form the functional molecule. These findings, that RNA is capable of catalytic activity, lend support to the concept that RNA was indeed the earliest information molecule. Copyright (c) 1994 Grolier Electronic Publishing, Inc. I. Introduction

Genetic epidemiology is increasingly focused on the study of common diseases with both genetic and environmental determinants. The concept of gene-environment interaction is becoming a central theme in epidemiologic studies that assess causes of human disease in populations (1). Advances in genetic technology and the work of the Human Genome Project will make it easier for the study of gene-environment interaction to become an integral part of epidemiologic research. In this paper, we review epidemiologic concepts and definitions applied to gene-environment interaction and give an overview of both traditional and emerging approaches in epidemiologic studies of human disease.

II. Concepts and Measurement of Interaction in Epidem

A. [Evolving epidemiologic concepts and definitions of interaction](#)

Over the last two decades, there has been much discussion about how to define and measure interaction in epidemiologic studies (2-12). Much of this discussion focused on deriving the expression for the relative risk for disease associated with exposure to

multiple factors when the joint effects of these factors act through the same pathogenetic pathway. The interaction of two or more risk factors can be measured as a departure from a multiplicative model of disease risk (27). Using such an approach, it is relatively easy to find parsimonious models by keeping statistical interactions to a minimum (10).

However, it is not clear what ultimately constitutes interaction or synergy on the biological level, and that any statistical approach is inherently arbitrary and model-dependent (7-8, 12).

Interaction can also be measured in terms of a departure from an additive model of disease risk (8). In this model, at an individual level, a causal interaction effect can be understood by a hypothetical contrast of the outcome of a single subject under different exposure conditions to develop a disease. For example, assuming two dichotomous risk factors (A and B) of a disease, a person might develop the disease at age 70 if exposed to A only, at age 60 if exposed to B only, and at age of 50 if exposed to both risk factors. The advance from 60 years of age to 50 years of age is due largely to the joint interacting effects of factors A and B. At the population level, if two factors can cause a disease, some cases of disease will involve exposure to both risk factors. In the absence of either factor, these cases would not occur (12). Several measurements and their confidence intervals were developed to measure the departure from an additive model: relative excess risk due to interaction, and attributable proportion due to interaction (8, 13-14). Measuring interaction as departure from additivity is also useful in assessing the public health implications in diseases prevention and in individual decision making in considering exposure to certain risk factors, such as smoking and alcohol (15).

B. Gene-environment interaction

There is accumulating evidence that allelic variations of many gene loci may play important roles in determining individual susceptibility to cancer (16-20) and other chronic diseases (21-23). In assessing the role of susceptibility alleles in disease risk, one should consider the effects of gene-environment interaction in disease etiology. Gene-environment interaction may be measured by the different effect of an exposure on disease risk among individuals with different genotypes or by the different effect of a genotype on disease risk among individuals with different exposures (24-25).

The concept of gene-environment interaction has long been recognized by geneticists (26), and occupied an essential place in ecogenetic studies which examine genetically determined differences among individuals in their susceptibility to environmental risk factors (27-29). In recent years, an epidemiologic framework for evaluating gene-environment interaction has been proposed (24, 30-32). In a simple gene-environment interaction model, in which both the susceptibility genotype at a single locus and the environment exposure are considered dichotomous, one can construct an extended 2-by-2 table incorporating genetic and environment factors in studying disease etiology (24).

Table 1 shows a simple gene-environment interaction model in the context of epidemiologic studies. For this simple model, it is assumed that unexposed individuals without the susceptibility genotype have a certain background risk for disease I. R_e refers to the relative risk for disease among people without the susceptibility genotype for disease who are exposed to the environmental risk factor relative to those with neither the susceptibility genotype nor exposure. R_g refers to the relative risk among people with the susceptibility genotype who are not exposed to the environmental risk factor relative to those with neither the susceptibility genotype nor exposure. R_{ge} is the ratio of disease risk

among exposed people with susceptibility genotype to disease risk among unexposed people without the susceptibility genotype. This ratio reflects the strength of the gene-environment interaction.

Based on this simple gene-environment interaction model, the effects of six biologically plausible patterns of interaction on the relative risk of disease has been proposed (24)(Table 2). In type 1 interaction, the increased risk of diseases was only observed when both genetic and environmental factors coparticipate in the same pathogenetic mechanism, neither the genotype alone nor the exposure alone causes excess risk (i.e., $R_g = R_e = 1$). In type 2 interaction, environmental exposure increases risk in individual without the corresponding genotype. In type 3 interaction, the genotype ($R_g > 1$) is associated with increased disease risk, whereas the exposure alone is not. In type 4 interaction, both the genotype and the environmental exposure are each associated with excess risk of disease ($R_g > 1$, $R_e > 1$). Type 5 and 6 interaction occur when there is a reversal of the genotype's effect, depending on the presence or absence of the environment. In this case, the genotype is protective in the absence of the environment ($R_g < 1$), but is deleterious in the presence of the environment ($R_{ge} > 1$). Ottman (31) also proposed a similar model of studying gene-environment interaction in etiology of disease. In any gene-environment interaction model, the effects of gene-environment interaction on the measured phenotype are further complicated by the number of genetic loci involved and multiple environmental exposure factors, the moderation of the genetic effects, the dose of the environmental exposure, and the presence of etiologic heterogeneity (24, 31). Most studies have evaluated gene-environment interaction in terms of the departure from that predicted by the multiplicative model (33-34). Some investigators have suggested that many biologically plausible modes of gene-environment interaction involve extreme departures from multiplicative effects (35). For example, neither phenylalanine hydroxylase deficiency alone nor exposure to phenylalanine in the diet cause phenylketonuria (PKU); both must be present for PKU to develop (24). The gene-environment interaction may also be evaluated in terms of the departure from those predicted by the additive model.

III. Gene-Environment Interaction in Traditional Epidemiologic Studies

A. Strategies

The main emphasis of gene-environment interaction studies is not to localize the disease susceptibility genes or to find the inheritance patterns of the diseases, but rather to better understand the etiology and pathogenesis of the diseases through quantitative assessment of diseases risks in various populations (24, 31-32, 36-37).

Two types of genetic markers are used in gene-environment interaction studies: markers based on direct analysis of the DNA, and markers based on gene products such as specific blood groups, HLA antigens, serum proteins, and enzyme systems. When genetic markers are not available, family history data are sometimes used as a rough indicator of genetic susceptibility, though there is a potential for significant misclassification in using family history data in genetic epidemiologic studies (38-39).

Although the number of genetic polymorphisms available for research will increase markedly in the near future, studies of gene-environment interactions will be most meaningful when applied to functionally significant variations in candidate genes which

have a clear biological relation to or suspected of playing some role in the pathogenesis of disease (40-41).

B. Study design

Gene-environment interaction can be analyzed through the use of the traditional epidemiologic study design: cohort, cross-sectional, and case-control studies.

When a relatively high number of polymorphic markers are located close to candidate gene loci, the case-control approach is a popular and effective means by which to study differences in genetic susceptibility and gene-environment interaction (24, 33). In a case-control design, the genetic markers and relevant environmental risk factors are each examined as independent predictors of disease and as interacting factors. The odds ratio of gene-environment interaction (R_{ge}) can be calculated as shown in Table 1. Examples of recent case-control studies include a study of interaction effects between maternal cigarette smoking and a transforming growth factor alpha (TGFA) polymorphism and the risk of oral clefts (42). The odds ratios for the exposure to smoking alone, and for the TGFA genotype alone are close to unity, whereas the combined odds ratio for smoking and the genotype is 5.5 (95% C.I. 2.1-14.6), indicating evidence of gene-environment interaction for risk of oral clefts in offspring (42).

In a cohort study design, the environmental exposures and genetic risk factors are measured for all subjects at the start of follow-up (baseline) and possibly during follow-up. Despite major strengths of cohort study design (disease occurs or is detected after subjects are selected, minimizing selection bias), few cohort studies used genetic markers to test for effects of gene-environment interaction in disease etiology. This is partly because the rapid development of molecular techniques have been seen only recently and the main stream of genetic analysis has been to locate disease susceptibility genes. With the advances in molecular techniques and the findings of more candidate genes, one would expect to see increasing number of cohort studies to examine gene-environment interaction. Also, case-control studies nested in cohort studies will be increasingly used. In cross-sectional design, the investigators study individuals from a study population through a single ascertainment of disease prevalence. Individuals with different genetic and environment risk characteristics are compared with respect to the prevalence of the condition, and gene-environment interaction can also be tested (24). An example is the cross-sectional WHO-cardiac study of gene-environment in hypertension, stroke and atherosclerosis (43). Although cross-sectional designs are less time-consuming and able to examine many exposures and disease in the same study, an important limitation of cross-sectional is the inability to separate the effects of any genotype as a cause of the disease compared with its effect on duration and/or survival associated with the disease. A number of case-control studies are including a familial component, such as a family history of the disease under study. The designs and some problems of the case-control studies incorporating family history are discussed in the epidemiologic literature (1, 34, 44) and by contributors to this special volume. The study of familial aggregation in case-control studies can be extended by incorporating environmental covariates and their interaction with family history (45).

C. Methodologic Issues in assessing gene-environment interaction

Mis-specification

In the presence of gene-environment interaction, quantifying the main effects of environmental factor alone or genetic factor alone can lead to mis-specification of the

study model, and under some situation lead to missing the effects of each factor in the the etiology of the disease (46).

Misclassification of environmental exposures

Precise measurement of an individual's exposure to environmental risk factors is often difficult because of the individual's ignorance or poor recall of previous exposures, the complex pattern of most long-term exposures, and the lack of good biological indicators of exposure levels (45). In the study of gene-environment interaction, the consequences of environmental exposure mismeasurement can lead to bias in the estimation of relative risks associated with interaction effects and possible loss of precision and power with which interaction effects are estimated (24). Nondifferential misclassification usually leads to biases of relative risk toward the null value, and differential misclassification may produce biased relative risks in either direction. In addition to the errors of environmental exposure measurement, the timing of exposure during a developmentally important window can also be important in examining gene-environment interaction. For example, the timing of the exposure to an environmental agent during the pregnancy and the development of a birth defect for a genetically susceptible fetus may be critical.

Misclassification of genotype

When measuring individuals' genotypes at the DNA level, misclassification can occur because of linkage disequilibrium (24, 47). Investigators usually rely on genetic markers in the region of the candidate genes or in a nonexpressed portion of the genes in order to conduct many DNA marker-disease association studies. Under these circumstances, the observed differences in prevalence of a marker allele between case and comparison groups could be a result of linkage disequilibrium unless the actual sites of a deleterious variation involved in the disease are targeted (24, 48-49). Under linkage disequilibrium, Nondifferential misclassification can occur, and this misclassification may bias estimates of relative risk of the genotype toward the null (i.e. $OR = 1$). Individual genotypes can also be measured by indirect methods. For example, some investigators used dapsone loading followed by urinary measurements of different metabolites to classify subjects as slow or fast acetylators in a case-control study of bladder cancer (50-51). Such indirect measures can lead to misclassification of the underlying genotypes of individuals. This type of misclassification is often independent and nondifferential. However, the argument that independent and nondifferential measurement errors produced bias only toward the null may not apply to assessments of gene-environment interaction. As with all types of interactions, independent and nondifferential misclassification may bias interaction estimates in any direction (12). Occasionally, genotype misclassification may be differential if the measurement method is affected by disease status itself or if a near-by gene is associated with the disease; such differential misclassification will further complicate the assessment of gene-environment interaction (1).

Confounding

Confounding is a major problem in studying genetic factors and evaluating gene-environment interaction. It can involve population subgroups with different genetic markers and disease frequencies. Unmeasured genetic determinants and environmental exposures can each act as confounders that could produce spurious associations. Race or ethnicity is an important source of confounding in studies of genetic factors (52). One

example is the reported association between the genetic marker Gm3;5;13;14 and non-insulin-dependent diabetes mellitus among the Pima Indians (53). In a cross-sectional study of this association, individuals with the genetic marker Gm3;5;13;14 were found to have a higher prevalence ratio of the disease than those without the marker (29% vs.8%). This marker, however, turned out to be an index of white admixture. When the subjects of the analysis were stratified by degree of admixture, the higher prevalence of diabetes associated with the marker disappeared.

Dose-response relationships

In traditional epidemiologic studies, dose-response relations refer to the changes in risk produced by changes in a single exposure, and interaction refers to changes in risk produced by two or more exposures. The interplay between dose-response relationships and interaction is complex (54). In assessments of the effect of gene-environment interaction on disease risk, the risk in disease associated with a certain genotype may vary depending on the environmental exposure, or the risk may be restricted to exposed persons only. Similarly, the effects of environmental exposures may vary depending on the genotype of the exposed person (25). For example, people who are slow acetylators of N-acetyltransferase 2 (NAT2) have an increased risk for bladder cancer, and the risk for bladder cancer associated with smoking may vary by NAT2 status (55). For slow acetylators of NAT2, current smoking and smoking in the distant past increased breast cancer risk in a dose-dependent manner. Those in the highest quartile (heavy smokers in the study) of cigarettes smoked 2 years previously were 4.4 (95% CI, 1.3-14.8) times more likely to develop breast cancer than those who never smoked (56).

Sample size considerations

In an epidemiologic study of a given sample size, the power to detect statistical interactions is less than the power to detect main effects, and the variance of the interaction estimate will also be greater than the variance of the main effects estimate under a no-interaction model (7, 57-58). Several investigators have examined the sample size and power calculation needed to detect gene-environment interaction in case-control studies (59-61). The data needed to calculate the sample size required to detect gene-environment interaction can be shown by a 2-by-4 table as is done in Table 3. This table lists six parameters: 1) The odds ratio of interaction (R_{ge}); 2) The odds ratio of having the disease among exposed individuals without the susceptible genotype relative to those with neither the susceptibility genotype nor exposure (R_e); 3) the odds ratio of having the disease among people with susceptible genotype but without environmental exposure relative to those with neither the susceptibility genotype nor exposure (R_g); 4) the prevalence of exposure in the population (e); 5) the prevalence of the genotype in the population (g); 6) the case/control ratio (59-60). The results of several studies have suggested that when the frequency of exposure is not extremely low or high, and the susceptible genotype is common, a modest sample size will be adequate to detect gene-environment interaction. For example, when the frequency of exposure and the prevalence of the genotype both range between 30% to 70%, about 200 case subjects and 400 control subjects (for case/control ratio 1:2) should be adequate to detect an R_{ge} greater than 4 with 80% statistical power (60). However, the susceptible genotypes for many common diseases are relatively rare, with prevalence ranging from 1 to 5%, and both the genotype alone (R_g) and exposure alone (R_e) have moderate effects on risk for

disease. For example, for a genotype that is relatively frequent in the population (e.g., the 185delAG mutation in the BRCA1 gene occurs in about 1% of Ashkenazi Jews) (62), and for many risk factors for common disease having odds ratios around 2 (e.g., breast cancer risk factors (63)), a relatively large number of case and control subjects are needed to detect gene-environment interaction (usually more than 1,000 cases)(60). Increasingly, alternative approaches to detecting gene-environment interaction are being developed. These approaches, briefly reviewed in the next section, include 2-tier sampling strategies (64-65), family or sibling-based designs (61), and case-only designs (66).

IV. Gene-environment Interaction in Nontraditional Epidemiologic Studies

Concerns about selecting appropriate control subjects for case-control studies have led to the development of several nontraditional approaches in the study of genetic factors in disease (1, 34). These approaches involve the use of an internal control group rather than an external one. We will review three of these nontraditional approaches in detecting gene-environment interaction: 1) the case-only study, 2) the case-parental control study, and 3) the affected relative-pair study. Except for the case-only design, these nontraditional approaches were not developed with the intention of evaluating gene-environment interaction. Table 4 summarizes the features of these studies, including their assumptions, strengths, and limitations. We also briefly review use of the twin study to evaluate gene-environment interaction.

A. Case-only studies

The case-only design has been promoted as an efficient and valid approach to screening for gene-environment interaction under the assumption of independence between exposure and genotype in the population (67-68). If one's primary interest is in assessing possible interaction between genetic and environmental factors in the etiology of a disease, one may do so without employing control subjects. The basic set up for a case-only design is a 2-by-2 table (Table 5). The odds ratio calculated from a case-only design is related to the odds ratios for the exposure alone, the genotype alone, and their joint effects in the case-control design by the following formula:

$$OR_{ca} = R_{ge}/(R_e * R_g) * OR_{co},$$

where OR_{ca} is the case-only odds ratio, and OR_{co} is the odds ratio among control subjects relating the exposure and the susceptibility genotype. Assuming independence between the genotype and the exposure in the population, the expected value of OR_{co} becomes unity, and the odds ratio obtained from a case-only study measures the departure from the multiplicative joint effect of the genotype and the exposure. Under the null hypothesis, $OR_{ca} = 1$; $OR_{ca} > 1$ if the joint effect is more than multiplicative; and $OR_{ca} < 1$ if the joint effect is less than multiplicative (e.g., additive) (34). Confidence intervals of case-only odds ratio can be obtained by using standard crude analyses or logistic models that control for the effects of other covariates.

Table 6 shows data from a case-control study of the association between cleft palate, maternal smoking and TGFA polymorphism derived from Hwang et al. (42). The case-only OR_{ca} of 5.1 (95% CI, 1.5-18.5) calculated from Hwang et al. (42) can be compared with the odds ratio of the interaction 5.5 (95% CI 2.1-14.6) derived from their case-control study. Both odds ratios suggest a significant interaction between TGFA polymorphism and maternal smoking in the risk for cleft palate among the offspring.

Study has shown that the case-only design requires fewer case subjects than case-control design to detect gene-environment interaction (66).

In applying the case-only design to test gene-environment interaction, investigators assume independence of the distribution of exposure and genotype in the population. This assumption may seem reasonable for a wide variety of genes and exposures, but there are some genes whose presence may be associated with a higher or lower likelihood of the exposure on the basis of some biologic mechanisms (34). The gene-environment interaction (OR_{ca}) derived from a case-only design assumes a departure from multiplicative effects. Studies have shown that many biologically plausible modes of gene-environment interaction involve a departure from multiplicative effects (35). If the true underlying model of joint effect is additive, the odds ratio of interaction (OR_{ca}) derived from a case-only design is questionable.

B. Case-parental control studies

The case-parental design may be an effective method of dealing with the effects of confounding by hidden population stratification (e.g. due to ethnicity; 69-71). In addition, when disease alleles are common and have modest effects, an association study may provide a more sensitive test for linkage between genetic markers and disease susceptibility genes than the classical linkage analysis (41). Several methods (72-77) combine the advantages of linkage and population association analyses and also take into account the effect of confounding. All these methods consider the alleles found in the parents of an affected offspring and compare transmitted and untransmitted alleles of parents to the affected offspring (transmission/disequilibrium test). Investigators using these methods can compare the genotype of the affected offspring with the genotype of a fictitious control subject carrying the nontransmitted alleles from each parent. The 2-by-2 tables used in such a comparison are shown in Table 7. Odds ratios can be calculated in an analysis following that of a matched-pair design (34). To test gene-environment interaction, investigators can stratify case subjects according to their environmental exposure status (presence or absence) and can assess for homogeneity in odds ratios derived with and without the environmental exposure as an indication of departure from multiplicative interaction (34).

One limitation of this method could be that the "control" group may not be representative of the underlying population at risk, especially when certain parental genotypes associated with disease status may interfere with reproduction. In other study (78), investigators proposed using a noniterative method, which compares risk among those with a specific genotype with the risk among those with a comparison genotype. To study gene-environment interaction, investigators can stratify on the environmental factor to obtain stratum-specific estimates of the disease-gene association, and the difference in the stratum-specific estimates reflect gene-environment interaction (78).

The need for the parents of the case subjects to be genotyped is another limitation of case-parental approach. The parental marker data may not be available for some case subjects, especially in studies of the genetic etiology of diseases with older age at onset. In other studies (79), investigators developed a method using marker information on all members of a nuclear family to infer the probability distribution of missing parental marker data.

C. Affected relative-pair studies

The third type of nontraditional epidemiologic method that can be used to test gene-environment interaction is the affected sib-pair or affected relative-pair method (80-84). In sib-pair analysis, investigators determine whether each sib-pair shares 0, 1, or 2 alleles identical by descent (IBD) at a locus of interest. Under random segregation, the expected distribution of sharing 0, 1, or 2 alleles is 25%-50%-25% between two siblings IBD. Departure from this distribution suggests linkage between the disease and the marker locus (84).

In contrast to the case-only and case-parental approaches, the sib-pair method is primarily used to test for genetic linkage when the genetic model underlying the disease is not known, especially for common disease involving multiple etiologies (1). The sib-pair methods can be incorporated into family-based epidemiologic studies (cohort and case-control designs): such incorporation allows investigators to control for suspected nongenetic risk factors and to test for gene-environment interaction in searching for genetic linkage (85-86). To look for gene-environment interaction using this method, investigators can stratify the affected individuals by their exposure status or incorporate the gene-environment interaction term in a multivariate analysis. For example, they can use logistic regression when testing for genetic linkage (86-87). The basic set-up for analyzing gene-environment interaction through sib-pair analysis is shown in Table 8. The difference of odds ratios for diseases between exposed and unexposed individuals are taken as an indication of gene-environment interaction.

The sib-pair method requires families with at least one affected member in addition to the proband. This requirement restricts the number of families for which this analytic method can be used. Because the affected relative-pair approach assumes Mendelian transmissions for expected distributions, any departure from independent segregation and random assortment could affect the results. Finally, selection factors, including survival, chronicity, and method of case ascertainment, may substantially affect the types of case subjects that could be available for this analysis (78, 86).

D. Twin studies in gene-environment interaction

The premise behind twin studies is that, because monozygotic twins (MZ) have 100% of their genes in common whereas dizygotic twins (DZ) have only 50% of their genes in common, an excess disease concordance among MZ twins may reflect a greater role of genetic factors. Several investigators have extended the classical twin study to test for gene-environment interaction (25, 88-89). For example, Ottman (25) developed a method to test for gene-environment interaction on disease risk conditional on twin exposure status and genotype. This method involved two measures of relative risk: 1) relative risk for disease among exposed vs. unexposed cotwins, stratified by zygosity and proband exposure status (RR_e), and 2) relative risk for disease among MZ vs DZ cotwins, stratified by exposure status of the proband and cotwin (RR_z). Ottman then examined the behavior of the two measures under different assumptions about the relative effect of exposure and genotype on disease. RR_e reflects the effect of exposure on disease risk. When gene-environment interaction is present, RR_e is expected to differ between MZ and DZ twins because of their different probabilities of having the high risk genotype. RR_z reflects the effect of genotype on disease risk. When gene-environment interaction is present, RR_z is expected to differ between exposed and unexposed twins. In another study, investigators used a case-control design to calculate the odds ratios for disease among affected vs unaffected cotwins and compared these odds ratios among the various

strata defined by exposure in the index twin. Gene-environment interaction is indicated by the difference in odds ratios by stratified environmental exposures (89). Recently, other investigators extended the twin study method by including the half-siblings in a study of genetic and environmental factors in the etiology of disease (90). Given the possible confounding by shared environmental factors (intrauterine and postnatal) and selection factors, the effects of gene-environment interaction obtained from twin studies should be interpreted with caution (1).

ACADEMIC AMERICAN ENCYCLOPEDIA*p+50Y*p0X

*p+51Y*p0XGENETICS*p+50Y*p0X *p+50Y*p0Xbear only one factor for each characteristic; (5) hereditary*p+50Y*p0Xfactors for different traits sort independently of one another*p+50Y*p0Xat gamete formation (law of independent assortment); and (6)*p+50Y*p0Xgametes join randomly, irrespective of the factors

that they carry. The characteristic that appeared in the first generation plants--in this case, tall plants--seemed to dominate over the one that did not appear. Mendel called tallness a dominant trait and shortness recessive; this phenomenon was referred to as the law of dominance. A capital A is now usually used to represent the gene that determines the dominant character, and a small a for one that determines the recessive character. When a pair of hereditary factors, or genes, are of the same type (AA), the condition is said to be homozygous for that character. On the other hand, if the two members of a pair are different (Aa), the condition is called heterozygous. The second generation plants of Mendel's experiment were composed of one-quarter AA, one-half Aa, and one-quarter aa. Since tallness is dominant, AA and Aa both appear tall, accounting for the three-quarter: one-quarter ratio of tall to short. The alternate forms of a gene, known as alleles, combine to produce different genetic types, or genotypes. Mendel demonstrated that the three-quarter: one quarter ratio existed for all seven characteristics of peas that he studied; he also showed that the separate gene pairs behaved independently of each other during gamete formation. CHROMOSOMES Mendel's knowledge of genes and their behavior was entirely theoretical. Subsequent studies of CELL structure and cell division have supplied physical evidence supporting his theories. It is now generally believed that genes behave as they do because of their location on chromosomes (see GENETIC CODE), structures found in the nucleus of each CELL of an organism. Chromosomes are not all the same length, and, when stained in the appropriate way, each may show characteristic bands, thickenings, or constrictions. The cells of each species contain a fixed and characteristic number of chromosomes. Some organisms, such as fungi and single-celled algae, have only a single set, or haploid number (n), of chromosomes in their cell nuclei. The somatic cells of a

 PM ACADEMIC AMERICAN ENCYCLOPEDIA
 GENETICS most higher organisms, including humans, contain two sets, or a diploid number (2n), of chromosomes. Still other organisms, such as mosses, ferns, and horsetails, alternate between diploid and haploid during different stages of their life cycles. Meiosis In diploid cells, gene pairs are located at specific sites (loci) on each chromosome. These gene pairs can be composed either of two identical genes or two alleles. A diploid cell therefore contains two genes for each hereditary characteristic. The gametes (sex cells) of diploid organisms, however, contain only a haploid (n) number of chromosomes; the union of two gametes, one from each parent, produces a

diploid (2n) zygote, from which the offspring develops. The process of cell division by which such gametes are produced is called meiosis. It takes place in the testes and ovaries of animals, in the anthers and ovaries of higher plants, and in the sporophyte (2n) stage of organisms that alternate between haploid and diploid. In meiosis a single diploid cell divides into two diploid cells, each of which divides into two haploid cells. During this process, the two sets of chromosomes separate, thereby separating the members of the gene pairs. Each of the four resulting gametes therefore contains only one gene for each characteristic, and different gametes from the same parent may carry different alleles. Mendel's postulates may therefore be restated in physical terms as follows: (1) genes are located on chromosomes; (2) genes occur in pairs, occupying specific loci on a chromosome pair; (3) the first meiotic division separates the chromosome pairs, producing an equal division of the members of a gene pair in the product cells; (4) since there are two cell divisions and only one replication of chromosomes, the chromosome number is halved; (5) different gene pairs on separate chromosome pairs behave independently of each other; and (6) collision of egg and sperm is a chance process. Linkage and Crossing-Over In the early 1900s, Thomas Hunt MORGAN used the fruit fly *Drosophila melanogaster* to test a situation that Mendel did not encounter, in which two gene pairs are located on the same chromosome. PRODIGY(R) interactive personal service 03/10/94 10:11
 PM ACADEMIC AMERICAN ENCYCLOPEDIA
 GENETICS chromosome pair. In this case they do not behave independently, since genes on the same chromosome tend to stay together during meiosis. This is called linkage. The combinations can be separated by the simultaneous breaking of homologous chromosomes during the first meiotic division, and the joining of the broken segments from each chromosome to the homologous broken segments. This process, called crossing-over, occurs regularly during meiosis and randomly between any chromosome pair in a bundle of four. Crossovers can be detected genetically if they involve two heterozygous gene pairs (the alleles producing distinct gene products). Under a microscope, they appear as cross-shaped structures called chiasmata. Mapping Crossing-over can be used to produce a chromosome map showing the relative positions of the loci of the known gene pairs. Two organisms having homozygous gene pairs are bred, and the offspring (first generation) has heterozygous gene pairs (AaBb). This heterozygote is then crossed with a tester strain of the genotype aabb, a standard tool known as a testcross. The progeny of a testcross are screened for the appearance of the genotype Aabb and aaBb, which can only arise from crossovers. The frequency of these types is a standard measure of

+50Y]p0Xand is assumed to be proportional to the distance between the]p+50Y]p0Xtwo loci on their chromosome. Using different combinations of]p+50Y]p0Xgene pairs, an internally self-consistent map can be]p+51Y]p0Xconstructed in which the number of map units is defined as the]p+50Y]p0Xpercentage of progeny in a testcross derived from a crossover.]p+50Y]p0X]p+50Y]p0XThe Role of Chromosomes]p+50Y]p0X]p+50Y]p0XIt is now known that genes are lengths of a threadlike chemical]p+50Y]p0Xcalled deoxyribonucleic acid (DNA) and form a continuous string]p+50Y]p0Xthat constitutes the chromosomes. Several researchers have]p+50Y]p0Xattempted to explain the significance of the long assemblages]p+50Y]p0Xof genes in chains, or chromosomes. First, some combinations]p+51Y]p0Xof genes have adaptive value and need to be inherited as a]p+50Y]p0Xpackage. Having them linked closely on one chromosome is one]p+50Y]p0Xway of ensuring this. Second, genes with related functions]p+50Y]p0Xoften need to be activated simultaneously; their proximity]p+50Y]p0Xallows them to be activated by one common switch mechanism.]p+50Y]p0XThird, the packaging of genes into units facilitates the]p+50Y]p0Xorderly production of daughter cells in cell division.]p+50Y]p0X]p+50Y]p0X]p+50Y]p0XCopyright (c) 1994 Grolier Electronic Publishing, Inc. All rights reserved.▲

]p+87YPRODIGY(R) interactive personal service 03/10/94 10:11
PM]p+50Y]p0X]p+50Y]p0X ACADEMIC AMERICAN ENCYCLOPEDIA]p+50Y]p0X
]p+51Y]p0XGENETICS]p+50Y]p0X]p+50Y]p0XCrossing-over and independent assortment of genes result in]p+50Y]p0Xcombinations of genes in progeny that are different from the]p+50Y]p0Xparental arrangements. This process, called recombination, is]p+50Y]p0Xbelieved to be an important mechanism for generating new]p+50Y]p0Xgenotypes. Recombination most frequently occurs among genes]p+50Y]p0Xwidely separated from each other; closely linked genes,]p+50Y]p0Xhowever, have a random chance of rearrangement.]p+50Y]p0X]p+51Y]p0XPOLYGENES AND GENE-ENVIRONMENT INTERACTION]p+50Y]p0X]p+50Y]p0XMendel explained the phenomenon of discontinuous hereditary]p+50Y]p0Xvariation, which is expressed in separate and distinct forms]p+50Y]p0Xthat are associated with one kind of allele, such as tall]p+50Y]p0Xversus short or wrinkled versus smooth. Continuous variations]p+50Y]p0Xoccur in many phenotypes, however, such as length or weight, is]p+50Y]p0Xalso commonly observed in nature and forms an apparently]p+50Y]p0Xunbroken range from one extreme to another. This phenomenon,]p+50Y]p0Xknown as polygenic inheritance, results from the complex]p+51Y]p0Xinteraction among a set of genes. Human skin color, shades]p+50Y]p0Xranging from black through brown and yellow to white, is a good]p+50Y]p0Xexample of a trait determined by polygenes. Only an infinite]p+50Y]p0Xnumber of polygenes, however, could give a perfectly continuous]p+50Y]p0Xvariation.]p+50Y]p0X]p+50Y]p0XThe phenotype of an organism is shaped not only by its genotype]p+50Y]p0Xbut also by the interaction of that genotype with the]p+50Y]p0Xenvironment. It is often difficult to determine the relative]p+50Y]p0Xcontribution of genetic and environmental variation to a]p+51Y]p0Xparticular phenotype.]p+50Y]p0X]p+50Y]p0XSEX DETERMINATION]p+50Y]p0X]p+50Y]p0XThe sex of an organism is usually an inherited phenotype. In]p+50Y]p0Xhaploid forms, alleles of one gene pair can determine sex, but]p+50Y]p0Xin higher organisms sex is often associated with a special pair]p+50Y]p0Xof chromosomes called sex chromosomes. For example, human]p+50Y]p0Xcells

contain 22 pairs of autosomes, or nonsex chromosomes, and one pair of sex chromosomes. Women possess two identical sex chromosomes (X and X), and men possess two different sex chromosomes (X and Y). The presence or absence of the Y chromosome determines sex in humans; therefore, the Y contains the genes for male sex determination, called the "testis-determining factor" (tdf). In many higher plants, anthers and ovaries are located on separate plants (dioecism), and some of these have an X/Y-like chromosomal determination of sex. PRODIGY(R) interactive personal service 03/10/94 10:11
PM ACADEMIC AMERICAN ENCYCLOPEDIA
GENETICS In humans, the X chromosome bears genes that affect traits having nothing to do with the sex. Because they are located on the X, however, they show a special inheritance pattern different from autosomal gene inheritance; the Y chromosome apparently has no counterpart to these genes. Red-green color blindness and hemophilia are two genetic traits determined by X-linked genes. The X and the Y genes are able to separate into equal numbers of sperm in the male and produce a 1:1 ratio of males to females in the eggs that they fertilize. THE NATURE OF THE GENE The genetic material for most organisms, DNA, is a double-stranded helix comprising a long chain of nucleotide bases with a sugar-phosphate backbone, as proposed by James D. WATSON and Francis H. C. CRICK in 1953. Eukaryotic cells contain two kinds of DNA sequences: unique DNA, one copy present in a haploid gene set; and repetitive DNA, identical copies (one million or more) found dispersed throughout the chromosome. The unique segments probably contain regular genes. The function of repetitive DNA segments is not known, although they may be involved either in the process of chromosome pairing or in regulating the activity of the unique sequence. DNA of eukaryotic organisms appears to be wound around nucleosomes--small, beadlike units that each consist of about 200 base pairs of DNA and a complex structure of proteins known as histones. Nucleosomes help package the DNA into the chromosome--an average human chromosome is about 0.005 mm in length and contains 50 mm of DNA. During mitotic cell division chromosomal replication produces two identical daughter cells, each of which contains identical DNA, assuring the stability of the hereditary material. The DNA replication is semiconservative. This means that free nucleotides hydrogen-bond to each half of the separate DNA strands, resulting in two new DNA double helices each consisting of one-half old and one-half newly formed strands. Genes of the DNA in eukaryotic organisms (RNA in some viruses) control phenotype by coding for the structure of PROTEINS, which are the main structural and catalytic molecules in an organism; hair, muscle, skin, tendons, and enzymes are all proteinaceous. The order of the nucleotide bases in

DNA dictates the corresponding order of amino acids that give rise to a particular protein. Copyright (c) 1994 Grolier Electronic Publishing, Inc. All rights reserved.▲

PRODIGY(R) interactive personal service 03/10/94 10:12
PM ACADEMIC AMERICAN ENCYCLOPEDIA
GENETICS proteins their specific shape and function during PROTEIN SYNTHESIS. The protein-building information in DNA is copied into a single-stranded molecule, called messenger RNA (mRNA), that then moves to the cytoplasm, where protein synthesis occurs. The nucleotides in mRNA can be thought of as letters that are read in groups of three, called codons, each codon standing for an amino acid. The amino acids are transported to the mRNA by transfer RNA molecules, and the protein is assembled on the surface of ribosomes. In humans the DNA in each cell contains about 3 billion base pairs, distributed among 22 sets of autosomal chromosomes and one set of sex chromosomes in the nucleus as well as one set of chromosomes in each mitochondrion. If all of this DNA were stretched out, it would have a length of about 1 m (3 ft), but the DNA is tightly compressed into the chromosome. Only about 2 percent of a person's DNA forms the actual genes, as well; the rest constitutes either noncoding "spacer" regions between genes or noncoding "intron" regions within genes. The amount of DNA per cell varies tremendously within both animal and plant kingdoms and is unrelated to the taxonomic group concerned (see GENETIC CODE; GENOME). MUTATION is the process by which genes change from one form to another. Mutations may be caused by such mutagens as X rays, ultraviolet rays, nitrous acid, ethyl methane sulfonate, and nitrosoguanidine; less frequently, mutations may occur spontaneously as a result of accidental changes in the chemistry of the cell. Because mutation is random, haphazard change, most mutants contain damaged genes that are nonfunctional. Mutants usually do not live long in nature; geneticists and breeders, however, may keep mutants alive for study or for use in producing new plant and animal forms in agriculture. A mutation in DNA usually results in an altered nucleotide sequence, either by substitution, addition, deletion, or insertion, which is translated into an altered amino-acid sequence that usually produces a change in the organism's normal body function. The alteration of amino acids can have a drastic effect on function, as in the case of sickle-cell hemoglobin. A mutation of the chromosome by transposition, translocation, or insertion can cause similar effects. Mutations of cells other than sex cells are considered to be asexual. PRODIGY(R) interactive personal service 03/10/94 10:12
PM ACADEMIC AMERICAN ENCYCLOPEDIA

GENETICS primary cause of cancer in those tissues. All humans carry quite a large number of deleterious and lethal mutant genes that are recessive. Each mating is a kind of a lottery, in which the offspring reveal whether or not the parents' mutations are at identical loci. For example, if both parents are heterozygous (Aa) for a gene pair in which the recessive allele is deleterious, then one-fourth of their children will show genetic disease of the kind controlled by that locus. Genetic counseling can often help prospective mates in determining whether such diseases will manifest in their offspring (see also GENETIC IMPRINTING).

GENES IN DEVELOPMENT Most organisms start life as single cells (zygotes) and grow into massive multicellular bodies with cells of considerable differences in form and function. This process, which involves growth and differentiation, is called DEVELOPMENT. Although skin cells, liver cells, brain cells, and so on, are highly differentiated, they are all derived from the original zygote as a result of the high-fidelity copying of DNA during mitotic division. This is achieved by a complex, little-understood process whereby different genes are active in different tissues. The best examples of gene regulation are found in bacteria, where genes of related function are grouped on the chromosome together with a special class of regulatory genes to form an operon, which is a kind of control unit. The operon theory was proposed by Francois Jacob and Jacques Monod in 1961. Regulatory genes, usually responding to environmental cues, either assist or prevent the passage of the mRNA synthesis enzyme, RNA polymerase, along the operon, thereby controlling gene activity. No satisfactory examples of operons have been found at present in higher organisms, but several examples of regulatory genes are known, although these are not necessarily linked to a controlled locus. Repetitive DNA that is interspersed between unique DNA has been postulated as a site of a vast system of regulatory genes.

GENES IN CYTOPLASMIC ORGANELLES Although most genes are found in the chromosomes of the nucleus, two kinds of cytoplasmic organelles, mitochondria and chloroplasts, also contain certain genes. Phenotypes determined by these genes are inherited through the female parent. Maternal or uniparental inheritance has been extensively studied in microorganisms, notably the unicellular algae, chlamydomonas, and several fungi. In Chlamydomonas, a variety of drug-resistant and morphological phenotypes are involved. In fungi, sensitivity to certain drugs, such as erythromycin, paramomycin, and oligomycin, can be cytoplasmically inherited, as can some kinds of poor

 PM ACADEMIC AMERICAN ENCYCLOPEDIA

chloroplasts, also contain certain genes. Phenotypes determined by these genes are inherited through the female parent. Maternal or uniparental inheritance has been extensively studied in microorganisms, notably the unicellular algae, chlamydomonas, and several fungi. In Chlamydomonas, a variety of drug-resistant and morphological phenotypes are involved. In fungi, sensitivity to certain drugs, such as erythromycin, paramomycin, and oligomycin, can be cytoplasmically inherited, as can some kinds of poor

growth phenotypes ("petites" in yeast and "poky" in the bread mold *Neurospora*). The mitochondria and chloroplasts carry their own DNA, which is circular and unlike nuclear DNA in nucleotide composition. They also contain their own autonomous protein-synthesizing system, many parts of which are coded by organellar DNA genes. Many other components of the mitochondria and chloroplasts, such as cytochromes, are coded by genes of nuclear DNA. These organelles are therefore composed of a mixture of components with DNA blueprints located in both the nucleus and the organelle. The specific synthesizing machinery of mitochondrion, together with its shape and size, have suggested to some that the mitochondrion is a vestige of a primitive symbiotic association with bacteria. Similarly, the structure and functions of a chloroplast are reminiscent of the primitive blue-green algae. This kind of evolution, in which complexity results from the adoption of an internal collection of simpler cells, is called hereditary symbiosis and may have been important in the development of modern cells.

GENES IN POPULATIONS

Mendelian genetics can predict the inheritance patterns within families, but one should not expect to see similar patterns and ratios in populations, which are complex mixtures of different families. A different approach, sometimes called population genetics, is used to analyze genetic distribution in populations. Each locus contains two alleles (A and a) of one gene. The gene pool of a population is derived by considering each diploid individual to be one cell bearing two genes at that locus. The total number of A and a genes in a population is calculated and an allele frequency for each is obtained. Usually, the frequency of A is called p, and the frequency of a is called q. Copyright (c) 1994 Grolier Electronic Publishing, Inc. All rights reserved.▲

PRODIGY(R) interactive personal service 03/10/94 10:12
 PM ACADEMIC AMERICAN ENCYCLOPEDIA
 GENETICS is called q, where $p + q = 1$ (or 100%). The allele frequencies are the main determinants of the genetic structure of populations. If mating is random for example, there will be p^2 of AA, $2pq$ of Aa, and q^2 of aa. This genotype distribution, which is stable if all other factors are constant, is called Hardy-Weinberg equilibrium, named after its discoverers. At its most fundamental level, evolution is little more than a change in relative allele frequencies. The actual values of p and q at each locus are determined by the complex interaction of many forces, including mutation from A to a, mutation from a to A (reversion, which is usually less frequent than forward mutation), chance fluctuation due to small populations (producing genetic drift of allele frequencies), and natural selection for or against certain genotypes. In turn, selection can be directional, ultimately eliminating one allele from the population, or stabilizing, favoring intermediate genotypes and tending to maintain

several alleles and phenotypes in an interbreeding population, a phenomenon called genetic polymorphism. Preliminary results of a different form of genetic study of human evolution aroused controversy at the 1987 meeting of the American Anthropological Association. The research involved analyses of mitochondrial DNA in placental samples from women with a worldwide distribution of ancestry. Such DNA is inherited only from the mother, and through mutation studies the researchers hoped to trace human ancestry back to a "single" source--some generation of first humans. The results of a team of geneticists working at the University of California, Berkeley, suggested a human family tree with roots in sub-Saharan Africa some 140,000 to 200,000 years ago. Another team, at Emory University, proposed a common ancestor of similar age but in southeastern Asia. Anthropologists expressed considerable skepticism, however, about these results of what came to be known as the "Eve" hypothesis. Most anthropologists consider that the first true humans appeared much longer ago (see PREHISTORIC HUMANS). MODERN GENETICS Genetics is an important aspect of many areas of pure and applied biology.  PM ACADEMIC AMERICAN ENCYCLOPEDIA
 GENETICS Genetics, animal genetics, and human genetics focus research on specific types of organisms. Research in molecular genetics involves studies on chemical structure and function; cytogenetics on location of the genetic material in cells and on cell division; developmental genetics on the genetic function in embryological phenomena; behavior genetics on the role of the gene in regulating behavior; and population genetics on the evolutionary process. At the applied level, genetics is of direct use in understanding genetic diseases and environmental mutation. It is used in plant and animal breeding to improve the quality and quantity of food. It also is a tool in basic research by which complex biological processes can be analyzed, often at the molecular level. A. J. W. Griffiths

AB The number of Medicare-certified home health agencies nearly doubled from 1980 to 1990. Using **Health Care Financing** Administration data, this study documented national and regional patterns of entry and exist by Medicare home health providers from 1980 to 1990. Nationally, agency origination rates accelerated during the early 1980s and then dropped abruptly in the second half of the decade. The proprietary sector, accounting for approximately 42% of agencies in existence during the period of the study, exhibited the greatest volatility. Regional differences are also evident. Both expansion and contraction in Medicare home health services appear to be a response to the incentives of legislation implemented during this period.

AB OBJECTIVES. Health maintenance organizations (HMOs) with Medicare contracts often provide cancer screening and preventive services not covered under fee-for-service. This study compared cancer patients in HMOs and fee-for-service on stage at diagnosis. METHODS. The study examined stage at diagnosis for aged Medicare enrollees in HMOs and fee-for-service, using information from the Surveillance, Epidemiology, and End Results program, linked with Medicare enrollment files. Twelve cancer sites were investigated, and demographics, area of residence, year of diagnosis (1985 to 1989), and education at the census tract level were controlled. RESULTS. HMO enrollees were diagnosed at earlier stages for cancers of the female breast, cervix, colon, and melanomas and at later stages for stomach cancer. There were no differences for cancers of the prostate, rectum, buccal cavity and pharynx, bladder, uterus, kidney, and ovary. HMO effects were strongest in areas with large, mature HMOs. CONCLUSIONS. Compared with fee-for-service enrollees, HMO enrollees were diagnosed at earlier stages for cancer sites for which effective screening services are available. The earlier detection of certain cancers among HMO enrollees may result from coverage of screening services and, perhaps, promotion by HMOs of such services.

JT MMWR. MORBIDITY AND MORTALITY WEEKLY REPORT

LA Eng

AB Influenza is a major cause of debilitating illness and premature death in the United States, particularly among persons aged > or = 65 years and those with chronic conditions such as lung or heart disease, diabetes, and cancer. Medicare reimbursement for excess hospitalizations during influenza epidemics ranges from \$750 million to \$1 billion (1). In May 1993, influenza vaccination became a covered Medicare benefit after its potential cost-effectiveness was established by the Medicare Influenza Vaccine Demonstration (2). During the fall of 1993, the **Health Care Financing** Administration (HCFA) initiated an information campaign to promote use of the influenza vaccination benefit, implemented simplified billing procedures, and improved electronic billing capabilities. However, reports during the 1993-94 influenza season suggested problems experienced by state and local health departments in implementing the new benefit. To characterize public influenza vaccination programs and problems with implementing this benefit, in the spring of 1994, CDC collected information from all 63 state and local health departments receiving federal immunization grants. This report summarizes the reports from these programs.

 TI Detection and treatment of prostate cancer: perspective of the urologist
 [see comments]
 SO J Urol 1994 Nov;152(5 Pt 2):1695-9
 JT JOURNAL OF UROLOGY
 AD Department of Urology, Squier Urologic Clinic, Columbia College of
 Physicians and Surgeons, Columbia Presbyterian Medical Center, New York,
 New York.
 LA Eng
 AB We examine changes in the detection and treatment of prostate cancer
 from the perspective of the urologist. There has been an extraordinary
 increase in the incidence of prostate cancer (60% from 1990 to 1993).
 We calculated, based on data from the literature and assumptions about
 changes in urological practice, that 52% of newly diagnosed cases would
 be treated by radical prostatectomy in 1993. Extrapolating from the
 work of Catalona, we derived the number of office consultations,
 prostate biopsies and orchiectomies associated with the diagnosis and
 treatment of these tumors. Applying **Health Care Financing**
 Administration reimbursements to our figures, we calculated that each
 urologist would realize \$45,370 for prostate cancer care in the Medicare
 population in 1993. If all patients 50 to 70 years old were screened by
 American Cancer Society and American Urological Association recommended
 algorithms, this projection would be \$107,919. Despite this enormous
 economic impact of prostate cancer on the urologist, uncertainties
 remain concerning the appropriateness of screening and treatment for
 this disease. Only increased funding for basic research in prostate
 cancer will resolve these uncertainties.

TI The production of dialysis by for-profit versus not-for-profit
freestanding renal dialysis facilities.
SO Health Serv Res 1994 Oct;29(4):473-87
JT HEALTH SERVICES RESEARCH
AD Division of Internal Medicine, Johns Hopkins University School of
Medicine, Baltimore, MD 21205.
LA Eng
AB OBJECTIVE. A study was conducted to determine whether for-profit and
not-for-profit freestanding renal dialysis facilities differ with
respect to efficiency in the production of dialysis treatments. DATA
SOURCES/STUDY SETTING. National data on 1,224 Medicare-certified
freestanding dialysis facilities were obtained from the **Health Care
Financing** Administration's (HCFA) 1990 Independent Renal Dialysis
Facility Cost Report. Data on Medicare patients receiving care at these
facilities during 1990 were obtained from HCFA's End Stage Renal Disease
(ESRD) Program Management and Medical Information System (PMMIS). STUDY
DESIGN. Ordinary least squares regression (OLS) was used to estimate
the association between monthly output of dialysis treatments in 1990
and (a) facility capital and labor inputs, (b) facility ownership
characteristics, and (c) case-mix characteristics. DATA
COLLECTION/EXTRACTION METHODS. Facility and patient level data were
extracted from the Facility Cost Report and the PMMIS databases,
respectively. Patient level data were aggregated by facility and merged
with facility level data. PRINCIPAL FINDINGS. For-profit sole
proprietorships, for-profit partnerships and for-profit corporations
each produced significantly more dialysis treatments per month than
not-for-profits, adjusting for quantities of resource inputs and
case-mix characteristics. CONCLUSION. For-profit facilities appear to
be more efficient producers of dialysis treatments than not-for-profits.
Further study should address whether other factors such as differences
in severity of disease or in quality of care are responsible for these
observations.

TI Analysis of variations in mortality rates with small numbers.
SO Health Serv Res 1994 Oct;29(4):461-71
JT HEALTH SERVICES RESEARCH
AD Georgia Medical Care Foundation, Atlanta.
LA Eng
AB OBJECTIVE. We present a Monte Carlo technique to evaluate if observed mortality rates differ from model-predicted rates for situations when the number of deaths is small. DATA SOURCES. We used Medicare hospital claims and model-predicted mortality rates from the **Health Care Financing** Administration (HCFA) for the 169 acute care hospitals in Georgia. The HCFA data provided model-predicted mortality rates at 30 days postadmission for 17 conditions and procedures of interest. The model-predicted rates calculated by HCFA were adjusted for patient factors, including demographic characteristics, principal diagnosis, and comorbidities. STUDY DESIGN. We test the hypothesis that model-predicted 30-day mortality rates at the 169 hospitals differ significantly from the observed 30-day mortality rates. Our approach uses a test statistic that resembles a chi-square statistic, and Monte Carlo simulations to estimate the distribution of the test statistic under the null hypothesis of no differences between the observed and predicted rates. We illustrate the method using two conceptually similar simulation models. We use results of the simulations to estimate p-values and compare these results with p-values associated with the nominal chi-square distribution. DATA EXTRACTION METHODS. We extracted 30-day observed and predicted mortality rates for Medicare beneficiaries for federal fiscal year 1990 for 17 conditions and procedures of interest. PRINCIPAL FINDINGS. If the number of deaths in some hospitals is small, p-values calculated using the nominal chi-square distribution can be misleading, thus supporting the usefulness of our simulation method. CONCLUSIONS. The Monte Carlo simulation is an appropriate approach to the analysis of hospital mortality or small area analysis for situations in which the number of deaths is small.

 AB The growth of health services employment in the United States is
 modelled using ARIMA analysis, and related to the growth in total U.S.
 employment. It is argued that specific features of the medical care
 sector (licensed professional manpower, non-profit firms, third-party
 financing) create institutional rigidities which delay adjustment to
 macroeconomic conditions and other shocks. Tests of Granger causality
 and the pattern of coefficients in the cross-correlation function show
 that health services employment does lag other sectors of the economy by
 an average of 2 to 4 years. A Box-Jenkins transfer-noise function model
 between total and health employment is constructed and evaluated, and
 the impact dynamics of adjustment to Medicare and Medicaid are
 estimated.

 TI Severity of illness measures derived from the Uniform Clinical Data Set
 (UCDSS).
 SO Med Care 1994 Sep;32(9):881-901

JT MEDICAL CARE
AD Medical College of Wisconsin, Department of Family and Community
Medicine, Milwaukee 53226.
LA Eng
AB The ****Health Care Financing**** Administration (HCFA) plans to use the
Uniform Clinical Data Set System (UCDSS) to collect data on hospitalized
Medicare patients. This study examined the value of UCDSS data for
creating severity of illness measures. UCDSS data were obtained from a
study hospital and from a national data set for patients with pneumonia
(n = 528) and stroke (n = 565). Models to predict length of stay or an
adverse event were derived for each condition using HCFA claims data
alone, UCDSS data alone, and UCDSS data supplemented with additional
information also abstracted from charts. The models were derived from
one set of patients and validated on another. The R2 for predicting
length of stay in the validation data for the UCDSS model was 0.29 for
pneumonia and 0.19 for stroke compared to R2 values from the claims
model of 0.09 for stroke and 0.06 for pneumonia. UCDSS models also were
better than claims models for predicting adverse events. The best UCDSS
models included International Classification of Diseases, Ninth
Revision, Clinical Modification (ICD-9-CM) codes and other information
requiring clinical judgment, and were improved by adding more
information on patient functional status. Some findings were more
strongly associated with outcome for the study hospital than for the
national data. These results suggest that UCDSS models will predict
outcome much better than the claims based models currently used by HCFA
for the analysis of hospitalization-related mortality; more functional
status information should be added to UCDSS; and despite an extensive
objective database, the most predictive UCDSS models require
clinician-assigned diagnostic codes.

 TI Health care policies affecting the treatment of patients with cancer and cancer research.
 SO Cancer 1994 Oct 1;74(7 Suppl):2204-7
 JT CANCER
 AD Association of Community Cancer Centers, Rockville, MD 20852.
 LA Eng
 AB BACKGROUND. Reimbursement policies under the current **health care financing** system are chaotic, even for older individuals who might expect some measure of uniformity under federal statutes that govern coverage under Medicare. Policy changes at the federal level have increased the complexity and uncertainty of reimbursement for providers and patients. METHODS. The Association of Community Cancer Centers, in conjunction with a number of state medical oncology societies, distributed surveys to medical oncologists in 20 states during 1993. Eight hundred, fifty-six medical oncologists in 282 practices responded with information on their practices and insurance problems. RESULTS. Data illustrate the broad diversity of coverage for cancer treatment and research and its impact on treatment decisions and patient access. The broad spectrum of results from various states indicates significant differences in the implementation of federal policies on key issues, such as access to chemotherapeutic agents for off-label indications and clinical trials. CONCLUSIONS. The data portray the significant influence of insurance company policies on clinical research and disease prevention and treatment. Under the current system, prevention measures and prevention trials are discouraged, and a growing number of insurers are not paying for clinical research. New state and federal legislation offers some hope that uniformity of access to providers, prevention, off-label drugs, and clinical trials may be on the horizon.

 SO Salud Publica Mex 1994 Mar-Apr;36(2):129-39
 JT SALUD PUBLICA DE MEXICO
 AD Southwest Border Rural Health Research Center, College of Medicine,
 University of Arizona, Tucson 85716.
 LA Spa For
 AB Arizona physicians practicing in the four counties bordering Mexico were
 surveyed regarding the use of their services by residents of Mexico.
 One hundred eighty-eight (79%) of the 239 respondents to the mail survey
 reported seeing at least one Mexican resident per week during 1988.
 Ninety-nine of these physicians (53%) practiced in Tucson; 89 (47%)
 practiced elsewhere in the four border counties. The mean number of
 Mexican resident patients seen per week was nine (9% of total) for
 border physicians and 5 (6% of total) for Tucson physicians. The most
 frequent responses from border physicians asked to list the most common
 health conditions of their Mexican resident patients were injury and
 poisoning (21%) and circulatory diseases (11%), while the most frequent
 responses of Tucson physicians were circulatory diseases (10%) and
 digestive diseases (9%). Problems and solutions in the border care
 health system are mainly related to quality of care and **health care
 financing**.

 AB The variation in mortality rates among hospitals has often been described informally as having three major components: patient severity, quality of care and random variation. These informal concepts are characterized formally by partitioning sums of squares and finding their expected values. The partition relates to commonly used tests for whether individual hospitals have unusual mortality rates. Application of the partition to the hospital mortality reports by the **Health Care Financing** Administration shows that their models for patient risk account for about one-half the variation among hospital mortality rates. An example using clinical measures of severity accounts for about two-thirds of mortality variation among hospitals.

TI Using Medicaid claims data to evaluate a large physician fee increase.
SO Health Serv Res 1994 Aug;29(3):315-40
JT HEALTH SERVICES RESEARCH
AD Policy and Health Statistics Administration, Maryland Department of Health and Mental Hygiene, Baltimore, MD 21201.
LA Eng
AB OBJECTIVE. This study demonstrates the use of Medicaid claims data in order to evaluate a threefold fee increase in physician fees for deliveries (\$265 to \$795), which the Maryland Medicaid program implemented in 1986. DATA SOURCES AND STUDY SETTING. The study used Maryland Medicaid claims data for years of service 1985-1988, and was done at the Maryland Department of Health and Mental Hygiene with the help of a Robert Wood Johnson, **Health Care Financing** and Organization (HCFO) grant. STUDY DESIGN. Overall, our design is that of a pre-test, post-test with multiple observation points both before and after the fee increase. We measured participation in three ways, corresponding to three different units of analysis. With the county-quarter year as unit of analysis, we followed a panel of providers over 16 quarters for each county in the state to determine changes in the number of delivering providers. With the individual provider as the unit of analysis, we identified effects on their Medicaid caseload between years that may have been influenced by the fee increase. Finally, we looked at continuously enrolled Medicaid women who delivered to determine the effects of the fee increase on site and volume of prenatal care. DATA COLLECTION/EXTRACTION METHODS. Analytic files for each unit of analysis were compiled from previously extracted Medicaid claims files using standard statistical software packages. PRINCIPAL FINDINGS. Using techniques described, we were able to get an in-depth picture of overall responsiveness to the intervention. We found a moderate influence of the fee increase on overall participation, less than what we would have predicted. CONCLUSIONS. Administrative data can be used to construct efficient, yet sophisticated evaluations of major policy changes. Findings from our evaluation suggest a moderate effect of the fee increase on overall participation. However, raising fees to the level of private third party payers does not in itself guarantee equal access to private physician health care for Medicaid mothers.

- LA Eng
- AB STUDY QUESTION. Can the steady increases in health care expenditures as a share of GDP projected by widely cited actuarial models be rationalized by a macroeconomic model with sensible parameters and specification? DATA SOURCES. National Income and Product Accounts, and Social Security and **Health Care Financing** Administration are the data sources used in parameters estimates. STUDY DESIGN. Health care expenditures as a share of gross domestic product (GDP) are projected using two methodological approaches--actuarial and macroeconomic--and under various assumptions. The general equilibrium macroeconomic approach has the advantage of allowing an investigation of the causes of growth in the health care sector and its consequences for the overall economy. DATA COLLECTION METHODS. Simulations are used. PRINCIPAL FINDINGS. Both models unanimously project a continued increase in the ratio of health care expenditures to GDP. Under the most conservative assumptions, that is, robust economic growth, improved demographic trends, or a significant moderation in the rate of health care price inflation, the health care sector will consume more than a quarter of

national output by 2065. Under other (perhaps more realistic) assumptions, including a continuation of current trends, both approaches predict that health care expenditures will comprise between a third and a half of national output. In the macroeconomic model, the increasing use of capital goods in the health care sector explains the observed rise in relative prices. Moreover, this "capital deepening" implies that a relatively modest fraction of the labor force is employed in health care and that the rest of the economy is increasingly starved for capital, resulting in a declining standard of living.

AB OBJECTIVES. The purpose of this study was to compare lumbar spine surgical procedures by age, gender, and number of comorbidities with respect to mortality in patients 65 years of age and older in the United States. METHODS. A 100% sample of the 1986 Medicare inpatient **Health Care Financing** Administration claims files databases involving lumbar spine surgical procedures was analyzed. RESULTS. Lumbar spine surgery in 34,418 patients (median age = 71 years) was associated with a significant increase in in-hospital and 1-year cumulative mortality only beyond 80 years of age. When adjusted for age, in-hospital and 1-year

cumulative mortality with both decompression and excision procedures were significantly higher in men than in women. When adjusted for both age and gender, mortality increased significantly as the number of comorbidities increased. CONCLUSIONS. With lumbar spine surgery in elderly patients, mortality did not significantly increase until 80 years of age and was consistently associated with decompression and excision, with male gender, and with an increase in number of comorbidities.

AB OBJECTIVES. Dehydration has been underappreciated as a cause of hospitalization and increased hospital-associated mortality in older people. This study used national data to analyze the burden and outcomes following hospitalizations with dehydration in the elderly. METHODS. Data from 1991 Medicare files were used to calculate rates of hospitalization with dehydration, to examine demographic characteristics and concomitant diagnoses associated with dehydration, and to analyze the contribution of dehydration to mortality. RESULTS. In 1991, 6.7% (731,695) of Medicare hospitalizations had dehydration listed as one of the five reported diagnoses, a rate of 236.2/10,000 elderly Medicare beneficiaries. In 1991, Medicare reimbursed over \$446 million for hospitalizations with dehydration as the principal diagnosis. Older people, men, and Blacks had elevated risks for hospitalization with dehydration. Acute infections, such as pneumonia and urinary tract infections, were frequent concomitant diagnoses. About 50% of elderly Medicare beneficiaries hospitalized with dehydration died within a year of admission. CONCLUSIONS. Hospitalization of elderly people with dehydration is a serious and costly medical problem. Attention should be focused on understanding predisposing factors and devising strategies for prevention.

TI Geographic distribution of hospitalization rates, case fatality, and
mortality from stroke in the United States.
SO Neurology 1994 Aug;44(8):1541-50
JT NEUROLOGY
AD Department of Neurology, University of Kentucky, Lexington 40536-0084.
LA Eng
AB We analyzed state-specific stroke-hospitalization, case-fatality, and
mortality rates for the US Medicare population for 1989, using national
data resources of the **Health Care Financing** Administration (HCFA),
the National Center for Health Statistics, and the Bureau of the Census.
State-specific hospital admission rates for stroke ranged from 0.66 to
1.26%, compared with the national value of 0.94%. Both hospital-usage
rates and deviations of observed rates from predicted values (based on
statistical models of the HCFA) showed significant spatial
autocorrelation, with high rates clustered in the southeastern United
States and low rates clustered in the Mountain census division of the
West and also somewhat in the Northeast. Case-fatality rates increased
nationally from 14.9% at 15 days after hospital admission to 31.2% at
180 days after hospital admission. State-level case-fatality rates
showed relatively little interstate variation and no clear or consistent
spatial pattern, although there was statistically significant spatial
autocorrelation at several intervals after hospital admission.
Admission rates and case-fatality rates were not significantly
associated at any interval after admission to 180 days, suggesting that
variation in case-fatality rates was not simply a result of differences
in severity-of-illness thresholds for hospital admission.
State-specific stroke-mortality rates ranged from 294.5 to 523.5 per
100,000 population, compared with the national value of 415.3 per 100,
000 population. State-specific mortality rates for stroke showed
significant spatial autocorrelation, with high rates clustered in the
South and low rates clustered in the Northeast and the Mountain census
division of the West. The spatial distribution of stroke-mortality rates
strongly resembled the spatial distribution of hospitalization rates but
did not resemble the spatial distribution of case-fatality rates at any
interval from 15 to 180 days after hospital admission. Indeed, in
univariate spatial-regression models fitted to the data using a maximum
likelihood procedure and weighted for non-constant variances, the best
predictor of state-level stroke-mortality rates was the
hospital-utilization rate for stroke; attempts to improve the model by
including case fatality at various intervals and interaction terms did
not yield a significant improvement. These data suggest that factors
determining stroke occurrence and hospital utilization are more
important than factors determining case fatality in terms of explaining
the long-standing distribution of stroke mortality in the United States.
Factors affecting only case fatality but not hospitalization, such as
the quality of medical care provided in the hospital, cannot explain the
geographic distribution of stroke mortality in the United States.

TI The use of **Health Care Financing** Administration data for the development of a quality improvement project on the treatment of anemia.
SO Am J Kidney Dis 1994 Aug;24(2):247-54
JT AMERICAN JOURNAL OF KIDNEY DISEASES
AD Program Evaluation Branch, Health Standards and Quality Bureau, **Health Care Financing** Administration, Baltimore, MD.
LA Eng
AB The **Health Care Financing** Administration maintains a wide array of data systems that are essential to the functioning of the Medicare program. These data, collected and maintained for the purposes of ensuring entitlements and payment for services, also can be used to monitor programmatic changes and to define potential problem areas. The end-stage renal disease (ESRD) Program Management and Medical Information System (PMMIS) is a subset of the larger Medicare statistical system. It is a historic record of all Medicare ESRD beneficiaries dating back to 1978. Basic Medicare enrollment information on ESRD beneficiaries is enhanced with the addition of information on the cause of renal failure, type of dialysis therapy, transplantation history, and cause of death. The ESRD PMMIS has been put to a number of uses in the past decade or so, ranging from basic descriptive epidemiology to analyses of mortality rates to assessments of programmatic issues such as the composite rate and dialyzer reuse. Because of the limited clinical detail in the PMMIS, there are many specific questions that cannot be adequately addressed. With approval of the Food and Drug Administration and Medicare coverage of erythropoietin, a erythropoietin monitoring system was developed to assess utilization trends of this anemia control drug. Within a few

months it became evident that dosing levels for erythropoietin were much lower than expected from the clinical trials. Following a change in the payment method from a fixed amount to one based on dose level, dosing has increased markedly. However, hematocrit levels still remain below optimal levels. This lack of hematocrit response has led the **Health Care Financing** Administration, in concert with the renal community, to target anemia control as a potential health care quality improvement project. This paper presents an example of the type of data presentation that can be derived from the current PMMIS. The Health Standards and Quality Bureau has made a commitment to a program of continuous quality improvement. Part of this process is the provision of descriptive data that can be the starting point for an iterative approach to quality improvement.

JT AMERICAN JOURNAL OF KIDNEY DISEASES
AD Department of Medicine, Boston University Medical Center, MA 02118.
LA Eng
AB As the federal end-stage renal disease (ESRD) program enters its third decade, it continues to grow both in terms of patient enrollment and cost. High visibility as well as patient, physician, and societal concerns regarding ESRD treatment outcomes and expenditures make the development of improved and expanded quality assurance and improvement (QA/QI) mechanisms for the ESRD program vital. The purpose of a QA/QI program is to identify and apply techniques for assessing and improving ESRD care quality to achieve the best possible outcome for all patients who can benefit medically, within the expenditure constraints set by society. Current QA knowledge and methods are reviewed in this article and are judged to be useful but of limited value. Limitations of current quality assessment tools, provider resistance, and inadequate governmental support are substantial barriers to implementation of a QA

program. An ESRD QA/QI program should develop improved QA tools at the same time that available tools are cautiously put to work. Such a program would be based in individual treatment units, using existing network and US Renal Data System structures and a new national ESRD QA committee for support and oversight. As additional ESRD QA data become available, providers would incorporate the new information into decision making at all levels to enhance patient outcome. Substantial financial support from the government will be needed to implement such a quality program. A comprehensive ESRD QA program could serve as a model for QA for the national health care system.

 TI Empirical Bayes methods for estimating hospital-specific mortality rates.
 SO Stat Med 1994 May 15;13(9):889-903
 JT STATISTICS IN MEDICINE
 AD Educational Testing Service, Princeton, NJ 08541.
 LA Eng
 AB We present alternative methods for estimating hospital-level mortality rates to those used by the Health Care Finance Administration for Medicare patients. We use an empirical Bayes model to represent the different sources of variation in observed hospital-specific mortality rates and we use a logistic regression model to adjust for severity differences (in patient mix) across hospitals. In addition to providing a principled derivation of a standard error for the commonly used estimator, our fully model-based formulation produces much more accurate estimates and resolves the severe problem of multiple comparisons that arises when extreme estimates are used to identify exceptional hospitals. We estimate models for each of four disease conditions using the national Medicare mortality data base which does not contain patient severity descriptors, and mortality data from national samples which do include patient severity descriptors. We find substantial between-hospital variation in the unadjusted death rates from the national data base. Mortality rates differ substantially with patient severity in our models, but the sample sizes are too small to yield reliable estimates of the between-hospital variation in adjusted mortality rates.

TI The value of the Uniform Clinical Data Set System (UCDSS) in a hospital setting.
SO Jt Comm J Qual Improv 1994 Mar;20(3):140-51
JT JOINT COMMISSION JOURNAL ON QUALITY IMPROVEMENT
AD Family and Community Medicine, Medical College of Wisconsin, Milwaukee 53226.

LA Eng
AB BACKGROUND: The **Health Care Financing** Administration designed the Uniform Clinical Data Set System (UCDSS) to help peer review organizations (PROs) identify problems with patient care. The system currently is being piloted in five states and may be used for the PRO review of Medicare patients from all states by January 1995. This study tested whether UCDSS could be used with modifications for effective internal hospital quality review. METHODS: The UCDSS includes a computer program for collecting information from the medical record and 359 computerized algorithms that evaluate quality of care. For this study, 2,313 randomly chosen medical records from a tertiary care teaching hospital were abstracted with the UCDSS at the time of discharge. Cases flagged by the UCDSS algorithms as having potential quality-of-care problems were referred to a clinical reviewer to evaluate whether the flag was a true positive and to identify reasons for false-positive flags. The algorithms were modified based on this hospital's experience by adding the reasons for false-positive flags as exceptions to the algorithm rules. RESULTS: To abstract the data with the UCDSS required a median time of 45 minutes and a mean time of 55 minutes per medical record. The percentages of algorithm flags that were confirmed upon physician review to have a quality problem were estimated to be 21% for the UCDSS and 43% for the modified UCDSS. The confirmed problem rate varied substantially by algorithm. Confirmed problems were the source of numerous departmental and individual discussions and led to changes in five departmental procedures. CONCLUSIONS: Although the results of this study are preliminary and require further verification, they suggest that with modifications and careful attention to implementation, the UCDSS may be an expensive but potentially useful tool for in-hospital quality review. In-hospital employment of the UCDSS offers more opportunities for practical use of algorithms for continuous quality improvement rather than the sometimes punitive use of system findings by PROs.

TI Protein intake and risk of renal cell cancer.

SO J Natl Cancer Inst 1994 Aug 3;86(15):1131-9

JT JOURNAL OF THE NATIONAL CANCER INSTITUTE

AD Division of Cancer Etiology, National Cancer Institute, Bethesda, Md.

LA Eng

AB BACKGROUND: Renal cell cancer, although still relatively uncommon, has been increasing in incidence in the United States and other countries around the world. PURPOSE: Since previous studies have suggested an association with high intake of meat, we sought to further examine the role of diet in renal cell cancer risk. METHODS: Patients with histologically confirmed renal cell cancer that had been diagnosed between July 1, 1988, and December 31, 1990, were identified through the Minnesota Cancer Surveillance System, a statewide cancer registry. The patients eligible for inclusion in this study were white residents of Minnesota between 20 and 79 years of age. Control subjects were selected from the general population of Minnesota residents; subjects under age 65 were selected by use of a random-digit-dialing method and those 65 years or older were sampled from the **Health Care Financing** Administration files. Population-based control subjects were frequency-matched to cases by sex and 5-year age groups. A total of 690 patients and 707 control subjects were interviewed. Patients and control subjects were similar in distribution by sex, age, and educational level. Usual adult dietary intakes were assessed by questionnaire, and odds ratios were calculated by logistic regression analyses. RESULTS: Significantly increased risks of renal cell cancer were observed with increasing consumption of several food groups, including red meat (P for trend = .05), high-protein foods (P = .01), and staple (grains, breads, and potatoes) foods (P = .009). When examined by macronutrient status, risks increased monotonically with the amount of protein intake, from 1.2 (95% confidence interval [CI] = 0.7-1.9) to 1.4 (95% CI = 0.8-2.5) and 1.9 (95% CI = 1.0-3.6) (P for trend = .03) in the second, third, and fourth quartiles of intake, respectively, after adjustment for age, sex, caloric intake, body mass

index, and cigarette smoking. No significant or consistent associations were detected with the intake of other dietary nutrients or beverages.

CONCLUSION: Although an independent effect of dietary protein has not been previously associated with renal cell cancer, high protein consumption has been related to development of other chronic renal conditions that may predispose an individual to this cancer.

IMPLICATION: These findings should prompt further study of dietary protein and its potential contribution to the origins of renal cell cancer.

TI Efficacy of rehabilitation interventions in rheumatic conditions.
SO Curr Opin Rheumatol 1994 Mar;6(2):153-8
JT CURRENT OPINION IN RHEUMATOLOGY
AD Brigham and Women's Hospital, Department of Rheumatology/Immunology, Boston MA 02115.
LA Eng
AB All industrialized nations are facing a crisis in **health care financing**. Rising expectations coupled with increasing specialization and technologic capacities have forced health care payers to examine their assumptions and to seek data on the outcomes of medical interventions. Clinical investigators who have been taught to use randomized controlled trials that evaluate efficacy under experimental conditions have been redirected toward studies that can help answer health policy questions. Such studies examine the effectiveness of interventions in more realistic settings on a richer array of patient-centered outcomes such as function and consider cost effectiveness and relative cost effectiveness. Rehabilitation interventions, which are by and large pragmatic, have never had a strong

scientific basis grounded in controlled trials, and this lack of evidence has put tremendous pressure on clinicians to justify their practices. In this article, we review the recent literature on effectiveness of rehabilitation interventions in rheumatic disorders.

TI Hospitalizations with adverse events caused by digitalis therapy among elderly Medicare beneficiaries.
SO Arch Intern Med 1994 Jul 11;154(13):1482-7
JT ARCHIVES OF INTERNAL MEDICINE
AD Office of Research, **Health Care Financing** Administration, Baltimore, Md.
LA Eng
AB BACKGROUND: Digitalis products are among the agents most frequently prescribed to the elderly, yet previous studies have not provided age-, race-, and sex-specific rates of utilization of digitalis by this population. Estimates of the rate of hospitalization with an adverse reaction from digitalis therapy have varied considerably between systems relying on passive reports and those using active surveillance. METHODS: Medicare data from 1985 through 1991 and data from the 1987 National Medical Expenditure Survey were used to determine population-based estimates of the use of digitalis in elderly beneficiaries by age group, sex, and race. Hospitalization rates with an adverse event caused by digitalis therapy were calculated for those persons estimated to be using digitalis. Medicare data were used to identify the frequency of selected comorbidities among persons with an adverse event caused by digitalis therapy as well as the frequency of clinical manifestations associated with digitalis intoxication. RESULTS: Over 3 million Medicare beneficiaries were estimated to be using digitalis in 1987. A total of 202,011 hospitalizations with a coded adverse event caused by digitalis therapy were reported during the 7-year study period. Of persons estimated to be using digitalis, 8.53 per 1000 were hospitalized annually with an adverse event caused by digitalis therapy. Women, individuals with increasing age, and persons of black race, especially those with impaired renal function, were significantly ($P < .05$) more likely to experience hospitalization with an adverse event caused by digitalis therapy. CONCLUSION: This information may help identify categories of elderly patients who require more frequent monitoring to prevent adverse effects of digitalis therapy. Changes in the format of the hospital bill to include more diagnoses along with increased mandatory reporting of adverse drug events will improve the sensitivity of Medicare data for surveillance of adverse drug events.

TI The economic status of trauma centers on the eve of health care reform.

SO J Trauma 1994 Jun;36(6):835-44; discussion 844-6

JT JOURNAL OF TRAUMA

AD Department of Surgery, Scripps Memorial Hospital, La Jolla, CA
92038-0028.

LA Eng

AB An in-depth understanding of the economic problems confronting trauma centers is essential for their continued development and to address impending changes of health care reform. A comprehensive financial and demographic survey was sent to 839 hospitals identified as potential trauma centers. A total of 313 surveys from 48 states were returned. Extensive information was collected in several areas including financial status (58% reported serious financial problems and 36% reported minor financial problems; 68% reported a financial loss), cost containment and management strategies, marketing, "halo" effect (53% reported positive effect), operational impacts, physician support (47% reported problems), malpractice (92% reported no special problem), role of auto insurance reimbursement, and access to rehabilitation. Detailed financial data of actual costs and reimbursements (95 respondents) were analyzed with the costing method used by the **Health Care Financing** Administration (HCFA). These data will allow us to develop better strategies to deal with the problems of uncompensated and underfunded trauma care and improve trauma center viability.

SO J Health Polit Policy Law 1994 Spring;19(1):7-26
JT JOURNAL OF HEALTH POLITICS, POLICY AND LAW
AD Yale University.
LA Eng
AB While support for the development of clinical guidelines is widespread, there is little agreement about how they should be used. Because cost control is the force behind the medical effectiveness movement, the payers' preference, to link clinical guidelines to reimbursement, will likely prevail. We examine the utilization review programs of Medicare Part B carriers and the carriers' attempts to use clinical guidelines to determine medical necessity for the purpose of payment. We find that because the utilization review programs are driven by concerns about cost control, the carriers' actual review process relies on aggregate utilization and spending targets that have little to do with clinical guidelines. The carriers' medical review rhetoric--using the terms medically unnecessary and fraud and abuse as synonyms--also highlights their focus on cost control and the lack of concern about why services are used inappropriately.

TI MDS Cognitive Performance Scale.
SO J Gerontol 1994 Jul;49(4):M174-82
JT JOURNAL OF GERONTOLOGY
AD Hebrew Rehabilitation Center for Aged, Boston.
LA Eng
AB BACKGROUND. Chronic cognitive impairment is a major problem in U.S. nursing homes, yet traditional assessment systems in most facilities included only limited information on cognitive status. Following the Congressional mandate in the Omnibus Reconciliation Act of 1987 (OBRA '87), U.S. nursing homes now complete the Minimum Data Set (MDS), a standardized, comprehensive assessment of each resident's functional, medical, psychosocial, and cognitive status. We designed a Cognitive Performance Scale (CPS) that uses MDS data to assign residents into easily understood cognitive performance categories. METHODS. Information was drawn from three data sets, including two multistate data sets constructed for the **Health Care Financing** Administration. The prevalence and reliability of the MDS cognitive performance variables were established when assessed by trained nursing personnel. Five selected MDS items were combined to create the single, functionally meaningful seven-category hierarchical Cognitive Performance Scale. RESULTS. The CPS scale corresponded closely with scores generated by the Mini-Mental State Examination and the Test for Severe Impairment, nursing judgments of disorientation, and neurological diagnoses of Alzheimer's disease and other dementias. CONCLUSIONS. The new CPS provides a functional view of cognitive performance, using readily available MDS data. It should prove useful to clinicians and investigators using the MDS to determine a resident's cognitive assets.

TI Medical-care expenditures attributable to cigarette smoking--United States, 1993.
SO MMWR Morb Mortal Wkly Rep 1994 Jul 8;43(26):469-72
JT MMWR. MORBIDITY AND MORTALITY WEEKLY REPORT
LA Eng
AB Cigarette smoking is the most important preventable cause of morbidity and premature mortality in the United States; however, approximately 48 million persons aged > or = 18 years are smokers (1), and approximately 24 billion packages of cigarettes are purchased annually (2). Each year, approximately 400,000 deaths in the United States are attributed to cigarette smoking (3) and costs associated with morbidity attributable to smoking are substantial (4). To provide estimates for 1993 of smoking-attributable costs for selected categories of direct medical-care expenditures (i.e., prescription drugs, hospitalizations, physician care, home-health care, and nursing-home care), the University of California and CDC analyzed data from the 1987 National Medical Expenditures Survey (NMES-2) and from the **Health Care Financing** Administration (HCFA). This report summarizes the results of the analysis.

TI Periodicity of hospital admissions for inflammatory bowel disease.
SO Am J Gastroenterol 1994 Jun;89(6):847-51
JT AMERICAN JOURNAL OF GASTROENTEROLOGY
AD Department of Veterans Affairs Medical Center, Milwaukee, Wisconsin.
LA Eng
AB OBJECTIVES: It has been speculated that exacerbations of inflammatory

bowel disease are influenced by seasonal variations. METHODS: This hypothesis was tested in a large data base of the **Health Care Financing** Administration (HCFA), consisting of all hospitalized US Medicare beneficiaries from four consecutive years. RESULTS: The total of hospital admissions (for all diagnoses) was characterized by a marked seasonal variation occurring similarly in each consecutive year. It was high during winter and low during summer. Peak and trough of admission rate varied by 10%. In striking contrast to this general pattern, both Crohn's disease and ulcerative colitis showed an annual pattern of variability without any clear-cut seasonality. However, the time trends of both diseases showed a striking parallelism concerning their short-term changes (affecting 1-3 consecutive months) and long-term changes (affecting 4-8 consecutive months). The parallelism of the temporal changes affected different age and sex groups alike. CONCLUSIONS: The parallel monthly variations suggest that exacerbations in the activity of inflammatory bowel disease may be modulated by exogenous factors, and that Crohn's disease and ulcerative colitis may be influenced by identical modulators of disease activity.

TI Environmental tobacco smoke and lung cancer in nonsmoking women. A multicenter study.
SO JAMA 1994 Jun 8;271(22):1752-9
JT JAMA
AD Department of Pathology, Louisiana State University Medical Center, New Orleans 70112-1393.
LA Eng
AB OBJECTIVE--To determine the relative risk (RR) of lung cancer in lifetime never smokers associated with environmental tobacco smoke (ETS) exposure. DESIGN--Multicenter population-based case-control study. SETTING--Five metropolitan areas in the United States: Atlanta, Ga, Houston, Tex, Los Angeles, Calif, New Orleans, La, and the San Francisco Bay Area, Calif. PATIENTS OR OTHER PARTICIPANTS--Female lifetime never smokers: 653 cases with histologically confirmed lung cancer and 1253 controls selected by random digit dialing and random sampling from the **Health Care Financing** Administration files for women aged 65 years and older. MAIN OUTCOME MEASURE--The RR of lung cancer, estimated by adjusted odds ratio (OR) with 95% confidence interval (CI), associated with ETS exposure. RESULTS--Tobacco use by spouse(s) was associated with a 30% excess risk of lung cancer: all types of primary lung carcinoma (adjusted OR = 1.29; $P < .05$), pulmonary adenocarcinoma (adjusted OR = 1.28; $P < .05$), and other primary carcinomas of the lung (adjusted OR = 1.37; $P = .18$). An increasing RR of lung cancer was observed with increasing pack-years of spousal ETS exposure (trend $P = .03$), such that an 80% excess risk of lung cancer was observed for subjects with 80 or more pack-years of exposure from a spouse (adjusted OR = 1.79; 95% CI = 0.99 to 3.25). The excess risk of lung cancer among women ever exposed to ETS during adult life in the household was 24%; in the workplace, 39%; and in social settings, 50%. When these sources were considered jointly, an increasing risk of lung cancer with increasing duration of exposure was observed (trend $P = .001$). At the highest level of exposure, there was a 75% increased risk. No significant association was found between exposure during childhood to household ETS exposure from mother, father, or other household members; however, women who were exposed during childhood had higher RRs associated with adult-life ETS exposures than women with no childhood exposure. At the highest level of adult smoke-years of exposure, the ORs for women with and without childhood exposures were 3.25 (95% CI, 2.42 to 7.46) and 1.77 (95% CI, 0.98 to 3.19), respectively. CONCLUSION--Exposure to ETS during adult life increases risk of lung cancer in lifetime nonsmokers.

 TI The antitrust risks of management services organizations, medical foundations, and integrated delivery systems.
 SO Top Health Care Financ 1994 Spring;20(3):37-45
 JT TOPICS IN **HEALTH CARE FINANCING**
 LA Eng
 AB This chapter focuses on the antitrust implications of forming a fully integrated delivery system. The danger lies in a challenge by the federal government or private parties, if the proposed system threatens the development of competing systems or excludes individuals or entities. By explaining the risks facing less integrated arrangements involving medical foundations and management services organizations, why forming an integrated system may resolve some of those risks, and the advantages and disadvantages of other options, this chapter also points out one of the primary benefits of forming an integrated system: reducing the antitrust risks. Finally, general suggestions are posed to minimize the antitrust risks when planning and developing any collaborative effort among providers.

 TI Sowing the seeds of reform in 1994 [see comments]
 SO Health Aff (Millwood) 1994 Spring;13(1):57-68
 JT HEALTH AFFAIRS
 AD Brookings Institution, Washington, DC.
 LA Eng
 AB The prospects for reforming **health care financing** revolve around five questions: (1) Will Congress mandate universal coverage? (2) Will Congress require employers to pay most of the cost of employee coverage? (3) Will Congress authorize effective limits on health care spending? (4) What role should regional health alliances play in the reformed system? (5) How much change in health insurance arrangements can be implemented over the remainder of this decade? The author argues that the prospects are slight for quickly implementing reforms as sweeping as those that President Clinton has proposed. But prospects are good for beginning a process that will lead to universal coverage and effective cost controls. The key is the creation of regional alliances.

JT MISSOURI MEDICINE
AD Missouri State Center for Health Statistics, Missouri Department of Health.
LA Eng
AB Historically, the overall health status as measured by life expectancy and infant mortality of Black and White Missourians has been significantly different. We analyzed birth, death, child death and communicable disease data to determine if Blacks have narrowed the gap in health status. The overall health status of Black and White Missourians improved over the last two decades. However, the gap in health status still remains, and in some cases, has gotten worse. This occurred despite the increase in **health care financing** through Medicare and Medicaid. To narrow the gap in health status between Blacks and Whites requires addressing prevention and the social problems along with the medical problems.

TI Variation in practice for discretionary admissions. Impact on estimates of quality of hospital care.
SO JAMA 1994 May 18;271(19):1493-8
JT JAMA
AD Department of Quality and Utilization, Kaiser Permanente Medical Care Program, Oakland, CA 94612.
LA Eng
AB OBJECTIVE--To demonstrate theoretically and empirically the existence of systematic bias in commonly reported standardized hospital mortality ratios when variation in hospital admission practice is not adjusted for in the analysis. The underlying analytic model used in hospital mortality analyses is specified and the confounding effect of selection bias arising from variation in admission practice is shown. DATA SOURCES--An empirical example is presented using state-level data from the **Health Care Financing** Administration's Medicare Hospital Information Report for 1988 to 1990. STUDY SELECTION--The Medicare Hospital Information data are used to demonstrate the effects of the bias because they contain population-based admission rates and mortality rates. DATA SYNTHESIS--Selection bias arising from variation in admission practice causes the expected mortality rate to be overestimated for all hospitals, but especially for hospitals with more lenient admission practices. Using the Medicare Hospital Information Report, the resulting standardized hospital mortality ratios are shown to be significantly inversely correlated with higher relative risks of hospitalization ($P < .01$). CONCLUSION--Standardized hospital mortality ratios based on analyses that do not account for variation in admission practice among hospitals are biased. Variation in admission practice will cause any outcome measure based solely on hospitalized patients to be similarly biased. Correction for selection bias is required to produce valid measures of hospital quality.

TI Using administrative data to screen hospitals for high complication rates.
SO Inquiry 1994 Spring;31(1):40-55
JT INQUIRY
AD Department of Medicine, Harvard Medical School, Boston, MA.
LA Eng
AB Medicare's Peer Review Organizations (PROs) now are required to work with hospitals to improve patient outcomes. Which hospitals should be targeted? We used 1988 California discharge data to identify hospitals with higher-than-expected rates of complications in six adult, medical-surgical patient populations. Relative hospital complication

rates generally were correlated across clinical areas, although correlations were lower between medical and surgical case types. Higher relative rates of complications were associated with larger size, major teaching facilities, and provision of open heart surgery, as well as with coding more diagnoses per case. Complication rates generally were not related significantly to hospital mortality rates as calculated by the **Health Care Financing** Administration. Different hospitals may be chosen for quality review depending on the method used to identify poor outcomes.

AB Workplace drug and alcohol abuse imposes substantial costs on employers. In response, employers have implemented a variety of programs to decrease substance abuse in the workplace, including drug testing,

health and wellness programs, and employee assistance programs (EAPs). This paper focuses on the relationship between enterprises' organizational and health insurance characteristics and the firms' decisions to provide EAPs. Using data from the 1989 Survey of Health Insurance Plans (SHIP), sponsored by the **Health Care Financing** Administration (HCFA), we estimated the prevalence of EAPs by selected organizational and health insurance characteristics for those firms that offer health insurance to their workers. In addition, we estimated logistic models of the enterprises' decisions to provide EAPs as functions of the extent of state substance abuse and mental health insurance mandates, state-level demographic variables, and organizational and health insurance characteristics. Our results suggest that state mandates and demographic variables, as well as organizational and health insurance characteristics, are important explanatory variables of enterprises' decisions to provide EAPs.

TI Measuring the incidence of cancer in elderly Americans using Medicare claims data.
SO Cancer 1994 May 1;73(9):2417-25
JT CANCER
AD Epidemiology Branch, **Health Care Financing** Administration, Baltimore, Maryland 21207.
LA Eng
AB BACKGROUND. The Surveillance, Epidemiology, and End Results (SEER) program of the National Cancer Institute is the most frequently used and best estimate of the incidence of cancer in the United States. Although synthetic estimates based on the SEER information can be used to plan

cancer prevention and intervention programs, the evaluation of these action programs and the monitoring of cancer incidence in states or other geographic areas requires information on the population for whom the program is directed. METHODS. The age-adjusted incidence of six cancers among persons 65 years of age and older for 1986-1987 living in the five states participating in the SEER program was compared with the incidence derived from hospitalization records contained in the **Health Care Financing** Administration's (HCFA) administrative data files. Age-adjusted incidence rates for 1990 developed from HCFA data for persons living in the nine SEER program areas were contrasted with the incidence rates for persons living in the rest of the United States and were developed for each of the 50 states and the District of Columbia. RESULTS. The comparison of the SEER and HCFA overall age-adjusted cancer incidence rates in the elderly for 1986-1987 showed that for four of the six cancers (breast, colon, lung, and corpus uteri) the rates differed by 5% or less. The HCFA derived rates were 6.37% and 7.65% greater than the SEER rates for prostate and esophagus cancer, respectively. The incidence of cancer between 1986 and 1990 was neither uniformly higher nor lower among elderly SEER program area residents compared with residents of the rest of the country. Incidence rates varied greatly among states for each of the cancers. CONCLUSIONS. HCFA administrative data can be used by states or other geographic units to monitor the incidence of cancer in the elderly as well as to plan and evaluate cancer prevention and intervention programs.

 AB The Cardiovascular Health Study (CHS) is a longitudinal population-based study of coronary heart disease and stroke in men and women 65 years and older. The initial CHS cohort consisted of 5201 men and women recruited from a random sample of the **Health Care Financing** Administration (HCFA) Medicare eligibility lists in four communities in the United States. Extensive historical, physical, and laboratory evaluations were performed at the baseline examination in 1989 to 1990 to identify risk factors and subclinical disease. Periodic contacts are carried out to ascertain and verify incident cardiac and stroke events and their sequelae. Since only a short time has passed since entry of all the patients into the study, data are not available on time trends in the mortality rate of stroke, but we expect to contribute in this area in the years ahead. This article then is a description of the CHS, of methods of assessing stroke in the CHS cohort, and of prevalence of stroke and transient ischemic attacks at the initial examination.

AB PURPOSE: To determine trends in mammography in the United States.
 MATERIALS AND METHODS: A sample of mammographic facilities was selected for each year of the Nationwide Evaluation of X-ray Trends. The same protocol was followed for the 1985, 1988, and 1992 surveys. Data were collected with use of the same imaging phantom for all three surveys and also with a different phantom in the 1988 and 1992 surveys. RESULTS: Of the 356 facilities surveyed in 1992, 59% claimed to be in compliance with the **Health Care Financing** Administration (HCFA) mammography requirements, 42% were accredited by the American College of Radiology (ACR), and 23% did not hold credentials from either the HCFA or the ACR. Since 1985, there has been a 34% improvement in acceptable phantom image quality score and a 20% decrease in the mean glandular dose. CONCLUSION: Mammography as practiced today is essentially a screen-film technique. Mammographic phantom image quality has improved considerably. The overall mean glandular dose has decreased primarily because of the elimination of xeroradiography.

JT ARCHIVES OF FAMILY MEDICINE

AD Department of Medicine, University of Kentucky, Lexington.

LA Eng

AB Graduate Medical Education (GME) payments through the **Health Care Financing** Administration (HCFA) represent the largest portion of federal funding in direct support of training for health professionals. Whatever the benefits of these funds, they clearly have not served as a positive factor in addressing the emerging shortfall of generalist physicians. Therefore, a variety of options are being discussed for restructuring the incentives associated with HCFA GME funds. Seven principal alternatives that have been proposed to address these problems are the following: modification of hospital GME payments, GME payments to medical schools, GME payments to residency programs, GME transfers through Medicare part B, GME transfers to the Health Resources and Service Administration, GME transfers to states through block grants, and GME payments to academic consortia. Unfortunately, each of these approaches offers substantial disadvantages and faces important opposing constituencies. To address these weaknesses, combined strategies and "all payor" federal mechanisms of GME financing have recently been proposed. These compromise approaches have their own administrative and political liabilities as well. Revisions in current HCFA GME payments may be preferable as a first step, but more comprehensive approaches involving all payor financing with mechanisms that reconnect medical school training with primary care practice will likely be required to ensure efficient and effective reform. Such major shifts in the federal funding of GME will not be quick in coming, however, and will doubtless be characterized by a compromise of policy effectiveness with political feasibility.

AB The Health Care Quality Improvement Initiative (HCQII) of the **Health Care Financing** Administration (HCFA) calls for Professional Review Organizations (PROs) to undertake pattern analysis of large administrative datasets for the purposes of quality of care assessment. The limitations of such administrative databases (primarily the MEDPAR file and derivatives thereof) include impoverished information regarding clinical attributes of Medicare enrollees and the process and outcome of their healthcare. This paper describes preliminary efforts to address this problem by the creation of a database, the PRO Concatenated Database (PCD), from the pooled implicit judgment review data of four Peer Review Organizations (PROs). The data elements comprising the PCD were carefully selected to provide important information regarding quality and appropriateness of care. Preliminary inter-state comparative studies employing the PCD are discussed. A method is also described by which the analytical power of state-level databases may be enhanced by linkage to state-level Modeled MEDPAR data which are issued by HCFA and contain patient-level risk-adjusted mortality data. This approach to the acquisition of data whose clinical content is enriched may prove to be particularly useful to the PRO community during the pattern analysis phase of the HCQII. Such analyses will evolve into more detailed studies involving primary data collection followed by dissemination of the results to local healthcare providers. In this manner, the PCD may facilitate rapid feedback regarding the effectiveness of healthcare delivery to the local community.

- AB The distribution of health care services, including craniofacial services in the United States, is examined. The U.S. has a unique ****health care financing**** and organizational system in which persons are most commonly covered by health insurance as a benefit of their employment. Current estimates are that nearly 40 million Americans have no health insurance (Himmelstein et al., 1992). Approximately half of the uninsured persons are in low-wage employment that does not provide health insurance benefits nor allow them to qualify for Medicaid (Pepper Commission, 1990). Personal health care costs now exceed 11% of the U.S. gross domestic product, a significantly higher percentage than that found in other industrialized nations (Consumer Reports, 1990b). Within the current system, is health care distributed in a fair or moral manner? What are the effects of the allocation scheme? Possible changes in ****health care financing**** and delivery are examined and basic ethical and social issues associated with a changing U.S. health care delivery system are explored.

AB To determine trends in a number of hemodialysis associated diseases and practices, the Centers for Disease Control and Prevention in collaboration with the **Health Care Financing** Administration performed a mail survey of chronic hemodialysis centers in the United States in 1991. Of 2,123 centers surveyed, 2,046 (96%), representing 155,877 patients and 40,298 staff members, responded. The 1991 survey found that certain hemodialysis practices are increasing in frequency, including use of bicarbonate dialysate and high-flux dialysis and reuse of disposable dialyzers (in 1991, 71% of centers reused dialyzers). Hepatitis B surface antigen (HBsAg) was present at low frequency in patients (incidence = 0.2%, prevalence = 1.3%) and staff (incidence = 0.04%, prevalence = 0.3%). Among centers that had > or = HBsAg positive patient, the incidence of hepatitis B virus (HBV) infection was lower in those centers that used a separate room for dialysis of HBsAg positive patients. Reuse of dialyzers, blood lines, transducer filters, or dialyzer caps was not associated with an increased risk of acquiring HBV infection among either patients or staff. Antibody to HBsAg was present in 21% of patients and 53% of staff, and was significantly related to

levels of hepatitis B vaccine coverage. Pyrogenic reactions in the absence of septicemia were reported by 20% of centers and associated with the reuse of dialyzers. Human immunodeficiency virus (HIV) was known to be present in 1.2% of patients; 29% of centers reported providing hemodialysis to one or more HIV infected patients.

AB As part of the Medical Case Review Study mandated by the US **Health Care Financing** Administration, the Trans-Atlantic Renal Council obtained urea kinetic data on 244 patients. When analyzed by body weight, the mean Kt/V urea for the 35 patients weighing more than 1 standard deviation over the mean (over 88.1 kg) was 0.943, compared with 1.106 for the remaining 209 patients ($p = 0.007$). The high body weight (HBW) patients were 54% more likely to have a Kt/V less than 1.0 than the remaining patients (68.6% of HBW patients versus 44.5% of control patients, $p = 0.009$). Two-way analysis of variance showed that the tendency to underdialyze HBW patients was present across facilities. Even with the availability of urea kinetic data, HBW patients tend to be less well dialyzed than those of lower body weight.

 TI The case against using the APACHE system to predict intensive care unit outcome in trauma patients.
 SO Crit Care Clin 1994 Jan;10(1):117-26; discussion 127-34
 JT CRITICAL CARE CLINICS
 AD Department of Community and International Health, University of California School of Medicine at Davis.
 LA Eng
 AB The use of outcome indices as a means of evaluating institutional

performance for delivery of medical care is at the forefront of federal health policy reforms. Because an enormous number of clinical and financial data are generated by ICU patients, it is inevitable that integrated bedside computers will be necessary to supply the type of information that is being sought by governmental and private insurance agencies involved in assessment of hospital performance. The **Health Care Financing** Administration already has adopted the APACHE data collection protocols and predictive models for the severity of illness adjustments that were used in assessing the 1986 hospital-specific death rate for acute myocardial infarction, congestive heart failure, stroke, and pneumonia. In our opinion, however, it is unlikely that any single system will be developed that can accurately estimate more than 50% of ICU deaths. The intention of the APACHE III system to include 78 diagnostic categories seems unrealistic. Furthermore, the number of data needed to document outcomes for both low- and high-risk admissions is impractical. We are evaluating APACHE III to determine whether the revisions to the definition for head trauma will represent a significant improvement in predicting outcomes for trauma patients. In the interim, the financial investment in the APACHE III automated bedside data collection system cannot be justified for trauma patients. Neither should it be used in ICUs that admit a large number of trauma patients as a tool for monitoring unit efficiency, guiding triage decisions, allocating staff and ICU beds, identifying risks of iatrogenic or other potential complications, or assessing quality of life, in spite of marketing efforts by the APACHE Corporation. We believe that using any of the APACHE systems for these purposes, at best, is premature, and potentially misrepresents the trauma patient population. Standards for patient classification already are in place for use in making determinations for institutional reimbursement from governmental and insurance agencies. The inequities for certain subgroups of patients, including trauma patients, could create situations in which care is rationed rather than allocated according to a plan that distributes resources efficiently. The APACHE system has several shortcomings and adds little, if anything, to the potential solutions for trauma quality assurance and resource allocation. Nor has the APACHE system established procedures for documenting institutional review of unexpected trauma deaths that would be equivalent, for example, to the type of audit filters applied by the American College of Surgeons in conjunction with the TRISS methodology.(ABSTRACT TRUNCATED AT 400 WORDS)

TI The effect of the Medicare regulations on hospice practice: enhancing staff performance.
SO Am J Hosp Palliat Care 1993 Mar-Apr;10(2):26-31
JT AMERICAN JOURNAL OF HOSPICE AND PALLIATIVE CARE
LA Eng
AB The purpose of this paper is to examine the federal hospice regulations (42 CFR 418.50-.100) and identify from these standards key characteristics that help define important aspects of palliative hospice care. The other purpose will be to examine these requirements to determine what these standards say or imply about the functioning of the hospice staff within the certified program. We assert that in order for a certified program to function in the capacity outlined in the federal hospice requirements, both the administration and staff need to understand, and then practice, the complex role delineated within the Congressional Law and ensuing regulations. The Medicare hospice regulations are a recognized program standard throughout the nation. These requirements, finalized in 1983, were developed by the **Health Care Financing** Administration (HCFA) as a result of the Congressional Tax Equity and Fiscal Responsibility Act (TEFRA, 1982). Since the promulgation of these regulations, hospices wishing to gain certification have had to adapt and mold their program focus and clinical procedures to meet this legislative mandate. Although some hospice administrators may perceive the Medicare requirements simply as hoops to be jumped through in order to gain funding, in truth, these regulations stand as a benchmark in the history of American hospice care. In their totality, the rules set forth a system of health care that is singular in program design.

AB OBJECTIVE. Although the **Health Care Financing** Administration (HCFA) uses Medicare hospital mortality data as a measure of hospital quality of care, concerns have been raised regarding the validity of this concept. A problem that has not been fully evaluated in these data is the potential confounding effect of illness severity factors associated with referral selection and hospital mortality on comparisons of risk-adjusted hospital mortality. We address this issue. DATA SOURCES AND STUDY SETTING. We analyzed the 1988 Medicare hospitalization data file (MEDPAR). We selected data on patients treated at the two Mayo Clinic-associated hospitals in Rochester, Minnesota, and a group of seven other hospitals that treat many patients from large geographic areas. These hospitals have had observed mortality rates substantially lower than those predicted by the HCFA model for the period 1987-1990. STUDY DESIGN. Using the multiple logistic regression model applied by HCFA to the 1988 data, we evaluated the relationship between distance from patient residence to the admitting hospital and risk-adjusted

hospital mortality. PRINCIPAL FINDINGS. Among patients admitted to Mayo Rochester-affiliated hospitals, residence outside Olmsted County, Minnesota was independently associated with a 33 percent lower 30-day mortality rate ($p < .001$) than that associated with residence in Olmsted County. When patients at Mayo hospitals were stratified by residence (Olmsted County versus non-Olmsted County), the observed mortality was similar to that predicted for community patients (9.6 percent versus 10.2 percent, $p = .26$), whereas hospital mortality for referral patients was substantially lower than predicted (5.0 percent versus 7.5 percent, $p = < .001$). After incorporation of the HCFA risk adjustment methods, distance from patient residence to the hospitals was also independently associated with mortality among the Mayo Rochester-affiliated hospitals and seven other referral center hospitals. CONCLUSIONS. The HCFA Medicare hospital mortality model should be used with extreme caution to evaluate hospital quality of care for national referral centers because of residual confounding due to severity of illness factors associated with geographic referral that are inadequately captured in the extant prediction model.

JT TOPICS IN **HEALTH CARE FINANCING**
LA Eng
AB The development of integrated health care systems holds many pitfalls as well as potentials. This case study describes the development of the strategy that has moved the structure, mission, and vision of a health care system. It examines the questions of what members, payers, and providers' needs are when defined around the paradigm of responsibility for the health as well as the health care of a population. It starts by examining the background of the development of the strategies used by the health system during the past decade, and the environmental climate that has led to a redefinition of the mission and vision of the organization. This movement has moved the focus on acute health services to the development of a regional integrated health care system based on collaboration and on a responsibility to improve the health of those we serve through treatment, prevention, and education. Finally, the chapter reviews the options facing all of us: do we compete, collaborate, or both?

AB As managed care organizations (MCOs) develop in the 1990s, a challenge
for managers is the transformation of data into information. This
transformation process is responsible for organizations developing
decision support systems. Decision support enables an individual to
combine financial analysis and operational data to enhance managerial
decision making and strategic planning, and institute the closed-loop
process. This system evolution will help to determine those MCOs that
will become more adept at enhancing profitability and streamlining
decision making.

JT TOPICS IN **HEALTH CARE FINANCING**
AD Ernst & Young, San Francisco, California.
LA Eng
AB Spurred by competition and the growth of managed care, providers are seeking new approaches for satisfying the needs of health care purchasers. Increasingly, these purchasers are focusing on the value of managed care arrangements, especially the degree to which they manage quality. Underlying the emerging focus on quality are concerns about "undercare," potential legal liability, and the economics of quality. Purchasers are sensitive to the quality of service and the experience of their patients, as well as the clinical quality of the care they receive, and many employers are now engaged in a systematic effort to assess both of these dimensions of quality. The emergence of national data banks, practice standards, and accreditation programs offers additional tools for strengthening provider accountability for quality.

Georgetown University Medical Center, Washington, DC.

LA Eng

AB BACKGROUND: A near-total shift to cataract extraction on an outpatient basis occurred as a result of an administrative ruling by the **Health Care Financing** Administration. No national study has been conducted to assess the possible effects of that decision on clinical outcomes of surgery. The authors compared the rates of retinal detachment (RD) repair and hospitalization for endophthalmitis after extracapsular cataract extraction (ECCE) (including phacoemulsification) in 1986 and 1987 with those following inpatient cataract extraction in 1984. METHODS: Using the 5% random sample of Medicare beneficiaries, we analyzed the claims of all individuals 66 years of age or older who underwent ECCE by nuclear expression or phacoemulsification in 1986 and 1987. A total of 57,103 patients were identified and followed to the end of 1988. Cumulative probability of RD repair and hospitalization for endophthalmitis was calculated by standard lifetable methods. These findings were compared with the cumulative probability of the same complications in a cohort of 330,000 patients who underwent cataract extraction on an inpatient basis in 1984. RESULTS: In the 1986-to-1987 cohort, the cumulative probability of RD within 3 years after cataract surgery was 0.81% and the cumulative probability of endophthalmitis within 1 year was 0.08%. The rate of RD is similar to that which we previously reported for 330,000 patients who underwent inpatient surgery in 1984, but the rate of endophthalmitis is significantly lower in the 1986-to-1987 outpatient cohort (0.08% versus 0.12%; $z = 2.42$; $P = 0.01$). CONCLUSIONS: The shift to outpatient cataract surgery was accompanied by no significant increase in the probability of RD repair and possibly a significant decrease in the rate of hospitalization for endophthalmitis.

SO Am Heart J 1994 Feb;127(2):287-95
JT AMERICAN HEART JOURNAL
AD Epidemiology Branch, Office of Research, **Health Care Financing** Administration, Baltimore, MD 21207.
LA Eng
AB Rates of hospitalization among black and white male and female Medicare beneficiaries, 65 years of age and older, for percutaneous transluminal coronary angioplasty (PTCA) and coronary artery bypass graft (CABG) surgery and 30-day postadmission mortality rates were compared for the years 1986 through 1990. The age-adjusted rates of hospitalization for both procedures increased, and the 30-day postadmission mortality rates decreased in all four race-sex groups. The greatest increase in the procedure rates were seen among white males. Using two estimates of the prevalence of ischemic heart disease in the elderly to adjust for the need for these cardiac procedures, the 1990 rates of PTCA in white beneficiaries were between 1.55 and 1.99 times higher than the rates among black beneficiaries, and the rates of CABG surgery were between 1.68 and 2.16 times higher. These differences in revascularization rates raise questions about whether there is equal access to certain treatments in the two race groups.

TI Hospital discharges resulting from esophagitis among Medicare beneficiaries.
SO Dig Dis Sci 1994 Jan;39(1):183-8
JT DIGESTIVE DISEASES AND SCIENCES
AD Division of Gastroenterology, VA Medical Center, Milwaukee, Wisconsin 53295.
LA Eng
AB Despite the frequent occurrence of gastroesophageal reflux disease, until now only very few studies have dealt with the epidemiology of this common disorder. The **Health Care Financing** Administration compiles annually 10 million records of all hospital discharges among Medicare beneficiaries distributed throughout the United States. The purpose of the present study was to take advantage of this large data set and analyze the demographic characteristics of patients discharged with esophagitis, esophageal ulcer, or esophageal stricture. The hospital discharge rates of all three diagnoses showed an age-related rise, the rise being most pronounced for esophageal stricture and, less significant, esophageal ulcer. The marked age dependency of esophageal stricture and ulcer may reflect the time necessary for complications to develop. While simple esophagitis affected women more frequently than men, significantly more men contracted its severe forms involving ulcers and strictures. All forms were more common in whites than blacks, and living in the southern parts of the United States was associated with an increased risk for esophagitis and strictures. The data suggest that besides varying exposure to environmental risk factors, differences in the pathophysiology among demographically stratified groups contribute to the occurrence of esophagitis.

TI Recruitment of adults 65 years and older as participants in the Cardiovascular Health Study [see comments]
SO Ann Epidemiol 1993 Jul;3(4):358-66
JT ANNALS OF EPIDEMIOLOGY

AD Department of Public Health Sciences, Bowman Gray School of Medicine,
Winston-Salem, NC.

LA Eng

AB Few large-scale epidemiologic studies have enrolled older adults; hence,
little is known about the feasibility of recruiting this group for
long-term population-based studies. In this article we present the
recruitment experience of the Cardiovascular Health Study (CHS), a
population-based, longitudinal study of cardiovascular diseases in
adults 65 years and older. Participants were sampled from the **Health
Care Financing** Administration's (HCFA) Medicare eligibility lists in
four US communities. Letters were mailed to 11,955 sampled individuals.
Persons recruited were required to complete an extensive home interview
and then a 4-hour in-clinic examination. Excluded were persons who were
expected to be able to complete the baseline examination and who were
not expected to return for the 3-year follow-up. Some 3654 participants
were recruited from those randomly selected from the Medicare sampling
frame. In addition, 1547 other age-eligible persons living in the
household with the sampled individuals also participated, yielding a
total of 5201 participants. Of those who were contacted, 9.6% were
ineligible and 34.9% refused participation. Among those eligible, 38.6%
refused and 57.3% were enrolled (the remaining did not refuse but were
not enrolled before the recruitment ended). Data from a subsample
indicate that compared to those who were ineligible or who refused,
enrolled participants were younger, more highly educated, more likely to
be married, and less likely to report limitations in activity. Compared
to those who were eligible but refused, enrolled participants were less
likely to have high blood pressure and stroke and more likely to have
quit smoking and to perceive their health status as very good or
excellent.(ABSTRACT TRUNCATED AT 250 WORDS)

TI The association between water fluoridation and hip fracture among white
women and men aged 65 years and older. A national ecologic study.

SO Ann Epidemiol 1992 Sep;2(5):617-26

JT ANNALS OF EPIDEMIOLOGY
AD Medical College of Wisconsin, Milwaukee.
LA Eng
AB For the past 45 years, there has been a great deal of debate regarding the health issues surrounding the fluoridation of public water supplies. In order to assess the association between fluoridation and hip fracture, we identified 129 counties across the United States considered to be exposed to public water fluoridation and 194 counties without exposure. Data from the **Health Care Financing** Administration and the Department of Veterans Affairs were used to calculate the incidence of hip fracture among white persons, aged 65 years or older, in fluoridated and nonfluoridated counties. There was a small statistically significant positive association between fracture rates and fluoridation. The relative risk (95% confidence interval) of fracture in fluoridated counties compared to nonfluoridated counties was 1.08 (1.06 to 1.10) for women and 1.17 (1.13 to 1.22) for men. As comparisons were made at the grouped level, it may be inappropriate at this time to draw inferences at the individual level. The relationship observed at the county level needs to be duplicated at the individual level with more precise measures of fluoride exposure.

TI Changes in employment, insurance, and income in relation to HIV status and disease progression. The Multicenter AIDS Cohort Study.

SO J Acquir Immune Defic Syndr 1994 Jan;7(1):86-91

JT JOURNAL OF ACQUIRED IMMUNE DEFICIENCY SYNDROMES

AD Department of Health Policy and Management, Johns Hopkins School of Public Health, Baltimore, Maryland.

LA Eng

AB While patterns of **health care financing** for HIV have received considerable attention in the literature, the financial impact of disease on individuals living with HIV infection has been underexplored, particularly in relation to disease progression. Therefore, we sought to document changes in employment, income, and insurance coverage over time among HIV-negative, HIV-positive, and AIDS-diagnosed gay and bisexual men participating in the Multicenter AIDS Cohort Study (MACS) and to document measures of financial hardship. Persons with AIDS (PWAs) were 2.7 times more likely to lose full-time employment over a 6-month period than seronegative persons ($p < 0.05$), and loss of employment was strongly associated ($p < 0.001$) with both loss of private health insurance and loss of income. Twenty-seven percent of PWAs reported having financial difficulty meeting their basic expenses, compared with 10% of seronegative ($p < 0.001$), and 15% of PWAs, compared with only 9% of seronegative persons, said that, for financial reasons, they had not sought medical care that they thought they needed ($p = 0.028$). When 27% of PWAs in a cohort such as this report financial difficulty meeting their basic expenses, it is clear that the response of our public health and social welfare systems has not been adequate. Given that the problems experienced by most persons infected by HIV are considerably more severe than those experienced by MACS participants, the imperative for action is even greater.

TI Effect of age and diagnosis on survival of older patients beginning chronic dialysis [see comments]
SO JAMA 1994 Jan 5;271(1):34-6
JT JAMA
AD New York State Department of Health, Stony Brook.
LA Eng
AB OBJECTIVE--To assess the survival of elderly patients in the United States beginning chronic dialysis for end-stage renal disease caused by diabetes mellitus, hypertension, glomerulonephritis, polycystic kidney disease, and other causes. DESIGN--A secondary analysis of data obtained from the **Health Care Financing** Administration. PATIENTS--All Medicare end-stage renal disease patients 55 years of age or older (n = 95,394) who began chronic dialysis treatment in the US between 1982 and 1987. MAIN OUTCOME MEASURES--The 1-, 3-, and 5-year survival rates for each of six age strata and, within each strata, for each of the four most frequent causes of renal failure. RESULTS--Survival rates of dialysis patients fell precipitously, and much more rapidly for the study group than for the general population, as a function of advancing age. Older patients with diabetic nephropathy fared particularly badly, such that no patients with diabetic nephropathy aged 85 years or more survived 5 years. CONCLUSIONS--Mortality rates of patients older than 55 years beginning chronic dialysis treatment increased dramatically as age at initiation of dialysis increased. Clinically meaningful survival data should prove useful to persons making decisions about the initiation of chronic dialysis.

TI Health spending by state: new estimates for policy making.
SO Health Aff (Millwood) 1993 Fall;12(3):7-26
JT HEALTH AFFAIRS
LA Eng
AB A new data set from the **Health Care Financing** Administration gives estimates of state spending for hospital care, physician services, and retail purchases of prescription drugs, which together account for 70 percent of health expenditures nationwide. Analysis of these data, which are the first uniform state data to be produced for nearly ten years, shows considerable variation among states and among regions in health care spending. The New England and Mideast regions show the consistently highest spending levels for all three categories; the Southwest and Rocky Mountain regions spent the smallest amount (as much as 17 percent below the U.S. average).

TI The Uniform Clinical Data Set: an evaluation of the proposed national database for Medicare's quality review program.
SO Ann Intern Med 1993 Dec 15;119(12):1209-13
JT ANNALS OF INTERNAL MEDICINE
AD American College of Physicians, Philadelphia, PA.
LA Eng
AB The accuracy, reliability, and validity of the Medicare Peer Review Organization (PRO) review process have all been questioned. Evidence concerning the PRO program's effect on cost and quality of care remains lacking. The **Health Care Financing** Administration has thus committed itself to reform, and the Uniform Clinical Data Set (UCDS) has been proposed as the national database for Medicare's quality review program. The UCDS is an automated, computerized data set designed to standardize the evaluation of quality. It should allow an objective,

consistent, and efficient process for peer review, based on explicit decision criteria and on aggregated information about patterns of care and quality. But is this truly so? We review the existing evidence on the UCDS and compare it with the current PRO reviews of quality, concluding that although the UCDS can potentially improve the accuracy and the reliability of data abstraction and the validity of reviews, this remains to be shown. Preliminary data on the UCDS suggest that work is needed before it can meet appropriate expectations for a national database for quality assessments. We also propose a model for reviews of quality in which we show that reviews of care done in the context of internal quality improvement programs will differ in goals and intensity from reviews of care done at the national level. We suggest that the UCDS has a unique, but limited role--that of national surveillance of practice patterns. Detailed assessments of quality are more appropriately done at local or institutional levels.

TI Developments in alcoholism treatment.
SO Recent Dev Alcohol 1993;11:369-96
JT RECENT DEVELOPMENTS IN ALCOHOLISM
AD Alcohol Research Group, University of California, Berkeley 94709.
LA Eng
AB Alcohol treatment systems expanded and diversified considerably over the past decade. This reflects adaptation to a variety of forces, including developments in national **health care financing** and policy, changes in other health care systems with which alcohol treatment had strong ties, the more diffuse effects of social movements and a "drying trend" in American public opinion, as well as agitation by advocacy and provider groups within the alcohol field. Drawing on national monitoring data, this chapter reviews developments at the levels of financing policy, organizations, client populations, and treatment modalities, documenting expansion in private sector alcohol treatment units, a growing emphasis on providing outpatient treatment, a merger between services for alcohol and drugs at the organizational and conceptual levels, increases in service delivery to coerced populations, as well as demographic change in alcohol treatment caseloads during the 1980s.

TI The diminishing role of the dermatologist in the office-based care of cutaneous diseases.
SO J Am Acad Dermatol 1993 Nov;29(5 Pt 1):773-7
JT JOURNAL OF THE AMERICAN ACADEMY OF DERMATOLOGY
AD Department of Dermatology, Beth Israel Hospital, Harvard Medical School, Boston, MA 02215.
LA Eng
AB The number of physicians who provide ambulatory care for patients with skin diseases is rapidly increasing. Current and proposed changes in **health care financing** may limit direct access to dermatologists. We provide recent data on volume of visits for cutaneous diagnoses, including the types of medical practitioners who provided these ambulatory services, and compare these data with earlier surveys that span 15 years. In 1989, dermatologists saw 41% of the 51.6 million persons with cutaneous diagnoses. The number of visits per dermatologist declined significantly from 1974 to 1989 ($p < 0.05$). Visits to dermatologists were significantly more likely to be reimbursed by Blue Cross/Blue Shield or self-pay than visits to other physicians for skin problems. From 1974 to 1989, the demand for dermatologic services from dermatologists has not increased as rapidly as the supply of dermatologists. Our data also suggest that restrictions on direct access to dermatologists or changes in reimbursement may substantially decrease the demand for services provided by dermatologists.

TI The peer review organization process revisited.
SO Home Healthc Nurse 1993 Sep-Oct;11(5):67-8
JT HOME HEALTHCARE NURSE
LA Eng
AB The outcomes of patient care are of increasing importance in the 1990s from a quality of patient care perspective. Most of the review processes that HHAs are subjected to, including the Medicare certification survey, the accreditation process by the Joint Commission on the Accreditation of Healthcare Organizations and the Community Health Accreditation Program, are focused toward patient outcomes. Also included is the PRO process that addresses the quality of care issue when home care was provided as one of the intervening care services if a patient is readmitted to an acute care facility within 31 days of discharge, HHA standards as well as professional nursing standards. There is no question that the care rendered and the complete and accurate documentation by home healthcare nurses contribute to the minimal number of confirmed quality of care problems that have been identified in HHAs. We would appreciate findings reported in other states. Please share published information on the PRO activities in your state in care of Home Healthcare Nurse. We look forward to hearing from you.

TI Cancer of the large bowel in women in relation to alcohol consumption: a

case-control study in Wisconsin (United States).
SO Cancer Causes Control 1993 Sep;4(5):405-11
JT CANCER CAUSES AND CONTROL
AD University of Wisconsin-Madison Comprehensive Cancer Center 53706.
LA Eng
AB Age-specific consumption of beer, wine, and liquor was ascertained by telephone interview from 779 women in Wisconsin (United States) with newly reported diagnosis of carcinoma of the colon and rectum. Population controls (n = 2,315) interviewed for this case-control study were randomly selected from Wisconsin driver's license files and **Health Care Financing** Administration files. Overall, there was a modest indication that high levels of alcohol consumption (11 or more drinks per week) were associated with increased risk of large bowel cancer (adjusted odds ratio [OR] = 1.47, 95 percent confidence interval [CI] = 1.0-2.22). In site-specific analyses, only rectal cancer demonstrated a significant linear trend (P = 0.01) with increasing consumption. Significant beverage-specific effects were observed for liquor and colon cancer: the adjusted ORs for 1-2, 3-5, and 6+ drinks per week were 1.12, 1.68, 1.51, respectively (P trend = 0.01). Beer was associated significantly with rectal cancer: the adjusted ORs for 1-2, 3-5, 6-10, and 11+ drinks per week were 1.25, 1.25, 1.58, 2.42, respectively (P trend = 0.02). Wine consumption was associated inversely with these cancers. These relationships appeared to be consistent for recent, past, and total lifetime consumption, and were not attributable to differences in dietary habits.

TI Supporting future surgical innovation. Lung transplantation as a case study.
SO Ann Surg 1993 Oct;218(4):465-73; discussion 474-5
JT ANNALS OF SURGERY
AD Habif Center for Surgical Studies, Columbia University, College of Physicians and Surgeons, New York, NY.
LA Eng
AB OBJECTIVE: Using lung transplantation as a case study, this article addressed the problem of supporting innovative clinical surgery in an era of increasing pressures for cost containment. SUMMARY BACKGROUND DATA: After sporadic attempts at lung transplantation during the 1960s and 1970s, its clinical development began in earnest during the early 1980s. As a result of a wide range of incremental advances, the results have improved significantly. The ****Health Care Financing**** Administration, however, has not yet issued a national policy covering lung transplants and has left the coverage decision to the discretion of its regional contractors. METHODS: The authors surveyed the major commercial insurers, the Blue Cross Blue Shield Association, and a sample of Medicare intermediaries to evaluate the coverage of lung transplantation. They also interviewed the National Heart, Lung, and Blood Institute and industrial firms about their support for clinical research. RESULTS: Government and industry funding were limited, and the development and assessment of lung transplants have been financed predominantly by academic institutions through cross-subsidization from patient care and teaching funds. The major private payers and Blue Cross Blue Shield decided to cover this procedure in the early 1990s. Coverage decisions by Medicare intermediaries, however, revealed considerable variability. Moreover, the absence of a specific diagnosis-related group for lung transplants had considerable consequences for institutions in all-payer states, in which payments appeared to be considerably lower than the mean costs of a transplant procedure (about \$110,000). CONCLUSIONS: This analysis indicated that there was a growing disparity between the increasing demand for outcomes data about new procedures and the limited resources available for supporting the development and assessment of new operations. If this disparity is not addressed, the rate of surgical innovation may be jeopardized, and timely outcomes data may not be acquired. It was concluded that provisional coverage within a predetermined research protocol may be a promising mechanism to remedy this situation, providing timely assessment of new procedures before widespread application.

 TI An analysis of liver transplant experience from 37 transplant centers as reported to Medicare.
 SO Transplantation 1993 Sep;56(3):554-61
 JT TRANSPLANTATION
 AD Bureau of Policy Development, **Health Care Financing** Administration, Baltimore, Maryland 21207.
 LA Eng
 AB Analysis of 5180 liver transplant cases from 37 liver transplant centers in the United States (1982-1991) shows an overall one-year survival rate of 79.4 +/- 0.6% and a five-year survival rate of 69.2 +/- 0.9%. There was marked improvement in the one-year survival rate after liver transplantation from 36.0 +/- 9.6% in 1982 to 85.0 +/- 1.8% in 1991. One-year survival rates after liver transplantation for postnecrotic cirrhosis, primary biliary cirrhosis, alcoholic cirrhosis, primary sclerosing cholangitis, alpha-1-antitrypsin deficiency, and Wilson's

disease ranged from 78.4 +/- 1.0% to 84.2 +/- 1.5% and five-year survival rates from 68.6 +/- 3.8% to 79.2 +/- 5.3%. Survival rates after liver transplantation for hemochromatosis were poor--a one-year survival rate of 53.8 +/- 6.8% and a five year survival rate of 43.1 +/- 11%. One- and five-year survival rates for the 0-13 years age group were 74.6 +/- 2.8% and 66.7 +/- 3.4%; for the 14-37 years age group, 83.3 +/- 1.2% and 73.8 +/- 1.8%; for the 38-54 years age group, 79.6 +/- 0.8% and 69.7 +/- 1.3%; for the 55-63 years age group, 76.0 +/- 1.4% and 63.0 +/- 3.1%; and for the 64-77 years age group, 76.5 +/- 3.0% and 65.4 +/- 4.6%.

TI Medicare beneficiaries: adverse outcomes after hospitalization for eight procedures.
SO Med Care 1993 Oct;31(10):921-49
JT MEDICAL CARE
AD Office of Research and Demonstrations, **Health Care Financing** Administration, Baltimore, MD.
LA Eng
AB Rehospitalization following surgery is widely recognized as an important outcome measure. The purpose of this study was to identify rehospitalizations for adverse events following 8 procedures, using diagnosis and procedure codes contained in Medicare claims files. Adverse events were broadly defined as: 1) complications; 2) failure of the procedure to achieve its therapeutic goal; and 3) untoward events associated with the natural history of the disease being treated with the procedure. Expert panels identified specific diagnosis and procedure codes that might indicate an adverse event if they appeared on the Medicare record of a rehospitalization. Among patients undergoing percutaneous transluminal coronary angioplasty, almost 36% were rehospitalized for an adverse event within a year of surgery; among patients undergoing coronary artery bypass graft surgery, 20% were rehospitalized for an adverse event. Following the other 6 procedures (cholecystectomy, partial excision of the large intestine, total knee replacement, total hip replacement, replacement of the head of the femur, and reduction of fracture of the femur) between 4% and 9% of patients were rehospitalized for an adverse event. Findings from this exploratory study indicate that rehospitalizations for adverse events appear to be a useful outcome measure for the cardiac procedures; they appear to be less useful for the other procedures, at least at the individual hospital or small area level, because of their relative rarity. Future studies should investigate procedures associated with more frequent rehospitalizations, and medical admissions, which often tend to be associated with higher rehospitalization levels.

TI A method for selecting data subsets from large medical data bases.
SO J Med Syst 1993 Apr;17(2):103-15
JT JOURNAL OF MEDICAL SYSTEMS
AD Health Policy Institute, Medical College of Wisconsin, Milwaukee 53226.
LA Eng
AB Because of the exponential increase in health care expenditures, attention has been drawn to the cost and effectiveness of health care delivered. The use of electronic data bases as a means for assessing health care effectiveness has been advocated as powerful computer systems have become commonplace. The need to work efficiently with extremely large data bases presents difficult challenges to researchers who wish to focus on specific aspects of the data. This paper describes a computer program written to facilitate the analysis of large medical data sets by providing a straightforward way to specify and select data subsets from the aggregate data base.

SO Inquiry 1993 Fall;30(3):306-17
JT INQUIRY
AD Department of Health Administration, Virginia Commonwealth University, Richmond 23298-0203.
LA Eng
AB Using a pooled, cross-sectional time-series analysis, this study examines the relationship of financial performance of short-term, inpatient psychiatric hospitals to ownership and system affiliation. After controlling for market variables, case mix, the number of services, and bed size, the results indicate that for-profit psychiatric hospitals had higher revenues per adjusted discharge, higher expenses per adjusted discharge, and higher profitability compared to not-for-profit hospitals. System affiliated psychiatric facilities had lower revenues per adjusted discharge, lower expenses per adjusted discharge, and lower profitability than freestanding facilities.

TI Financial performance of academic medical center hospitals.

SO Acad Med 1993 Oct;68(10):729-31

JT ACADEMIC MEDICINE

AD Program for Health Policy and Health Services Research, Ohio State University, Columbus 43210.

LA Eng

AB In its 1990 report to the U.S. Congress and to the Secretary of Health and Human Services, the Council on Graduate Medical Education noted that the financial status of teaching hospitals, as measured by trends in profit margins, had deteriorated during the years 1985-1988, and that major teaching hospitals had the lowest margins in the hospital industry. To gain insight into the financial viability of major teaching hospitals, the authors updated the analysis of the financial status of these hospitals and further analyzed their financial performance. They identified academic medical center hospitals using criteria established by the Association of American Medical Colleges' Council on Teaching Hospitals; accessed financial performance data on these institutions from the **Health Care Financing** Administration's prospective payment system minimum-data sets for the years 1987-1991; evaluated the financial performance of these institutions for the five-year period by calculating their total margin, return on equity, and financial leverage; and determined the percentage of Medicaid discharges for each year. The analyses show that academic medical center hospitals had stabilized their short-term financial performance in recent years. Nevertheless, their financial position is not strong. Their return on equity and debt financing percentages suggest that they will be forced to reduce their future rate of investment in new plant and equipment. Further, their overall financial performance is threatened by the growing percentage of Medicaid discharges. These observations raise serious concerns about the financial viability of these institutions in the face of continued changes in the financing of hospital services.

TI An evaluation of freestanding alcoholism treatment for Medicare

recipients.

SO Addiction 1993 Jan;88(1):53-68

JT ADDICTION

AD Substance Abuse and Mental Health Services Administration, US Public Health Service, Rockville, Maryland.

LA Eng

AB The **Health Care Financing** Administration (HCFA) and the National Institute on Alcohol Abuse and Alcoholism (NIAAA) conducted a demonstration between 1982 and 1985 to test the feasibility of providing payments for alcoholism treatment services to Medicare and Medicaid recipients in specially selected freestanding facilities. This study of the Medicare part of the demonstration answers two questions: do freestanding facilities save money for Medicare and do their patients have lower health care utilization following initiation of treatment than patients treated in hospital-based facilities? The statistical methodology is a logit and cluster approach. The analysis begins with a logistic regression model to predict the probability of patients seeking alcoholism treatment in either the demonstration (freestanding facility) or hospital-based cohort. The statistically significant variables from logit analysis are then used to form clusters. The health expenditures of freestanding and hospital patients are compared within homogeneous clusters. This study shows that the number of admissions, the average length of stay, and the average monthly health expenditures following the start of treatment are lower for the group treated in the freestanding facilities. The conclusion is that for some persons with alcohol problems, treatment in freestanding facilities is less costly and leads to lower subsequent health care utilization than treatment in hospitals.

 TI National surveillance of hemodialysis associated diseases in the United States, 1990.
 SO ASAIO J 1993 Jan-Mar;39(1):71-80
 JT ASAIO JOURNAL
 AD Investigation and Prevention Branch, Centers for Disease Control, Atlanta, GA 30333.
 LA Eng
 AB To determine trends in several hemodialysis associated diseases and practices, the Centers for Disease Control (CDC), in collaboration with the **Health Care Financing** Administration (HCFA), performed a mail survey of chronic hemodialysis centers in the United States in 1990. Of 1,995 centers surveyed, 1,882 (94%) representing 140,608 patients and 36,907 staff members responded. As in recent years, the 1990 survey found that certain hemodialysis practices are increasing in frequency, including treatment of water with reverse osmosis and deionizer units; use of bicarbonate dialysate and high-flux dialysis; and reuse of disposable dialyzers (in 1990, 70% of centers reused dialyzers). Hepatitis B surface antigen (HBsAg) was present at low frequency in patients (incidence, 0.2%; prevalence, 1.2%) and staff (incidence, 0.04%; prevalence, 0.3%). Antibody to hepatitis B surface antigen was present in 20% of patients and 58% of staff, and was significantly related to levels of hepatitis B vaccine coverage. Pyrogenic reactions in the absence of septicemia were reported by 20% of centers and were associated with use of high-flux dialyzer membranes and reuse of dialyzers (particularly in centers where the maximum number of reuses was 40 or more). Septicemia among hemodialysis patients was reported by 49% of centers. Twenty-six percent of centers reported providing hemodialysis for patients infected with human immunodeficiency virus (HIV), and 1.1% of dialyzed patients had known HIV infection.

TI Trends in diabetes and diabetic complications, 1980-1987.

SO Diabetes Care 1992 Aug;15(8):960-7

JT DIABETES CARE

AD Division of Diabetes Translation, Centers for Disease Control, Atlanta, Georgia 30333.

LA Eng

AB OBJECTIVE--Although diabetes is a major source of morbidity and mortality in the United States, only recently has a unified national surveillance system begun to monitor trends in diabetes and diabetic complications. RESEARCH DESIGN AND METHODS--We established a diabetes surveillance system using data for 1980-1987 from vital records, the National Health Interview Survey, the National Hospital Discharge Survey, and the **Health Care Financing** Administration's records to examine trends in the prevalence and incidence of diabetes, diabetes mortality, hospitalizations, and diabetic complications. RESULTS--From 1980 through 1987, the number of individuals known to have diabetes increased by 1 million--to 6.82 million. Age-standardized prevalence for diabetes increased 9% during this period, from 25.4 to 27.6/1000 U.S. residents ($P = 0.03$). The incidence of diabetes increased among women ($P = 0.003$), particularly among those greater than 65 yr old ($P = 0.02$). Age-standardized mortality rates (for diabetes as either an underlying or contributing cause) per 100,000 individuals with diabetes declined 12%, from 2350 to 2066. Annual mortality rates from stroke (as an underlying cause and diabetes as a contributing cause) and diabetic ketoacidosis declined 29% ($P = 0.003$) and 22% (P less than 0.001), respectively. During these 8 yr, hospitalization rates for major CVD and stroke (as the primary diagnoses and diabetes as a secondary diagnosis) increased 34% ($P = 0.006$) and 38% ($P = 0.01$), respectively. Also during this period, hospitalization rates increased 21% for diabetic ketoacidosis ($P = 0.01$) and 29% for lower-extremity amputations ($P = 0.06$). From 1982 through 1986, treatment for end-stage renal disease related to diabetes increased greater than 10% each year (P less than 0.001). The prevalence of diagnosed diabetes was nearly twice as high in blacks as in whites ($P = 0.04$). Blacks also had increased rates of lower-extremity amputation ($P = 0.02$), diabetic ketoacidosis (P less

than 0.001), and end-stage renal disease ($P = 0.01$).

CONCLUSIONS--Diabetes surveillance data will be useful in planning, targeting, and evaluating public health efforts designed to prevent and control diabetes and its complications.

TI An evaluation of substance misuse treatment providers used by an employee assistance program.
SO Int J Addict 1992 May;27(5):533-59
JT INTERNATIONAL JOURNAL OF THE ADDICTIONS
AD Office of Research and Demonstrations, **Health Care Financing** Administration, Baltimore, Maryland 21207.
LA Eng
AB Structural measures of access, continuity, and quality of substance misuse treatment services were compared in 30 fee-for-service (FFS) facilities and nine health maintenance organizations (HMOs). Probit models related effects of the provider system (FFS or HMO) and the system's structural characteristics to 243 employees' access to and outcomes from treatment. Access was decreased in Independent Practice Association (IPA)/network HMOs and in all facilities which did not employ an addictionologist or provide coordinated treatment services. When bivariate correlations were examined, both use of copayments and imposing limits to the levels of treatment covered were negatively related to access, while a facility's provision of ongoing professional development was positively associated with access. These correlations did not remain significant in the multivariate probits. Receiving treatment in a staff model HMO and facing limits to the levels of

treatment covered were negatively associated with attaining sufficient progress, while receiving treatment in a facility which provided ongoing professional development was positively related to progress: these effects did not remain significant in multivariate analyses.

Implications for employee assistance program (EAP) staff in their role as case managers and for EAP staff and employers in their shared role as purchasers of treatment are discussed.

TI The impact and cost of influenza in the elderly.
SO Arch Intern Med 1993 Sep 27;153(18):2105-11
JT ARCHIVES OF INTERNAL MEDICINE
AD Epidemiology Branch, **Health Care Financing** Administration,
Baltimore, MD 21207.
LA Eng
AB BACKGROUND: Traditional methods of measuring the impact and cost of
influenza virus have focused on epidemic years and morbidity and
mortality due to pneumonia and influenza. METHODS: Annualized
age-sex-race adjusted rates of hospitalization for pneumonia and
influenza and other diagnoses among elderly Medicare beneficiaries
during the epidemic influenza season of 1989 to 1990 and the nonepidemic
season of 1990 to 1991 were compared with an interim period in 1990
without influenza virus circulation. RESULTS: The rates of
hospitalization for pneumonia and influenza, acute bronchitis, chronic
respiratory disease, and congestive heart failure were significantly
greater during each influenza period compared with the interim period.
The highest rates were found in the epidemic season of 1989 to 1990.
The amount reimbursed by Medicare to hospitals to 1990. The amount
reimbursed by Medicare to hospitals for the treatment of excess
hospitalizations during periods of influenza activity was more than \$1
billion in 1989 to 1990 and almost \$750 million in 1990 to 1991.
CONCLUSIONS: Measures of the impact and cost of influenza in elderly
Americans should include all of the diagnoses listed above and should
recognize that the impact of influenza virus is significant even in
nonepidemic years. There are great opportunities for cost savings if
effective control programs are implemented.

TI A longitudinal perspective on patterns of Medicare payments.
SO Health Aff (Millwood) 1993 Summer;12(2):140-50
JT HEALTH AFFAIRS
AD Division of Beneficiary Studies, **Health Care Financing** Administration (HCFA), Baltimore.
LA Eng
AB To provide insight into the stream of Medicare payments over time, a sixteen-year longitudinal study examines three age cohorts of beneficiaries, looking separately at beneficiaries who died during the study period and those who survived. The common wisdom that a small minority of the population accounts for a large majority of health care expenditures is tempered when health care use is examined over an extended period of time. By putting high average costs in the final years of life in the context of a cohort's total lifetime experience,

the study shows a leveling of spending over time, resulting in a lower concentration of health care resources on a small fraction of the population.

TI An ethical perspective on health care insurance reform.
SO Am J Law Med 1993;19(1-2):37-74
JT AMERICAN JOURNAL OF LAW AND MEDICINE
AD Harvard School of Public Health.
LA Eng
AB Much recent analysis of health care insurance reform emphasizes economic and policy issues. In contrast, this Article examines health policy issues from the viewpoint of medical ethics. The critical ethical "problem" in health care today is that ability to pay determines the availability and quality of care. This Article discusses three types of proposed solutions: health care insurance reform, **health care financing** reform, and health care cost reform. It sketches an ethical framework for evaluating health policy and presents seven specific propositions that an ethical analysis of health care reform proposals raises. This Article concludes that remedying the unethical treatment of certain classes of patients requires both **health care financing** reform and health care cost reform; health care insurance reform will not suffice.

SO Clin Ther 1993 May-Jun;15(3):581-92
JT CLINICAL THERAPEUTICS
AD College of Pharmacy, University of South Carolina, Columbia.
LA Eng
AB The Omnibus Budget Reconciliation Act of 1990 (OBRA-90) may be the most significant piece of legislation affecting the practice of pharmacy since the Durham-Humphrey amendments to the Food, Drug and Cosmetic Act. As part of the OBRA-90 legislation, the **Health Care Financing** Administration (HCFA) was required to publish estimates of the impact of the act on states, Medicaid recipients, and pharmacies. Numerous stakeholders and researchers have commented on the HCFA estimates. We have summarized the estimates available in comments and studies and conducted a sensitivity analysis on these estimates. Our results demonstrate considerable variation in the factors important in estimating the impact of OBRA-90 on pharmacy operations. This variation indicates the scarcity of empirical data needed to produce reliable impact estimates. Demonstration projects are needed to scientifically evaluate the total impact of OBRA-90 on pharmacy practice. Moreover, further investigation of the impact of the legislation on program

recipients and states is warranted.

TI Appendectomy incidental to cholecystectomy among elderly Medicare beneficiaries.
SO Surg Gynecol Obstet 1993 Sep;177(3):288-94
JT SURGERY, GYNECOLOGY AND OBSTETRICS
AD Epidemiology Branch, **Health Care Financing** Administration, Baltimore, Maryland.
LA Eng
AB To assess the risks of adverse outcomes after appendectomy incidental to cholecystectomy among elderly Medicare beneficiaries, 8,936 persons undergoing cholecystectomy with incidental appendectomy and 44,461 persons undergoing cholecystectomy without incidental appendectomy were studied. Controlling for age, race, gender and co-morbidity status, the risk for wound infection in persons with incidental appendectomy was 83 percent higher than in persons without incidental appendectomy (95 percent confidence interval, 1.53 to 2.18). The risks for having other adverse outcomes, including other infections, extensive intrahospital complications and mortality rate at 30 days, were also higher for the former group, although these differences were not statistically significant. In addition, the demographic characteristics and health status of persons undergoing cholecystectomy with incidental appendectomy with persons undergoing cholecystectomy only were compared. Males, persons of younger ages, of white race or with no co-morbid conditions, were significantly more likely to undergo cholecystectomy with incidental appendectomy. Variables to control for differences in the demographic characteristics and health status between persons receiving and not receiving incidental appendectomy were included in the regression models for adverse outcomes. However, these models may not completely control for differences between the two groups. As a result, the actual relationship between incidental appendectomy and adverse outcomes may be underestimated. The preventive effect of incidental appendectomy on morbidity and mortality rates from future instances of

appendicitis was assessed by determining the remaining lifetime risk for acute appendicitis. For persons 65 to 69 years of age, 115 incidental appendectomies would be required to prevent one future instance of appendicitis and 4,472 incidental appendectomies would be needed to prevent a single future death from acute appendicitis. Because incidental appendectomy increases the risk for wound infection among persons undergoing cholecystectomy and because the lifetime risk for acute appendicitis is relatively low for persons of this age group, surgeons should carefully consider the risks and benefits of incidental appendectomy in the elderly.

TI **Health care financing** for the elderly in Japan.
SO Soc Sci Med 1993 Aug;37(3):343-53
JT SOCIAL SCIENCE AND MEDICINE
AD Department of Public Health, Teikyo University School of Medicine,
Tokyo, Japan.
LA Eng
AB This paper examines the financing of elderly health care in Japan for medical institutions, nursing homes, and at home. The analysis demonstrates that the conventional figures for elderly health expenditures in Japan systematically underestimate the real costs by excluding the costs of uninsured services, nursing homes, and home health care. The paper estimates these costs and shows that they add about 10% to the conventional figure for elderly health care costs in

Japan. This inquiry also shows how government policy for **health care financing** shaped distinctive Japanese patterns of elderly care provision. The financing system provided a hidden subsidy--through national health insurance coverage of long-term hospitalization--that encouraged high institutionalization rates of elderly in medical facilities. Public financing for long-term elderly hospitalization, however, has not been matched by government attention to quality of care, resulting in serious quality problems and reflecting a social trade-off between cost and quality. Also, until recently the financing system rarely reimbursed home health care, thereby creating strong disincentives to the development of formal home health care services. This analysis has important implications for reforms now being considered by the Japanese government in the financing and provision of health care for the elderly, especially the limitations of relying on reimbursement price policy. The reforms could have unintended negative consequences for equity, efficiency, and quality of care.

TI Alcohol-related hospitalizations of elderly people. Prevalence and geographic variation in the United States.
SO JAMA 1993 Sep 8;270(10):1222-5
JT JAMA
AD Department of Medicine, Medical College of Wisconsin, Milwaukee.
LA Eng
AB OBJECTIVE--To determine the prevalence, geographic variation, and charges to Medicare of alcohol-related hospitalizations among elderly people in the United States. DESIGN--A cross-sectional prevalence study using 1989 hospital claims data from the **Health Care Financing** Administration (HCFA). Rates were determined using (1) hospital claims records from the HCFA's Medicare Provider Analysis and Review Record (MEDPAR) database for all Medicare Part A beneficiaries aged 65 years and older; (2) county population estimates for 1985 from the Bureau of the Census; and (3) per capita consumption of alcohol by state in 1989 as estimated by the US Department of Health and Human Services.

SETTING--Data include all hospital inpatient Medicare Part A beneficiaries aged 65 years and older in the United States in 1989. RESULTS--The prevalence of alcohol-related hospitalizations among people aged 65 years and older nationally in 1989 was 54.7 per 10,000 population for men and 14.8 per 10,000 for women. Comparison with hospital records showed that MEDPAR data had a sensitivity of 77% to detect alcohol-related hospitalizations. There was considerable geographic variation; prevalence ranged from 18.9 per 10,000 in Arkansas to 77.0 per 10,000 in Alaska. A strong correlation existed between alcohol-related hospitalizations and per capita consumption of alcohol by state (Spearman correlation coefficient, .64; $P < .0001$). In 1989, the hospital-associated charges to Medicare for all admissions where the primary diagnosis was alcohol related ($N = 33,039$) totaled \$233,543,500. Median charge per hospital stay was \$4514. CONCLUSIONS--Alcohol-related hospitalizations among elderly people are common; rates were similar to those for myocardial infarction as detected by the same method. The charges to Medicare for this preventable problem are considerable. Ecological analysis suggests that per capita consumption in the total US population predicts alcohol-related hospitalizations in the elderly population.

TI The resource-based relative value scale: methods, results and impacts on urology.
SO J Urol 1993 Sep;150(3):981-7
JT JOURNAL OF UROLOGY
AD Department of Surgery, University of California, Los Angeles.
LA Eng
AB Increased concern for rising health care costs in the United States has led to the passage of legislation to reform physician payment for Medicare services based on resource inputs. In January 1992 the **Health Care Financing** Administration began implementing the new law, which replaces the existing Medicare system of physician payment with a fee schedule based on the resource-based relative value scale (RBRVS). We summarize the methods and data used to derive the RBRVS for urology. A national random sample of 115 practicing urologists completed structured telephone surveys to provide ratings of physician time and work required before, during and after most frequently performed urological services. Subsequent survey cycles with urologists provided further refinement. Urologists then participated in a cross-specialty physician panel to link services from all specialties onto a common scale. This common scale was adjusted for geographic differences in practice overhead costs and malpractice insurance premiums. A monetary conversion factor, determined by the **Health Care Financing**

Administration, was then applied to convert the RBRVS into a Medicare fee schedule. The merits and demerits of the scientific process used to develop and maintain the relative value scale are extensive. While statistically valid and reproducible, the study results have been altered in the political arena. The results and impacts of the new Medicare payment system on urology will be significant, although it is not yet clear how urological practice will be affected. Although faring better than most surgical specialties, urologists stand to lose approximately 8% of their Medicare income when the new fee schedule is fully implemented. There will be relative gains for evaluation and management services and losses for most invasive procedures.

TI A critique of the practice-expense values of the resource-based relative value scale [see comments]
SO J Fam Pract 1993 Jul;37(1):57-67
JT JOURNAL OF FAMILY PRACTICE
LA Eng
AB The resource-based relative value scale (RBRVS) was implemented by the **Health Care Financing** Administration on January 1, 1992. The practice-expense payments from the old Medicare fee scale were moved unchanged into RBRVS. This resulted in underpayment of office-based practice expenses and overpayment of hospital-based practice expenses. For example, office visits are underpaid by \$10.28, whereas coronary angiograms are overpaid by \$123.00. Unpaid practice expenses reduce the after-expense physician-work fee of the average office visit by about one half, yet overpayment of practice expenses for some hospital procedures almost doubles the after-expense physician-work fee for some subspecialties. Inflation will likely increase the actual practice expense of the average office visit to the point that the after-expense physician-work fee for the family physician will be reduced to zero by the year 2001.

JT MMWR. MORBIDITY AND MORTALITY WEEKLY REPORT
LA Eng
AB Pneumonia and influenza (P&I) are the sixth leading cause of death in the United States, and persons aged > or = 65 years and persons with chronic conditions (e.g., lung or heart disease, diabetes, or cancer) are at greatest risk for P&I. During major epidemics, hospitalization rates for persons at highest risk may increase twofold to fivefold. However, only 30% of persons aged > or = 65 years responding to CDC's National Health Interview Survey for 1989 reported having received the influenza vaccine during the previous year. In 1988, the **Health Care Financing** Administration (HCFA) and CDC began a congressionally mandated 4-year demonstration project to evaluate the cost-effectiveness to Medicare of providing influenza vaccine to Medicare beneficiaries. This report presents final results of the Medicare Influenza Vaccine Demonstration conducted during 1988-1992.

LA Eng
AB The National Cancer Institute and the **Health Care Financing** Administration share a strong research interest in cancer costs, access to cancer prevention and treatment services, and cancer patient outcomes. To develop a database for such research, the two agencies have undertaken a collaborative effort to link Medicare Program data with the Surveillance, Epidemiology, and End Results (SEER) Program database. The SEER Program is a system of 9 population-based tumor registries that collect standardized clinical information on cases diagnosed in separate, geographically defined areas covering approximately 10% of the US population. Using a deterministic matching algorithm, the records of 94% of SEER registry cases diagnosed at age 65 or older between 1973 to 1989, or more than 610,000 persons, were successfully linked with Medicare claims files. The resulting database, combining clinical characteristics with information on utilization and costs, will permit the investigation of the contribution of various patient and health care setting factors to treatment patterns, costs, and medical outcomes.

 AB As part of a small-area analysis of carotid endarterectomy (CE) surgery,
 this review of Medicare claims data for a 26-month period addresses
 variations in surgical volume, mortality, readmissions, and charges. A
 surprisingly high percentage of surgeons performing CE did few
 procedures, and surgical volume appeared to be associated with higher
 mortality and charges. The implications of these data for both hospital
 credentialing committees and management and for purchasers and consumers
 of care, as well as the ways in which the **Health Care Financing**
 Organization's (HCFA) Health Care Quality Improvement Initiative (HCQII)
 will reorder their relationships with peer review organizations (PROs),
 are discussed. This study is useful in addressing the potential of
 efforts by PROs to increase the quality of care under the HCQII.

TI Mortality in a public and a private hospital compared: the severity of antecedent disorders in Medicare patients.
SO Am J Public Health 1993 Jul;83(7):966-71
JT AMERICAN JOURNAL OF PUBLIC HEALTH
AD Memphis Veterans Affairs Medical Center, TN.
LA Eng
AB OBJECTIVES. The objectives of this study were to determine (1) if there were significant differences between patients who died at a public hospital and those who died at a university hospital that functions as a private, community hospital, and (2) if those differences were associated with an increased risk of death. METHODS. Chart review collected variables used by the **Health Care Financing** Administration in mortality analyses to examine how severity of illness data contribute to accurate predictions of death in a public hospital compared with a university hospital. RESULTS. Compared with patients who died at the university hospital, public hospital patients who died had more comorbid disease, were more severely ill, more likely to be emergently admitted, and more likely to be admitted from an extended-care facility. Inclusion of severity of illness with variables previously used to predict mortality significantly improved the accuracy of mortality prediction models for the public hospital but not for the university hospital. CONCLUSIONS. The results suggest that urban public hospitals provide care to more severely ill patients. Administrative data sets may not be adequate to identify these differences between patient populations.

AB On December 16, 1991, Senator Harris Wofford invited the president of the University of Pittsburgh Medical Center to convene a group of its leaders for a roundtable discussion of health care issues. At that meeting, J. Dennis O'Connor, Ph.D., chancellor of the University of Pittsburgh, offered to appoint a multidisciplinary group of people from western Pennsylvania to collect data to analyze future policy options relative to health care and make its findings available to the senator, other legislators, and health policy makers. The chancellor invited representatives from the community, the University of Pittsburgh Medical Center, the University's Faculty of Arts and Sciences, and other academic and health care institutions in the area to participate in the analytical process. The task force met frequently over a 10-month period to develop a report, a portion of which is excerpted here.

TI Restructuring American **health care financing**: first of all, do no harm!
SO Hepatology 1993 Jul;18(1):206-15
JT HEPATOLOGY
LA Eng
AB Health care costs are climbing throughout the western world. Aging populations and the costs of advanced technology are the principal forces behind much of this global increase. No country has yet succeeded in containing these growing costs other than by some form of rationing. A variety of experimental strategies, including managed competition, are being considered or tested, but none is clearly effective. American health care expenditures differ, not in that they are rising, but in their enormously high starting point. Among other things, our higher costs reflect administrative costs of more than 20%, double those of Canada and nearly triple the European average; a malpractice system that, whatever its possible advantages, costs more than 10 times as much as it pays out to the injured; the enormous medical costs of poverty; maldistribution of physician specialties and incomes; and reimbursement systems that eliminate consumer input and oversight. Restructuring the system of **health care financing** to bring administrative costs in line with those of other nations could save at least \$70 billion annually; another \$25 billion or more could be saved by replacing the malpractice system with more cost-effective alternatives. These savings could defray the costs of insuring all those not now covered, without increasing either costs to the middle class, through taxation of benefits, or total health care expenditures. With all Americans covered, the necessary restructuring of the system of health care delivery could be conducted without the current pressure for immediate drastic reform, which carries with it the risk of serious

error. In dealing with the sick, physicians are taught to apply two maxims: "primum non nocere" or "first of all, do no harm!"; and the rule of therapeutic restraint. The latter states that a severe chronic illness may respond better, and with fewer complications, to gradual corrective measures than to highly aggressive therapy. Both rules could well be applied to curing the American health care system.

TI Medicaid: taking stock.
SO J Health Polit Policy Law 1993 Spring;18(1):43-66; discussion 67-74
JT JOURNAL OF HEALTH POLITICS, POLICY AND LAW
AD Boston University.
LA Eng
AB In the last few years, Medicaid has attracted more than casual

attention, one reflection of which is the fact that JHPPL has published five papers on the program in its last few issues. This paper, a sixth, takes a broader view of the program than is typically the case. After a critique of the five recent articles, I discuss several questions raised by them and reach the following conclusions: First, the states do not invest enough in producing program data suitable for policy analysis and research. One lesson: Better data and analysis can help the states to avoid expensive mistakes. Second, those policy analyses that have been offered fail to give sufficient attention to the political dimension of policy. That is one reason why policy choices produce unexpected effects. Third, since Medicaid is a relatively small player in the vast medical care market, incentives adopted by Medicaid officials throughout the country rarely have the desired effects. Finally, as long as Medicaid remains the principal mechanism to provide access to health care for the poor, it must be made as efficient and effective as possible. Yet, for both political and economic reasons, Medicaid can never be what its original planners had hoped, the vehicle for providing the poor with reliable access to mainstream medical care.

TI Race and sex differences in associations of vegetables, fruits, and carotenoids with lung cancer risk in New Jersey (United States).
SO Cancer Causes Control 1993 May;4(3):273-81

JT CANCER CAUSES AND CONTROL

AD Division of Cancer Prevention and Control, National Cancer Institute,
Bethesda, MD 20892.

LA Eng

AB We used data from a case-control study conducted in New Jersey between 1980 and 1983 to evaluate race and sex differences in associations of vegetable, fruit, and carotenoid consumption with lung cancer. Cases included 736 White males, 860 White females, 269 Black males, and 86 Black females with incident, histologically confirmed, primary cancer of the trachea, bronchus, or lung. Controls were identified through drivers' license and **Health Care Financing** Administration files and included 548 White males, 473 White females, 170 Black males, and 47 Black females. Usual intakes of vegetables (predominantly yellow/green) and fruit (predominantly yellow/orange) as well as other food sources of carotenoids were ascertained by a food frequency questionnaire. White females showed significant inverse associations of lung cancer with vegetables, fruit, and carotenoids. White males showed nonsignificant inverse associations with vegetables and carotenoids, and Black females just with vegetables. No inverse associations were found for Black males. Vegetable consumption was associated with risk of all histologic types of lung cancer, but the pattern of increasing risk with decreasing intake was limited to smokers. We infer that consumption of yellow/green vegetables and carotenoids may confer protection from lung cancer to White male and White female smokers. Further studies are needed to clarify the effect in Blacks.

TI Hidden problems in current **health-care financing** and potential changes.

SO Am Psychol 1993 Mar;48(3):261-4

JT AMERICAN PSYCHOLOGIST

AD University of Nebraska Medical Center, Omaha 68105.

LA Eng

AB Health-care costs in the United States have risen significantly in the past 10 years, markedly affecting access to quality medical and mental health care. Deficit financing of our federal health-care expenditures adds billions of dollars annually to our national debt. Health-care reform is being hindered by both the inability of the government to pay for the uninsured and the unremitting spiral of the Medicare and Medicaid entitlement programs. The reasons for the total health-care cost increases include higher provider charges, overutilization of services, and the burgeoning technology; problems of malpractice, overspecialization, and consumer demands have also fueled the higher costs.

JT INQUIRY

AD Gerontology Center, University of Massachusetts, Boston 02125-3393.

LA Eng

AB Over the past few years, a number of HMOs have chosen to discontinue their Medicare risk contracts. Using logistic regression, this study sought to identify factors associated with Medicare risk contract market exit in 1988. Low AAPCC rates were found to systematically affect the market exit of only Medicare risk contractors that were regional components of a central HMO organization. The Medicare risk market exit of other HMOs was found to be principally related to two attributes

suggestive of possible unfavorable risk selection: the dropping of a previously offered prescription drug benefit and higher proportions of categorically disabled Medicare enrollees.

TI Rehospitalizations after coronary revascularization among Medicare beneficiaries.
SO Am J Cardiol 1993 Jul 1;72(1):26-30
JT AMERICAN JOURNAL OF CARDIOLOGY
AD **Health Care Financing** Administration Office of Research and Demonstrations, Baltimore, MD 21207.
LA Eng
AB The rehospitalization experience of Medicare beneficiaries undergoing coronary artery bypass surgery or percutaneous transluminal coronary angioplasty in 1986 and 1987 was studied by following 53,715 patients who underwent coronary artery bypass and 28,817 patients who underwent angioplasty for 1 year using Medicare hospital claims data. The 1-year rehospitalization rate after bypass and angioplasty was 629 and 863 per 1,000, respectively, compared to a rate of 607 for the Medicare patient population in general. About 45% of rehospitalizations after bypass and two thirds after angioplasty were in categories determined by an expert panel to be possibly related to the original procedure. After angioplasty, there were 61 discharges per 1,000 for bypass surgery and 140 per 1,000 for a repeat angioplasty. Rehospitalization rates for coronary artery bypass surgery after angioplasty were significantly lower for female and black patients who underwent angioplasty. The

volume of rehospitalization after revascularizations makes it an important outcome measure. Medicare administrative records provide a unique source of information on rehospitalizations and make possible the monitoring of broad trends in the frequency and outcomes of coronary revascularization. The lower rates of bypass surgery after angioplasty for black and female patients are in line with other studies and bear further investigation.

JT JOURNAL OF INFECTIOUS DISEASES
AD Hepatitis Branch (World Health Organization Collaborating Centre for Research and Reference in Viral Hepatitis, Centers for Disease Control and Prevention, Atlanta, Georgia 30333.
LA Eng
AB Liver disease caused by hepatotropic viruses imposes a substantial burden on health care resources. Persistent infections from hepatitis B virus (HBV), hepatitis C virus, and hepatitis delta virus result in chronic liver disease, while hepatitis A virus and hepatitis E virus produce a self-limited disease. Effective hepatitis B vaccines that provide long-term protection against chronic HBV infection have been available for > 10 years, while inactivated hepatitis A vaccines have recently been shown to prevent acute disease. To prevent transmission

of HBV, scientifically and epidemiologically sound recommendations call for vaccination of all infants in successive birth cohorts worldwide. For hepatitis A vaccines, recommendations will be developed in the near future and should reflect vaccine performance and the epidemiology of hepatitis A. A number of policy, **health care financing**, and educational issues must be addressed to ensure the effective use of both of these vaccines.

TI Defining rural hospital markets.
SO Health Serv Res 1993 Jun;28(2):183-200
JT HEALTH SERVICES RESEARCH
AD Office of Research, **Health Care Financing** Administration (HCFA), Baltimore, MD 21207.
LA Eng
AB OBJECTIVE. The purpose of this study is to examine the geographic scope of rural hospital markets. DATA SOURCES. The study uses 1988 Medicare patient discharge records (MedPAR) and hospital financial information (HCRIS) for all rural hospitals participating in the Medicare Program. STUDY DESIGN. Hospital-specific market areas are compared to county-based market areas using a series of geographic and socioeconomic-demographic dimensions as well as indicators of market competitiveness. The potential impact of alternative market configurations on health services research is explored by estimating a model of rural hospital closure. DATA COLLECTION/EXTRACTION METHODS. Hospital-specific market areas were defined using the zip code of patient origin. Zip code-level data were subsequently aggregated to the market level. FINDINGS. Using the county as the hospital market area results not only in the inclusion of areas from which the hospital does not draw patients but also in the exclusion of areas from which it does draw patients. The empirical estimation of a model of rural hospital closure shows that the definition of a hospital market area does not jeopardize the ability to identify major risk factors for closure. CONCLUSIONS. Market area definition may be key to identifying and monitoring populations at risk from rural hospital decisions to downsize or close their facilities. Further research into the market areas of

rural hospitals that have closed would help to develop alternative, and perhaps more relevant, definitions of the population at risk.

SO Hosp Community Psychiatry 1993 Jun;44(6):545-6
JT HOSPITAL AND COMMUNITY PSYCHIATRY
AD Department of Psychiatry, University of Southern California, School of Medicine, Los Angeles 90033.
LA Eng
AB People with chronic mental illness present complex challenges for the design of **health care financing** reforms. In this position statement from the committee on psychiatry and community of the Group for the Advancement of Psychiatry, the authors describe chronic and severe mental illnesses as psychiatric illnesses that require acute and ongoing

psychiatric assessment and treatment, as chronic medical diseases that require ongoing rehabilitative services, and as persistent disabilities that need ongoing supportive care and social services. Any proposal for health care reform must ensure parity of chronic psychiatric illnesses with other psychiatric conditions. It must also reimburse psychiatric rehabilitation at parity with other medical rehabilitation and provide equal access to and reimbursement for broad ancillary health services that reduce costs and improve quality of life.

TI The use of standardized indicators as quality improvement tools: an application in Pennsylvania nursing homes.

SO Am J Med Qual 1993 Summer;8(2):72-8

JT AMERICAN JOURNAL OF MEDICAL QUALITY

AD Department of Health Administration, Temple University, Philadelphia, PA 19122.

LA Eng

AB The Institute of Medicine recommends the use of key quality indicators (resident outcomes that suggest the presence of good or bad care) as tools for interfacility comparison of the quality of care provided in nursing homes. In the spirit of this recommendation, the **Health Care Financing** Administration released selected results from its Medicare and Medicaid Annual Certification Survey to guide consumers in purchasing nursing home services. However, because this information is published without adjustment for resident characteristics that can influence the outcomes of nursing home care, its utility for policy-makers or consumers interested in variation in nursing home quality is limited. This research study utilizes federal and state survey data to evaluate variations in mortality, pressure ulcers, urethral catheterization, and physical restraint use in 438 Medicare-certified skilled nursing care facilities in Pennsylvania. A standardization function adjusting for resident characteristics known to influence outcomes is developed and estimated by ordinary least squares regression. Results suggest considerable variation in rates for these indicators across Pennsylvania nursing home facilities. Alternative uses for risk-adjusted key quality indicators as tools for improving nursing home quality and assisting potential consumers of nursing home care in making better informed choices are considered.

 TI Border crossing for hospital care and its implications for the use of
 statewide data.
 SO Soc Sci Med 1993 Jun;36(11):1455-65
 JT SOCIAL SCIENCE AND MEDICINE
 AD Institute for Health Policy Studies, University of California, San
 Francisco 94109.
 LA Eng
 AB A major concern of researchers using state data sets for
 population-based analyses and market share studies in the health care
 sector is the potential bias caused by 'border crossing'--patients
 receiving care out of state. By using the **Health Care Financing**
 Administration (HCFA) discharge abstract files for 1987 and 1988, we
 found that 'border crossing' is not a serious problem for the two large
 states we examined. Only 4.4% of New York patients and 2.15% of
 California patients received care out of state. At the county and zip
 code level, 'border crossing' is more frequent but tends to be
 concentrated in areas adjacent to other states. Even excluding all zips
 with more than 10% of patients crossing the 'border' results in a small
 loss of patients (2.2% for New York and 1.0% for California).

JT HEALTH AFFAIRS
AD Office of the Actuary, **Health Care Financing** Administration, Baltimore.
LA Eng
AB The United States spent \$751.8 billion on health in 1991, an increase of 11.4 percent over 1990 levels. National health expenditures consumed 13.2 percent of gross domestic product (GDP). The 11.4 percent growth rate in spending is four times the rate of growth in the general economy. Medicaid contributed substantially to overall spending in 1991. Consumers' out-of-pocket payments grew only 5.7 percent to a total of \$144.3 billion, accounting for 19.2 percent of national health expenditures (the lowest share ever reported). Economywide price inflation accounted for 36 percent of health spending growth in 1991; increases in use and intensity of health services accounted for 30 percent of total spending growth; excess medical price inflation accounted for 25 percent, an amount that is consistent with its share throughout the 1980s.

JT HEALTH AFFAIRS
AD Rural Health Research Center, School of Public Health, University of
Minnesota.
LA Eng
AB Rural hospitals continue to face the threat of closure. Congress passed
legislation in 1989 and 1990 to offer an alternative for small rural
hospitals; the legislation encourages hospitals to form networks
comprising an essential access community hospital (EACH) and one or more
rural primary care hospitals. This legislation is a tightly focused
program that will affect no more than an estimated 150 hospitals in
seven states; implementation of the program has been controversial, as
this DataWatch demonstrates. The authors describe the profile of rural
hospitals that are likely to apply to participate in the program, based
on distances between hospitals and number of beds.

JT HEALTH AFFAIRS
AD Office of National Health Statistics, **Health Care Financing**
Administration, Baltimore.
LA Eng
AB The effectiveness of proposed changes to the Medicare program depends on consumers' responses to different market incentives, which vary according to the coverage the elderly possess to supplement their Medicare coverage. This Data Watch explores the extent of supplemental insurance among the elderly, based on a new data set from the Medicare Current Beneficiary Survey. Only 11 percent of Medicare beneficiaries have only Medicare as their source of coverage; the rest of the elderly population is covered by either private coverage (employer-sponsored retiree coverage or individually purchased coverage) or Medicaid. An increase in Medicare cost sharing would likely affect one-third of elderly beneficiaries, which calls into question the effectiveness of this approach to Medicare program reform.

Jersey-Robert Wood Johnson Medical School, New Brunswick 08903.
LA Eng
AB Differences in the quality of medical care provided to black and white
patients have been observed in the United States, but have not been
studied in dialysis patients. We examined whether dialysis delivery, as
measured by indirect determination of Kt/V, differs between black and
white patients in New Jersey. Five hundred forty-four patients at 10
New Jersey dialysis units were randomly selected by the US **Health Care
Financing** Administration as part of their Medical Case Review Study.
Of these, 237 patients at eight units were classified as black or white
and had urea kinetic data available. The mean Kt/V urea was higher for
white than black patients at all facilities, averaging 1.03 for the 123
black patients and 1.20 for the 114 white patients (P = 0.0006). Black
patients were 40% more likely than white patients to have a Kt/V less
than 1.0 (45.6% of black patients v 32.5% of white patients, P = 0.038).
Racial disparities in dialysis delivery exist, the causes and
consequences of which need to be addressed.

TI Questions and answers about managed competition.
SO Int J Health Serv 1993;23(2):213-8
JT INTERNATIONAL JOURNAL OF HEALTH SERVICES
AD Center for National Health Program Studies, Cambridge Hospital, MA 02139.
LA Eng
AB The Managed Competition strategy for **health care financing** reform would push most people into cut-rate versions of health maintenance organizations chosen for them by their employer and owned by an insurance company. Many of those who currently enjoy good coverage would be forced into bare bones plans, and would forfeit the right to choose their health care provider. There is little evidence that the rigidly multi-tiered system created by Managed Competition would be more efficient or less expensive than the current U.S. system, and administrative costs would likely rise. Promises to expand coverage for the uninsured are likely to fall by the wayside if cost containment

fails, and no current Managed Competition proposals address long-term care. In rural areas including at least 30 percent of the U.S. population, price competition central to the Managed Competition strategy is untenable since a long hospital or other provider cannot compete with itself. Managed Competition would empower vertically integrated corporate health care insurer/providers and disempower patients and the clinical work force.

TI Atopic dermatitis in children: who cares? Who pays?
 SO J Am Acad Dermatol 1993 May;28(5 Pt 1):699-703
 JT JOURNAL OF THE AMERICAN ACADEMY OF DERMATOLOGY
 AD Department of Pediatrics, Children's Hospital of Philadelphia,
 Pennsylvania.
 LA Eng
 AB BACKGROUND: Atopic dermatitis is an important cause of morbidity in
 children of all ages. Despite its high prevalence, there has been no
 examination of ways in which care for atopic dermatitis is delivered.
 OBJECTIVE: This study reviewed the costs for care of childhood atopic
 dermatitis in an urban setting and estimated the national cost for
 treatment of the disease. METHODS: We used data from one children's
 hospital to study the use of the emergency room for atopic dermatitis
 and used national data sets to estimate the cost of care in the United
 States. RESULTS: A large proportion of visits occur in the emergency
 department, during daytime office hours, and mostly by patients who have
 public insurance. The total national cost for treatment of childhood
 atopic dermatitis is \$364 million annually, which is a conservative
 estimate. CONCLUSION: Given its high prevalence, associated morbidity,
 and cost, resources must be better allocated to improve the organization
 of care for patients with atopic dermatitis.

TI Racial differences in the use of revascularization procedures after coronary angiography.

SO JAMA 1993 May 26;269(20):2642-6

JT JAMA

AD Division of General Medicine, Brigham and Women's Hospital, Boston, MA.

LA Eng

AB OBJECTIVE--To assess whether rates of coronary revascularization procedures differ between blacks and whites after coronary angiography is performed and to assess the relationship of these rates to hospital characteristics. DESIGN--A retrospective cohort study using 1987 and 1988 data on hospital claims and characteristics from the **Health Care Financing** Administration. SETTING--One thousand four hundred twenty-nine acute care hospitals that provide coronary angiography in the United States. PATIENTS--A national sample of 27,485 Medicare Part A enrollees, aged 65 to 74 years, who underwent inpatient angiography for coronary heart disease in 1987. MAIN OUTCOME MEASURE--The adjusted odds of revascularization with either coronary angioplasty or bypass graft surgery within 90 days of angiography for whites relative to blacks, controlling for age, sex, region, Medicaid eligibility, principal diagnosis, comorbid diagnoses, and hospital characteristics of ownership, teaching status, urban/suburban or rural location, and availability of revascularization procedures. RESULTS--White men and women were significantly more likely than black men and women, respectively, to receive a revascularization procedure after coronary angiography (57% and 50% vs 40% and 34%, both $P < .001$). The adjusted odds of receiving a revascularization procedure after coronary angiography were 78% higher for whites than blacks (95% confidence interval for odds ratio, 1.56 to 2.03). Statistically significant racial differences in the adjusted odds of receiving a revascularization procedure were present in all types of hospitals except rural hospitals, and these differences did not vary significantly by any of the four hospital characteristics (all $P > .20$ for interaction terms). CONCLUSIONS--Among Medicare enrollees, whites are more likely than blacks to receive revascularization procedures after coronary angiography. Racial differences of similar magnitude occur in all types of hospitals. These differences may reflect overuse in whites or underuse in blacks, but they are unlikely to reflect access to cardiologists or hospitals that perform revascularization procedures. Potential explanations include unmeasured clinical or socioeconomic factors, differing patient preferences, and racial bias at the hospitals performing angiography.

TI Effects of lower surgical fees on the use of physician services under Medicare [see comments]
SO JAMA 1993 May 19;269(19):2513-8
JT JAMA
AD Department of Medicine, University of Pennsylvania, Philadelphia.
LA Eng
AB BACKGROUND AND OBJECTIVE--The changes in physician fees that will occur under the resource-based Medicare Fee Schedule (MFS) are similar to those that took place under the Omnibus Budget Reconciliation Act of 1987 (OBRA 87), when Medicare fees for selected "overpriced" procedures and diagnostic tests were reduced. To gain insight regarding the changes in utilization that may occur under the MFS, this study examines the effects of the OBRA 87 fee reductions on the use of physician services by Medicare patients. DATA AND METHODS--The five specialties that were most affected by the OBRA 87 fee reductions were studied: ophthalmology, thoracic surgery, urology, orthopedic surgery, and gastroenterology. Medicare physician claims files for 1987 and 1989 were used to obtain data on utilization and fees. Multivariate regression analysis was used to assess the effect of changes in fees on changes in utilization. RESULTS--The best estimate of the effect of the OBRA 87 fee reductions on overall physician-services utilization, obtained by pooling the five study specialties, was that every 1% decrease in fees led to a 0.09% decrease in the volume and complexity of services (95% confidence interval, 0.49% decrease to 0.31% increase). This result was not sensitive to minor changes in the covariates included in the regression model. CONCLUSION--To calculate payment levels during the transition to the MFS, the **Health Care Financing** Administration assumed that physicians whose Medicare revenue declines under the MFS will increase service volume and complexity enough to make up one half of the lost revenue. The findings of this study suggest that the **Health Care Financing** Administration's assumption was, at best, extreme.

TI A model for technology assessment applied to pulse oximetry. The Technology Assessment Task Force of the Society of Critical Care Medicine.

SO Crit Care Med 1993 Apr;21(4):615-24

JT CRITICAL CARE MEDICINE

LA Eng

AB OBJECTIVES: To test a model for the assessment of critical care technology. To develop practice guidelines for the use of pulse oximetry. DATA SOURCES: A computer-assisted search of the English language literature and interviews with recognized experts in the field of pulse oximetry. STUDY SELECTION: Those studies that addressed one or more of the seven questions contained in our technology assessment template were analyzed. Study design was not a factor in article selection. However, the lack of well-designed clinical outcome studies was an important factor in determining the method of practice policy development we utilized. DATA EXTRACTION: A focus person summarized the data from the selected studies that related to each of the seven assessment questions. The preliminary data summary developed by the focus person was further analyzed and refined by the task force and then sent to 16 expert reviewers for comment. These expert comments were considered by the task force, and this final consensus report was developed. DATA SYNTHESIS: Pulse oximetry combines the principles of spectrophotometry and plethysmography to noninvasively measure oxygen saturation with a high degree of accuracy over the range of 80% to 100% saturation, assuming the device is being used according to the manufacturer's instructions and without any adverse operating conditions. The appropriate clinical uses of pulse oximetry fall into one of two broad categories: as a warning system based on continuous real-time measurement of arterial desaturation, or as an end-point for titration of therapeutic interventions. There are no published studies that allow for definitive, outcome-based conclusions concerning either the clinical impact or cost-benefit ratio of pulse oximetry. CONCLUSIONS: The model developed for technology assessment proved to be appropriate for assessing pulse oximetry. The available data have allowed us to develop an evidence-based practice policy for the use of pulse oximetry in critical care. Critical care clinicians, researchers, and industry have a shared responsibility to provide valid outcome and efficacy studies of new technologies.

TI The detection of problem analytes in a single proficiency test challenge in the absence of the **Health Care Financing** Administration rule violations.
SO Arch Pathol Lab Med 1993 Apr;117(4):437-43
JT ARCHIVES OF PATHOLOGY AND LABORATORY MEDICINE
AD Park Nicollet Medical Center, Minneapolis, Minn. 55416.
LA Eng
AB The Clinical Laboratory Improvement Act of 1988 (CLIA 88) has dramatically changed proficiency testing (PT) practices having mandated (1) satisfactory PT for certain analytes as a condition of laboratory operation, (2) fixed PT limits for many of these "regulated" analytes, and (3) an increased number of PT specimens (n = 5) for each testing cycle. For many of these analytes, the fixed limits are much broader than the previously employed Standard Deviation Index (SDI) criteria. Paradoxically, there may be less incentive to identify and evaluate analytically significant outliers to improve the analytical process. Previously described "control rules" to evaluate these PT results are unworkable as they consider only two or three results. We used Monte Carlo simulations of Kodak Ektachem analyzers participating in PT to determine optimal control rules for the identification of PT results that are inconsistent with those from other laboratories using the same methods. The analysis of three representative analytes, potassium, creatine kinase, and iron was simulated with varying intrainstrument and interinstrument standard deviations (si and sg, respectively) obtained from the College of American Pathologists (Northfield, Ill) Quality Assurance Services data and Proficiency Test data, respectively. Analytical errors were simulated in each of the analytes and evaluated in terms of multiples of the interlaboratory SDI. Simple control rules for detecting systematic and random error were evaluated with power function graphs, graphs of probability of error detected vs magnitude of error. Based on the simulation results, we recommend screening all analytes for the occurrence of two or more observations exceeding the

same +/- 1 SDI limit. For any analyte satisfying this condition, the mean of the observations should be calculated. For analytes with sg/si ratios between 1.0 and 1.5, a significant systematic error is signaled by the mean exceeding 1.0 SDI. Significant random error is signaled by one observation exceeding the +/- 3-SDI limit or the range of the observations exceeding 4 SDIs. For analytes with higher sg/si, significant systematic or random error is signaled by violation of the screening rule (having at least two observations exceeding the same +/- 1 SDI limit). Random error can also be signaled by one observation exceeding the +/- 1.5-SDI limit or the range of the observations exceeding 3 SDIs. We present a practical approach to the workup of apparent PT errors.

TI Quality of care problems among Medicare patients in New York State.
SO N Y State J Med 1993 Mar;93(3):159-62
JT NEW YORK STATE JOURNAL OF MEDICINE
AD Island Peer Review Organization (IPRO), Lake Success, NY 11042.
LA Eng
AB The Island Peer Review Organization is the peer review organization in New York State and is under contract with the **Health Care Financing** Administration to monitor the quality of care rendered to Medicare patients. A severity level III is assigned when a confirmed quality problem with significant adverse effects for the patient is confirmed. A severity level II is assigned when a confirmed quality problem with the potential for significant adverse effects on the patient is found. The purpose of this study was to retrospectively analyze all 85 severity level III citations and a 12% (223) random sample of the 1,880 severity level II citations for 1991. Another objective was to characterize the providers involved in each of these two levels of quality of care problems. Among the 85 severity level III citations, 34 (40.0%) involved premature death and 33 (38.8%) readmission. Treatment (45.0%), diagnostic (16.9%), and monitoring (16.4%) problems accounted for 78.3% of the 189 problems identified in severity level III citations. The

leading problem areas were the treatment of infections and the use of antibiotics (21.2%), fluid and electrolyte management (21.2%), drug use (9.4%), the use of endotracheal tubes (5.9%), the management of diabetes mellitus (5.9%), and the management of hematologic disorders (5.9%). Attending physicians (65.9%), nursing departments (16.5%), and resident physicians (7.1%) were involved in the vast majority (89.5%) of severity level III citations. Treatment problems comprised 60.5% of the 243 problems found in severity level II citations, followed by inadequate work-up (20.2%), and incomplete documentation (12.3%).(ABSTRACT TRUNCATED AT 250 WORDS)

TI Trends in Medicare payments in the last year of life.
SO N Engl J Med 1993 Apr 15;328(15):1092-6
JT NEW ENGLAND JOURNAL OF MEDICINE
AD **Health Care Financing** Administration, Baltimore, MD 21207.
LA Eng
AB BACKGROUND. Increased attention is being paid to the amount and types of medical services rendered in the period before death. There is a popular impression that a greater share of resources is being devoted to dying patients than in the past. We examined trends in the proportion of Medicare expenditures for persons 65 years old or older in their last year of life to determine whether there were any changes from 1976 to 1988. METHODS. Using Medicare program data for 1976, 1980, 1985, and 1988, we classified Medicare payments according to whether they were made for people in their last year of life (decedents) or for survivors. We also assigned expenses for care in the last year of life according to intervals of 30 days before the person's death and examined trends according to age. RESULTS. Reflecting the large overall increase in Medicare spending, Medicare costs for decedents rose from \$3,488 per person-year in 1976 to \$13,316 in 1988. However, Medicare payments for decedents as a percentage of the total Medicare budget changed little, fluctuating between 27.2 and 30.6 percent during the study period. Payments for care during the last 60 days of life expressed as a percentage of payments for the last year also held steady at about 52 percent. Furthermore, the pattern of lower payments for older as

compared with younger decedents also prevailed throughout the study period. CONCLUSIONS. The same forces that have acted to increase overall Medicare expenditures have affected care for both decedents and survivors. There is no evidence that persons in the last year of life account for a larger share of Medicare expenditures than in earlier years.

TI The competition vogue and its outcomes.
SO Lancet 1993 Mar 27;341(8848):805-12
JT LANCET
AD New School for Social Research, Graduate School of Management and Urban Policy, New York, NY 10011.
LA Eng
AB Social security and comprehensive **health care financing** were developed to protect all citizens and to redistribute money to cover costs. Their inspiration was social solidarity rather than pecuniary self-interest. The United States differed from other countries by continuing a private market in health, with many self-centred and competing providers and insurers; and its prevailing school of health economics deplored the national health insurance and national health services that were universal in other countries and recommended devices that would eliminate "market failure" in health. When health economics grew in Europe during the 1970s and 1980s, the reformers' first presumption was that the voluminous American market-oriented literature must offer answers; but much of it proved superfluous, since European health care systems still had much competition and consumer choice, and they worked better than the reality in the United States. The United States itself has paid a heavy price for turning over health financing policy to the devotees of microeconomics and free markets, and today its serious problems in health are unsolved. So powerful is the pro-competitive ideology that it has now been adopted by the Democratic Clinton Administration, contradicting the heritage of Roosevelt, Truman, and Johnson.

TI Sole providers of hospital care in rural areas.
SO Inquiry 1993 Spring;30(1):34-40
JT INQUIRY
AD Office of Research, **Health Care Financing** Administration, Baltimore, MD 21207.
LA Eng
AB This study examines the possibility of developing alternative targeting criteria for identifying small rural hospitals that serve as the sole providers of hospital care in their market areas. Compared to facilities currently targeted under Medicare payment policies, high market share hospitals are larger, less isolated facilities that deliver more complex care to their patients than other rural hospitals. They do not appear to serve vulnerable patient populations. Most importantly, these facilities appear to be financially viable and are likely to continue to provide services to their patients. The results of the study suggest that appropriate targeting criteria for identifying essential access facilities for reimbursement policy should focus on both structural characteristics and utilization patterns.

TI Determination of lung cancer incidence in the elderly using Medicare claims data [see comments]
SO Am J Epidemiol 1993 Jan 15;137(2):226-34
JT AMERICAN JOURNAL OF EPIDEMIOLOGY
AD Epidemiology Branch, **Health Care Financing** Administration, Baltimore, MD.
LA Eng
AB The Surveillance, Epidemiology, and End Results (SEER) program of the National Cancer Institute provides data for making national estimates of lung cancer incidence and for monitoring secular trends. The authors compared the number of cases of lung cancer and the incidence rates among elderly residents of the five states included in the SEER program in 1986-1987 with the number of incident cases identified and the rates calculated using hospitalization and enrollment data on elderly Medicare beneficiaries maintained by the **Health Care Financing** Administration (HCFA) for the same years. The SEER program state registries identified 5.9% more cases than did HCFA ($p < 0.01$). However, the overall rates were similar (274.2/100,000 population for SEER and 264.7/100,000 population for HCFA), as were the majority of the rates for the different demographic subgroups examined. Age-adjusted lung cancer incidence rates for 1986 through 1990 among elderly Medicare beneficiaries residing outside of all nine SEER areas were 8-13 percent higher than the rates calculated for SEER-area residents. This observation is supported by the existence of similar differences in the age-adjusted lung cancer mortality rates for 1979 through 1988 in the same populations. Because the SEER areas may not be representative of the entire nation for lung cancer incidence and HCFA data cover the entire country, the authors recommend using HCFA information to complement the SEER data system.

 AB The authors survey the causes and results of introduction of DRG system.
 The main cause for the introduction of this system was the sudden rise
 of costs experienced in the early 80ties. The introduction was followed

by a manifest slowing down of cost rise, then again it started to increase a little. The internal efficiency of the institutions improved, the most outstanding example for that was the shortening of the average nursing time, the increase of the rate of outpatient consultations. The absolute value of costs did not decrease in spite of that because on the one hand medical technics are continuously developing and getting more expensive, on the other hand health care cannot as well be independent from the general processes of economy. Summarized it can be stated that the introduction of the DRG system in the USA did achieve its goal because it was able to slow down the rise of costs without serious operation disorders.

TI Healthcare reform: the role of coordinated critical care.
SO Crit Care Med 1993 Mar;21(3):457-64
JT CRITICAL CARE MEDICINE
AD Department of Surgery, University of Minnesota, Minneapolis.
LA Eng
AB OBJECTIVE: To evaluate and editorialize the evolving role of the discipline of critical care as a healthcare delivery system in the process of healthcare reform. DATA SOURCES: The sources included material from the Federal Office of Management and Budget, **Health Care Financing** Review, President Bush's Office, Association of American Medical Colleges, and publications of the Society of Critical Care Medicine. STUDY SELECTION: Data were selected that the author felt was relevant to the healthcare reform process and its implications for the discipline of critical care. DATA EXTRACTION: The data were extracted by the author to illustrate the forces behind healthcare reform, the implications for the practice of critical care, and role of critical care as a coordinated (managed) care system in the process of healthcare reform. DATA SYNTHESIS: Healthcare reform has been initiated because of a number of considerations that arise in evaluating the current healthcare delivery system: access, financing, cost, dissatisfactions with the mechanisms of delivery, and political issues. The reform process will occur with or without the involvement of critical care practitioners. Reforms may greatly alter the delivery of critical care services, education, training, and research in critical care. Critical care has evolved into a healthcare delivery system that provides services to patients who need and request them and provides these services in a coordinated (managed) care model. CONCLUSIONS: Critical care practitioners must become involved in the healthcare reform process, and critical care services that are effective must be preserved, as must the education, training, and research programs. Critical care as a healthcare delivery system utilizing a coordinated (managed) care model has the potential to provide services to all patients who need them and to deliver them in a manner that is cost effective and recognized as providing added value.

TI Vascular laboratory cost analysis and the impact of the Resource-Based Relative Value Scale payment system.
SO J Vasc Surg 1993 Feb;17(2):267-78; discussion 278-9
JT JOURNAL OF VASCULAR SURGERY
AD Section of Vascular Surgery, Dartmouth-Hitchcock Medical Center, Lebanon, NH 03756.
LA Eng
AB PURPOSE: This study compares the actual cost of performing noninvasive laboratory studies with reimbursement under the previous Medicare Part B system and under current resource-based relative value scale (RBRVS) guidelines. METHODS: We calculated the cost to operate our own laboratory and estimated national costs for small- and large-model laboratories. Reimbursement under Medicare Part B was calculated for each Current Procedural Terminology code from average Medicare reimbursement allowances and national case volumes in 1990, which were obtained from the **Health Care Financing** Administration. All data were expressed as dollars per hour of study time to allow universal comparison of costs and reimbursement among tests that require differing lengths of time for completion. RESULTS: Technical costs for laboratory time ranged from \$143 to \$173 per study hour. The largest components of laboratory expenses were fixed costs, including personnel (37% to 46%), equipment (30% to 42%), and facilities (6% to 8%). Variable costs such as billing (9% to 10%) accounted for most of the remainder. More efficient allocation of equipment resulted in lower costs in large laboratories, whereas continued use of depreciated equipment resulted in lower costs in our own laboratory (\$127/hr). CONCLUSIONS: We project that technical reimbursement under RBRVS will be \$82/hr nationally and \$80/hr locally, whereas global reimbursement (technical plus professional) will be \$116/hr and \$110/hr, respectively. On the basis of 1990 case volumes, the RBRVS system will decrease national global reimbursement by at least 35% compared with the previous Medicare Part B system. Under the new system, technical reimbursement will decrease by an estimated 27% nationally, whereas professional reimbursement will decrease by 52%. Revenue under RBRVS will not meet the cost to perform studies either nationally or locally. Technical reimbursement is 37% to 54% below actual technical costs, and even global reimbursement is 13% to 34% less than technical costs. Our analysis revealed that costs will exceed reimbursement despite maximization of operating efficiency. This analysis applies to outpatients only. A case mix including inpatients will further reduce reimbursement, because only the professional component is allowed. By setting reimbursement of vascular laboratories below actual costs, the new RBRVS system may ultimately reduce the availability of noninvasive vascular testing for elderly patients.

TI Serum albumin concentration-related **Health Care Financing**
Administration quality assurance criterion is method-dependent: revision
is necessary.
SO Am J Kidney Dis 1993 Feb;21(2):138-44
JT AMERICAN JOURNAL OF KIDNEY DISEASES
AD Northwest Kidney Centers, Laboratory of Pathology of Seattle, Inc., WA
98122.
LA Eng
AB The objective of this study was to examine quantitative differences
between the two commonly used methods for determining serum albumin
concentration, bromcresol green (BCG) and bromcresol purple (BCP), in
normal subjects and in 235 unselected dialysis patients in view of
recently established **Health Care Financing** Administration (HCFA)
quality assurance review criteria. The mean of normal results by the
BCG method was 4.4 g/dL, and 97.5% of values were 3.8 g/dL or higher.
The mean of normal results by the BCP method was 3.9 g/dL, and 97.5% of
values were 3.3 g/dL or higher. Serum albumin concentrations in samples
from the dialysis patients had respectively lower mean values by both
methods. For the BCG method, the mean was 3.8 g/dL, and 82% of values
were 3.5 g/dL or higher; for the BCP method, the mean was 3.3 g/dL, and
82% of values were 3.0 g/dL or higher. Likewise, for the reference
immunonephelometric procedure, the mean value for the dialysis patients
was 3.3 g/dL, and 82% of values were 3.0 g/dL or higher. For the
samples from the dialysis patients, in comparison with the
immunonephelometric method, the BCG method exhibited both constant
(intercept = 9.3 g/L) and proportional error (slope = 0.87). The mean
albumin value for the BCG method was 3.8 g/dL, 15% higher. In contrast,
the BCP method compared closely with the reference method: slope = 1.00,
intercept = 0.8 g/L, mean x = 3.3 g/dL, mean y = 3.3 g/dL. The HCFA
quality assurance criteria are valid only for the BCG method.(ABSTRACT

TI The relationship between adjusted hospital mortality and the results of peer review.
SO Health Serv Res 1993 Feb;27(6):765-77
JT HEALTH SERVICES RESEARCH
AD Division of Biostatistics/Clinical Epidemiology, Medical College of Wisconsin, Milwaukee 53226.
LA Eng
AB This study assessed the relationship between the **Health Care Financing** Administration adjusted mortality rate for a hospital and the errors in care found by the peer review process. The three data sets used were: (1) the 1987-1988 completed reviews from 38 peer review organizations (PROs) of 4,132 hospitals and 2,035,128 patients; (2) all 1987 hospital mortality rates for Medicare patients as adjusted by HCFA for patient mix; and (3) the 1986 American Hospital Association Survey. The PRO data were used to compute the percentage of cases reviewed from each hospital confirmed by a reviewing physician to have a quality problem. The average percentage of confirmed problems was 3.73 percent with state rates ranging from 0.03 percent to 38.5 percent. The average within-state correlation between the problem rate and the adjusted mortality rate for all PROs was .19 ($p < .0001$), but the correlations

were much higher for relatively homogeneous groups of hospitals, .42 for public hospitals and .36 for hospitals in large metropolitan statistical areas (MSAs). These results suggest that the HCFA adjusted hospital mortality rate and the PRO-confirmed problem rate are related methods to compare hospitals on the basis of quality of care. Both methods may compare quality better if used within a group of homogenous hospitals.

TI Effects of cognitive impairment on the reliability of geriatric assessments in nursing homes.
SO J Am Geriatr Soc 1993 Feb;41(2):136-42
JT JOURNAL OF THE AMERICAN GERIATRICS SOCIETY
AD Center for Social Research and Policy Analysis, Research Triangle Institute, Research Triangle Park, NC 27709.
LA Eng
AB OBJECTIVE: To explore the relationship between an elderly subject's cognitive status and the reliability of multidimensional assessment data. DESIGN: Survey, with cognitive status as the independent variable and interrater reliability as dependent variable. SETTING: Medicare/Medicaid-certified nursing homes. PARTICIPANTS: 147 residents age 65 or older. MEASUREMENTS: Dual assessments of elderly nursing home residents were performed by nurse assessors using the **Health Care Financing** Administration's new Minimum Data Set for Nursing Home Resident Assessment and Care Screening (MDS). Assessments were classified on the basis of residents' cognitive status, and levels of disagreement between assessors were analyzed. MAIN RESULTS: Overall assessment reliability, agreement concerning a resident's activities of daily living status, and the reliability of estimates of his or her communication skills and sensory abilities were significantly affected by a resident's cognitive status. The presence of cognitive impairment

made these measurements less reliable--especially those related to communication skills, vision, and hearing. CONCLUSIONS: Assessments of residents suffering from cognitive impairment were significantly less reliable than assessments of cognitively intact residents. However, these differences in reliability were not uniform across all assessment domains. When treating the cognitively impaired elderly, clinicians must exercise caution in their reliance on standardized measurements that may be less reliable for this population.

TI Epidemiology of hospitalization for achalasia in the United States.
SO Dig Dis Sci 1993 Feb;38(2):233-44
JT DIGESTIVE DISEASES AND SCIENCES
AD Division of Gastroenterology, VA Medical Center, Milwaukee, Wisconsin 53295.
LA Eng
AB Achalasia is an uncommon esophageal motility disorder of unknown etiology. To gain insights into possible etiologic risk factors, demographic and comorbidity data were obtained from Medicare hospital discharge data files from 1986-1989 on patients aged 65 and older. Age-adjusted sex- and race-specific occurrence rates were calculated for each US state. The rate of comorbid illness occurrence in achalasia patients was compared to that of the entire hospitalized Medicare population. Records of 15,000 achalasia discharges were available for analysis. Achalasia discharge rates increased linearly from age 65 to 94 years. They were similar in males and females as well as whites and nonwhites. High rates were observed in the South and low rates in most states of the East North Central region around the Great Lakes and in the Pacific region. The same geographic pattern was observed in men and women as well as in the two separate subsets of data representing the periods 1986-1987 and 1988-1989. Achalasia was associated with a significantly increased risk for pulmonary complications, malnutrition, and gastroesophageal cancer. The concordant occurrence of achalasia in

patients with Parkinson's disease, depressive disorder, and various other myoneural disorders indicated a possible etiologic relationship. Achalasia appears to represent the clinical end point of several different pathways. Besides aging, different neurologic diseases may contribute to a loss in control of esophageal motility. The geographic pattern could suggest the influence of environmental factors.

 TI Ophthalmology and the Resource-Based Relative Value Fee Scale.
 SO Arch Ophthalmol 1993 Jan;111(1):50-5
 JT ARCHIVES OF OPHTHALMOLOGY
 AD University of Illinois Eye Center, Chicago 60612.
 LA Eng
 AB The Medicare Resource-Based Relative Value Scale for ophthalmology has significantly reduced the level of reimbursement for surgical fees and only minimally increased evaluation and management fees. Some observers have felt that the methods for determining fees were flawed, and, generally, practitioners have been concerned about a potential loss of income. While reimbursement for individual services is being cut, projections through 1996 indicate that ophthalmology, as a specialty, will receive 55% more funding due to historical trends and increasing ranks of providers. This will translate into a more moderate global reduction in revenue of approximately 11%. The possible implications of the Resource-Based Relative Value Scale include a concentration of ophthalmic surgery into fewer practices, which may be able to distribute medical liability costs over a larger number of procedures. To counter the constraints of fee limits, individual physicians will probably seek to enhance their net income by greater use of paraprofessional personnel, the acquisition of new technologies, and the application of improved management skills.

TI The Resource-Based Relative Value Scale. Methods, results, and impacts for ophthalmology.
SO Arch Ophthalmol 1993 Jan;111(1):41-9
JT ARCHIVES OF OPHTHALMOLOGY
AD Urban Institute, Washington, DC.
LA Eng
AB In January 1992, the **Health Care Financing** Administration implemented sweeping legislation that reformed the way Medicare pays for physicians' services. The cornerstone of the reform consists of a new fee schedule based on the Resource-Based Relative Value Scale. This article summarizes the methods and data used to derive the scale for ophthalmology. The results and impacts of the new Medicare payment rates for ophthalmology are also assessed. Using our methods and assumptions, ophthalmologists stand to lose 16% of their Medicare revenues under a fully implemented relative value-based fee schedule. Overall, the fees for performing evaluation and management services will increase, while those for most surgical procedures and diagnostic tests will decrease. Physicians' practice decisions and medical students' specialty choices could be affected. Ophthalmologists who perform work-intensive surgical procedures and spend the majority of their time in the operating room will continue to earn much higher incomes than those who do not.

costs, and service use during the 1980s to assess the effects of recent
federal policy shifts and to project future costs for children. Data
presented in this study are from the **Health Care Financing**
Administration's Medicaid Statistical Report for the years 1979, 1985,
and 1990, three time-points that demarcate major federal policy shifts.
About half of all recipients added to the Medicaid program during the
last decade were children; they comprised 14% of the total cost growth
experienced by the program. In addition, the eligibility distribution
of children receiving Medicaid shifted markedly over the last decade.
In 1979, children receiving cash assistance comprised 90% of total child
recipients; by 1990, this figure dropped to 72%. Future expansions to

the Medicaid program are projected to cost less than the initial expansions. This is because the early expansions disproportionately served infants, who require more hospital services than older children. Despite the major changes in Medicaid eligibility for children during the 1980s, only limited cost shifts occurred in expenditures for children. Children continue to consume a small portion of the Medicaid budget. Congress should explore options for guaranteeing that their share of funding for services will be adequate. Moreover, since future expansions will be far less expensive than those already implemented, accelerating the phase-in process for all poor children may be a more financially feasible policy option than many policymakers anticipate, despite the fiscal hardships facing many states.

TI A federal/state partnership for health system reform.
SO Health Aff (Millwood) 1992 Winter;11(4):7-16
JT HEALTH AFFAIRS
LA Eng
AB In view of the continued lack of consensus regarding health system reform, a new approach is needed to the pluralism that characterizes the U.S. political scene. A two-step strategy can help to break the deadlock around **health care financing** and provision: a framework around which to shape federal/state responsibility for health care and a process to ensure that policy is translated into action. This strategy, called a federal/state compact for health, builds on actions already under way in several states and represents a process that is both incremental and comprehensive in nature. The federal government would take the lead regarding policy making, financing, and establishing benefits. The states would administer the program with flexibility similar to that existing in Canada's provinces.

SO Health Aff (Millwood) 1992 Winter;11(4):162-71
JT HEALTH AFFAIRS
AD Long-Term Care Coverage Branch, **Health Care Financing** Administration, Office of Research and Demonstrations, Baltimore, MD.
LA Eng
AB Budget reconciliation legislation in 1981 created a waiver program whereby states could provide home and community-based care under Medicaid for certain populations. States spent nearly \$1.7 billion on services delivered under these waivers, known as 2176 waivers, in 1991, compared with \$3.8 million in 1982, when only six states were participating in the program. Although these programs have not been rigorously evaluated for effectiveness, they continue to be a popular

approach to delivering care outside of institutions for various groups. Across all states, states spent 13.4 percent of their Medicaid long-term care dollars on care outside of institutions (which includes the 2176 waiver program).

AB The quality of care rendered in ambulatory ophthalmic surgical centers is subject to the standards outlined in the **Health Care Financing** Administration's "Outpatient Surgery Generic Quality Screen Guidelines." Ophthalmic Surgery accounts for 28.2% of all ambulatory surgery performed in the United States. Diabetes, respiratory disorders, renal failure, and hypertension are a few of the clinical problems that are handled in a nontraditional fashion in ophthalmic surgery facilities throughout the United States with excellent results and low incidence of complications. Trends in the clinical management of patients in

ophthalmic surgical centers are described by data obtained in a survey conducted by the anesthesia and surgical staff of the Parris-Castoro Cataract and Laser Center in Bel Air, MD. The survey addressed the current trends in obtaining history and physicals, electrocardiograms, chest radiographs, and laboratory studies before outpatient ophthalmic surgery.

TI Relative performance of for-profit psychiatric hospitals in investor-owned systems and nonprofit psychiatric hospitals.
SO Am J Psychiatry 1993 Jan;150(1):77-82
JT AMERICAN JOURNAL OF PSYCHIATRY
AD Department of Health Administration, Medical College, Virginia Commonwealth University, Richmond 23298-0203.
LA Eng
AB OBJECTIVE: The authors analyzed the differences in operational and financial performance between 42 matched pairs of for-profit psychiatric hospitals belonging to multifacility organizations and nonprofit psychiatric hospitals for the fiscal years ending in 1986 through 1990. METHOD: The pairs of short-term hospitals were matched according to location, standard metropolitan statistical area, or wage index. Analyses were based on data on these hospitals from the **Health Care Financing** Administration. The groups of variables studied included the hospitals' operational performance and productivity, profitability and payer mix, revenue and expenses, and capital structure. Differences in the mean values of the variables for the for-profit hospitals and the nonprofit hospitals were analyzed by pairwise t tests. RESULTS: The for-profit organization hospitals had significantly higher net revenue, lower salary expenses, and higher profits than the nonprofit hospitals. Patients in the for-profit hospitals had longer stays, and these hospitals had fewer full-time employees per adjusted inpatient day and per adjusted discharge. CONCLUSIONS: The higher prices and operating margins of the for-profit hospitals belonging to investor-owned systems reflect the profit-maximizing goal of these facilities. The ability of

for-profit organization hospitals to achieve economies of scale in expenses, however, was not evident except in the case of salary expenses.

JT PHYSICAL THERAPY
AD Department of Physical Therapy, School of Allied Health Sciences, University of Vermont, Burlington 05405-0068.
LA Eng
AB BACKGROUND AND PURPOSE. **Health care financing** for teaching hospitals has undergone significant change in the past decade. This report describes changes in physical therapy practice and clinical education in three New England hospitals from 1984 to 1988. SUBJECTS. Hospital administrators, physical therapy managers, and clinical educators (N = 18) from the three teaching hospitals participated in this descriptive study. METHODS. Demographic, environmental, and participant interview data were gathered and examined to identify changes during this period. RESULTS. Perceived changes in practice include growth in specialized knowledge; increased emphasis on health care quality, efficiency, and accountability; new ethical dilemmas for practitioners; and a changing physical therapy role with new professional development opportunities. Perceived changes associated with clinical education were increased student performance expectations, unchanged resources for clinical education, greater emphasis on student self-directedness, and continued high valuing of this setting for physical therapy clinical education. CONCLUSION AND DISCUSSION. These results indicate significant change in the role of the physical therapist within these settings and suggest how these changes influence the clinical education of physical therapy students in these teaching hospitals.

 TI Contribution of a measure of disease complexity (COMPLEX) to prediction of outcome and charges among hospitalized patients [see comments]
 SO Mayo Clin Proc 1992 Dec;67(12):1140-9
 JT MAYO CLINIC PROCEEDINGS
 AD Section of Biostatistics, Mayo Clinic, Rochester, MN 55905.
 LA Eng
 AB Attention has been focused on the need to adjust hospital reimbursement and outcomes of hospital care for level of illness. Extant measures of disease severity, however, fail to consider the contribution of disease complexity. We developed an easily retrievable measure of disease complexity (COMPLEX) by modifying an existing severity system, computerized Disease Staging. The contribution of COMPLEX (the number of body systems affected with a Disease Staging score of 2 or more) to the prediction of outcome was assessed in two studies: (1) a population-based analysis of readmission and mortality after hospitalization and (2) an analysis of hospital charges among patients who were in an intensive-care unit. The amount of variation in mortality explained by factors included in the **Health Care Financing** Administration model was significantly improved when COMPLEX was added to the model (adjusted odds ratio per body system, 1.83; 95% confidence interval, 1.61 to 2.08). A significant association was also observed between COMPLEX score and hospital readmission after adjustment for age, sex, case-mix, and disease severity (adjusted odds ratio, 1.31; 95% confidence interval, 1.20 to 1.44). When COMPLEX was added to case-mix and disease severity in a model for predicting hospital charges, the

percentage of variation in hospital charges explained by the model increased from 25% to 38%. These findings demonstrate the important contribution of disease complexity to the analysis of outcome of medical care and utilization of resources. Outcome or reimbursement models that do not incorporate disease complexity may negatively affect institutions with a high proportion of patients who have complex conditions.

SO Int J Technol Assess Health Care 1992 Fall;8(4):610-22
JT INTERNATIONAL JOURNAL OF TECHNOLOGY ASSESSMENT IN HEALTH CARE
AD Duke University Medical Center.
LA Eng
AB Positron emission tomography (PET) is a method of nuclear medicine imaging that uses short-lived radiopharmaceuticals to detect and quantify the metabolic abnormalities of disease processes. PET initially was developed in a research environment as a research tool; data from these research studies resulted in the gradual recognition that PET studies would be useful for various routine clinical applications. The diffusion of PET into clinical practice has been slow in comparison with other new imaging methods (e.g., magnetic resonance imaging). This slow diffusion is attributable to several factors, including the complexity and high cost of PET, the uncertain role of the

U.S. Food and Drug Administration in regulating the radiopharmaceuticals that are produced and used on-site for PET studies, and the apparent slow pace at which the **Health Care Financing** Administration and other third-party payers are developing policies for reimbursing for PET.

TI Coding and reimbursement of primary care debridement and excision procedures.
SO J Fam Pract 1992 Dec;35(6):663-72
JT JOURNAL OF FAMILY PRACTICE
AD Department of Family Medicine, East Carolina University School of Medicine, Greenville, NC.
LA Eng
AB Current medical practice requires physicians to accurately report services provided to patients. Patient billing for debridement and excision procedures involves the selection of specific 1992 Physicians' Current Procedural Terminology codes. Although a site-specific surgical procedure code often yields higher reimbursement than a general procedure code, physicians should select the code that most accurately reflects the procedure performed. This review identifies the codes used to report destruction and excision procedures performed by primary care physicians. Included in this review are skin debridement, burn debridement, excision of benign and malignant lesions of the skin and subcutaneous tissue, cyst and ganglion excision, nail excision, anorectal lesion excision, shave, paring, and skin tag excision procedures, and foreign body removal. The **Health Care Financing** Administration's relative value units and one state's published Medicaid payment rates are included for each procedure code. Instructions are provided for selecting between multiple coding options when more than one code describes the service provided.

TI Understanding the Medicare Fee Schedule and its impact on physicians under the final rule.
SO Med Care 1992 Nov;30(11 Suppl):NS80-94
JT MEDICAL CARE
AD Office of Research, **Health Care Financing** Administration, Baltimore, MD 21207.
LA Eng
AB On January 1, 1992, the Medicare program unveiled a new method for paying physicians known as the Medicare Fee Schedule (MFS). The new fee schedule is a complex system of administrative pricing based on the resource inputs used in producing physician services. The MFS consists of three parts: 1) a Relative Value Scale, which assigns to each medical service a value relative to all other services; 2) a conversion factor, which converts the relative values into dollars; and 3) a geographic adjustment factor, which adjusts payments based on geographic differences in the cost of producing physician services. In this article, the following are addressed: how the relative values were determined; how the geographic adjustment factor was constructed; and how the conversion factor was calculated. In addition, balance billing limits and the Medicare Volume Performance Standards (MVPS) are described. Computer simulations of the impact of the MFS on payments to physicians are presented. The authors found that the MFS will 1) redistribute payments away from surgeons, radiologists, and other procedure-based specialties toward the primary care specialties; 2) redistribute payments away from urban areas toward rural areas; and 3) redistribute payments away from invasive procedures and diagnostic tests toward evaluation and management services. The authors conclude with a discussion of the future refinements of the MFS, its applicability to other payers, and whether it will accomplish its intended purposes.

TI Results and impacts of the Resource-Based Relative Value Scale.
SO Med Care 1992 Nov;30(11 Suppl):NS61-79
JT MEDICAL CARE
AD Department of Health Policy and Management, Harvard School of Public Health, Boston, MA.
LA Eng
AB On January 1, 1992, the **Health Care Financing** Administration implemented the 1989 legislation reforming the Medicare payment system for physicians' services. The cornerstone of the new payment reform is the Medicare Fee Schedule (MFS), which is based on the Resource-Based Relative Value Scale (RBRVS). In this article, the major findings of the RBRVS study and its impacts on physician payment are summarized. The authors report the impacts of a RBRVS-based fee schedule on Medicare fees and physicians' income if it were fully implemented, assuming budget neutrality and absence of volume changes in services. Under this scenario, fees for evaluation and management services increase by 15% to 45%, while fees for invasive services and diagnostic tests decrease by 20% to 30%. These changes increase the Medicare income of family practitioners by more than 30% while decreasing the income of most surgical specialties by 10% to 20%.

TI The effect of the new trauma DRGs on reimbursement.
SO J Trauma 1992 Oct;33(4):495-502; discussion 502-3
JT JOURNAL OF TRAUMA
AD EMS/Trauma Program, Hartford Hospital, CT 06115.
LA Eng
AB Reimbursement for trauma care based on prospective payment has not been satisfactory. The **Health Care Financing** Administration introduced four new Multiple Significant Trauma (MST) DRGs in 1991 with the intention of covering patients who have had at least two body sites injured. To determine the effect if any on reimbursement, a sample of patients who were assigned the new DRGs over a 5-month period were analyzed. The analysis compared the calculated reimbursement for these 49 patients based on their total accumulated charges, DRG weights, and the average Medicare dollar blend along with the additional weight factor specific for the study facility. This analysis was compared with an additional analysis determining the reimbursement performed on the same patient sample but with DRG weights determined from DRGs derived from the 1989 DRG GROUPER/FINDER. During the 5-month study period, 5.5% of the patients discharged from the hospital has sustained at least one injury covered by ICD-9-CM codes. Of these, 49 (3.9%) were classified into one of the four new MST DRGs. The majority of patients were male (75.5%), the mean age was 31.8 years, and the total charges accumulated were \$1,809,192.23. The calculated DRG-based reimbursement was \$1,183,495.40, or 65.5% of the total charges. In the second part of the study, using the DRGs available in 1989 for the same sample of patients, the DRG-based reimbursement was \$691,437.72, or only 38.2% of the accumulated charges.(ABSTRACT TRUNCATED AT 250 WORDS)

TI Peer review organization payment denials: comparative analysis of emergency department and non-emergency-department admissions.

SO J Emerg Med 1992 Jul-Aug;10(4):401-5

JT JOURNAL OF EMERGENCY MEDICINE

AD Department of Emergency Medicine, Michigan State University, Kalamazoo.

LA Eng

AB The **Health Care Financing** Administration has contracted with regional peer review organizations to review Medicare admissions and to deny payment for hospital admissions that fail to meet peer review organization criteria. The purpose of this study was to compare emergency department admissions with non-emergency-department admissions with respect to rates of peer review organization denial and the reasons for those denials. All hospital Medicare admissions between January 1984 and April 1987 were retrospectively reviewed. Patients were excluded if they received peer review organization pre-authorization prior to admission. The rest were classified by 1) source of admission (emergency department or non-emergency department), 2) peer review organization decision, 3) reason for peer review organization denial, 4) whether the denial was appealed, 5) the results of appeal. Chi-square or Fisher's Exact Test analysis was performed, and P less than 0.05 was considered to be significant. During the 40-month study period, there were 19,847 emergency department Medicare admissions and 19,752 non-emergency-department Medicare admissions. Of the non-emergency-department admissions, 7887 received pre-authorization. None of the emergency department admissions received pre-authorization. Of the 19,847 emergency department admissions, 433 (2.23%) were denied. Of these denials, 269 (60.7%) were appealed by the hospital; 136 (50.5%) successfully. Of the 11,865 non-emergency department, non-pre-authorized admissions, 333 (2.81%) were denied. Of these denials, 174 (52.2%) were appealed, 76 (43.6%) successfully. Overall, emergency department admissions were significantly less likely to receive peer review organization denial than non-emergency-department, non-pre-authorized admissions (P less than 0.003).(ABSTRACT TRUNCATED AT 250 WORDS)

TI Final CLIA regulations. Clinical Laboratory Improvement Amendments.
SO Health Devices 1992 Nov;21(11):420-5
JT HEALTH DEVICES
LA Eng
AB One clinical pathologist has noted that the broad scope of CLIA means "that every testing situation in the hospital, whether in or out of the laboratory, could now be a liability for ... hospital administration." Portions of CLIA became effective September 1, 1992; thus, it is important that all appropriate personnel are aware of the requirements of CLIA and that all ancillary testing sites are accounted for. CLIA will require unprecedented coordination and cooperation between the clinical laboratory and ancillary sites. Also, clinical laboratories must comply with the sometimes more stringent state regulations and requirements of the Joint Commission on Accreditation of Healthcare Organizations (JCAHO) and CAP. JCAHO, for example, has regulations specific to blood glucose monitors--regulations that demand a high level of QC, proficiency testing, and documentation. In contrast, CLIA categorizes blood glucose monitoring as a waived test. (This classification has been widely criticized by laboratory organizations, which argue that an erroneous result from a blood glucose monitor could be deadly for the patient.

 AB Whereas fractures related to osteoporosis have become a pressing public
 health concern, relatively few epidemiologic studies have focused on
 vertebral fractures. To shed further light on the occurrence of this
 injury, we collected data from the ****Health Care Financing****
 Administration on 151,986 discharges listing a diagnosis of vertebral
 fracture over a 4-year period. After adjusting for age, white women
 experienced the highest rates of discharge, at 17.1 per 10,000 per year,
 followed by white men (9.9 per 10,000), black women (3.7 per 10,000),
 and black men (2.5 per 10,000). Among white women, discharge rates rose
 exponentially from 5.3 discharges per 10,000 population at age 65 to
 nearly 47.8 per 10,000 at age 90. White men, black women, and black men
 experienced less dramatic age-related increases in discharge rates. The
 similarity of these patterns to discharge rates for hip fracture
 suggests that the race-sex differences in vertebral fracture discharge
 rates may be due to differences in the incidence of vertebral fracture.

JT PERSPECTIVES IN PSYCHIATRIC CARE
LA Eng
AB How the treatment planning process is developed and documented in clinical settings is often influenced by various accreditation processes. As healthcare organizations attempt to incorporate written findings and verbal recommendations of surveyors, an incremental approach to the treatment plan often results. The authors describe how they attempted to alleviate this problem by devising a conceptual framework for the treatment planning process using current HCFA and JCAHO standards and data obtained by reviewing treatment plans from almost 100 psychiatric hospitals.

SO Milbank Q 1992;70(3):455-90
JT MILBANK QUARTERLY
AD Department of Health Services Management and Policy, School of Public Health, University of Michigan, Ann Arbor 48109-2029.
LA Eng
AB Nursing-home case mix adjusted payment systems typically base payments on estimates of patients' care needs, but to date the data on their effectiveness are ambiguous. Studies mainly show that access for patients most in need of care appears to improve under these systems. Case mix based payment systems have both positive and negative effects on quality of care and require compensating mechanisms for the potentially harmful incentives they can generate. On the positive side, nursing homes are paid more equitably; the negative aspect is reflected in higher costs, particularly for administration. A **Health Care Financing** Administration (HCFA) demonstration project may provide insights, but its limited number of predominantly small, rural, participating states, its tandem quality assurance system, and potentially confounding market variables may restrict the value of this project. We do not yet have the data to assess the impact of instituting case mix adjustment systems.

TI Coding and reimbursement of primary care biopsy and destruction procedures [see comments]

SO J Fam Pract 1992 Oct;35(4):433-41
 JT JOURNAL OF FAMILY PRACTICE
 AD Department of Family Medicine, East Carolina University School of
 Medicine, Greenville, NC 27858-4354.
 LA Eng
 AB Current medical practice requires physicians to accurately report
 services provided to patients. Billing for destruction of benign and
 malignant lesions and for surgical, needle, and endoscopic biopsy
 procedures involves the selection of specific 1992 Current Procedural
 Terminology (CPT) codes. Payment for these procedures by third-party
 payers often requires the International Classification of Diseases, 9th
 Revision, Clinical Modification (ICD-9-CM) coding for neoplastic
 lesions. This review explains the proper codes to use in identifying
 common biopsy and destruction procedures performed by primary care
 physicians. The **Health Care Financing** Administration's relative
 value units and one state's published Medicaid payment rates are
 included for each procedure code. Instructions for selecting
 site-specific biopsy and destruction codes are provided.

 TI Monthly variation of hospital admission and mortality of peptic ulcer disease: a reappraisal of ulcer periodicity.
 SO Gastroenterology 1992 Oct;103(4):1192-8
 JT GASTROENTEROLOGY
 AD Clement J. Zablocki Veterans Affairs Medical Center, Milwaukee, Wisconsin.
 LA Eng
 AB The occurrence of peptic ulcer is characterized by a seasonal variation, the meaning of which is poorly understood. The present study examined the periodicity of hospital admissions and mortality resulting from gastric and duodenal ulcer to determine its etiologic relevance. Ulcer periodicity was studied in the nationwide data sets of the Department of Veterans Affairs, the **Health Care Financing** Administration, and the Vital Statistics. Both ulcer types were characterized by similar patterns of periodicity. Hospital admissions peaked during the first 3 months of the year, followed by a marked decline during summer and a second smaller peak around October. This pattern occurred independently of age, sex, race, and place of residence. It also pertained to ulcers complicated by hemorrhage or perforation. Although total admissions peaked earlier during the year and showed a less consistent peak in October, there was a close resemblance between the periodicity of all diseases and that of peptic ulcer. Mortality was highest in January and lowest in July for all disease and ulcer diseases alike. The similarity between the periodicity of peptic ulcer and other diseases suggests that the major factors responsible for the cyclic behavior of gastric and duodenal ulcer are not particular to these diseases but affect other unrelated diseases alike.

 TI Changing patterns of hospital use for patients with musculoskeletal disease in Michigan, 1980 to 1987.
 SO Arthritis Care Res 1992 Jun;5(2):111-5
 JT ARTHRITIS CARE AND RESEARCH
 LA Eng

AB Over the past 10 years there have been dramatic changes in **health care financing** in the United States, such as Medicare's Prospective Payment System for hospitalized Medicare beneficiaries, and in health services delivery, such as the growth in health maintenance organizations and other forms of managed care. These changes have occurred largely in response to payors' concerns about the rising cost of health care. A study of such changes in financing and delivery, and how specific groups of patients are affected is necessary so that the effects of these changes on patients' health can be determined. We examined the hospitalization rates for patients with musculoskeletal diseases in Michigan from 1980 through 1987. During this period, the overall age-adjusted hospitalization rates decreased 7.0% per year ($p = 0.001$). The decrease occurred less for surgical discharges (6.0% per year) than for medical discharges (8.6% per year) ($p < 0.001$). While these overall trends are of interest, they obscure disease-specific trends that vary significantly from both the overall, and the medical and surgical trends. For example, while surgical discharges, in general declined, procedures related to major joint and limb reattachment (DRG #209) increased at a rate of 6.3% per year. And while medical discharges in general decreased over this period, discharges for osteomyelitis increased 5.4% per year. The patterns of disease-specific trends offers insight into the possible causes for these changes. Finally, it is important to understand the epidemiology of hospital use to evaluate the effects of new medical care delivery and payment systems on the care of subsets of patients.

JT ASAIO TRANSACTIONS
AD Hepatitis Branch, Centers for Disease Control, Public Health Service, Department of Health and Human Services, Atlanta, Georgia 30333.
LA Eng
AB To determine trends in a variety of dialysis-associated diseases and practices, the Centers for Disease Control surveyed 1,867 chronic hemodialysis centers in the United States in 1989 in conjunction with the annual facility survey performed by the **Health Care Financing** Administration. The response rate to a mailed questionnaire was 92%. These 1,726 centers represented 122,734 patients and 32,486 staff members. The following results were found. 1) During the last 14 years, the incidence of hepatitis B virus (HBV) infection decreased from 3.0 to 0.1% among patients, and from 2.6 to 0.1% among staff members. Over the same time, the prevalence of hepatitis B surface antigen (HBsAg) positivity declined from 7.8 to 1.4% among patients and from 0.9 to 0.3% among staff members. Hepatitis B vaccine was given by 92% of the

centers. By the end of 1989, 19% of susceptible patients and 55% of susceptible staff members had received all three doses of hepatitis B vaccine. From 1982 to 1989, as a result of receiving vaccine, the prevalence of antibody to HBsAg (anti-HBs) increased from 12 to 19% among patients and from 18 to 54% among staff. The incidence of non-A, non-B hepatitis in 1989 was reported to be 0.7% among patients and 0.1% among staff members. 2) Twenty-two percent of the centers reported pyrogenic reactions in the absence of septicemia among their patients, and 51% reported septicemia. 3) The reported incidence of dialysis dementia among hemodialysis patients was 0.2%, with a case fatality rate of 23%. 4) In 1989, 68% of centers reported that they reused disposable dialyzers; these centers treated 73% of the dialysis patient population. Among centers that reused disposable dialyzers, the average number of reuses ranged from 1 to 50 (mean, 12) and the maximum number of times a disposable dialyzer was ever reused ranged from 3 to 150 (mean, 28). Chemical germicides used for reprocessing dialyzers included formaldehyde, Renalin (a peracetic acid-hydrogen peroxide-based germicide), and glutaraldehyde-based germicides. Reuse of disposable dialyzers was not associated with any increased risk of acquiring HBV infection among either patients or staff. However, pyrogenic reactions occurring in clusters were reported more frequently in centers that reused conventional dialyzer membranes compared with centers that did not. This increased risk was associated only with centers that used Renalin or glutaraldehyde for reprocessing (not formaldehyde) and occurred with both automated and manual reprocessing systems.(ABSTRACT TRUNCATED AT 400 WORDS)

 TI Quality assurance issues raised by proposed limited-service rural hospitals.
 SO Qual Assur Util Rev 1991 Summer;6(2):38-46
 JT QUALITY ASSURANCE AND UTILIZATION REVIEW
 AD Division of Health Services Research and Policy, School of Public Health, University of Minnesota, Minneapolis 55455.
 LA Eng
 AB This article explores quality assurance issues that are likely to arise related to limited-service rural hospitals, an institutional alternative to existing rural hospitals. In exploring these issues, we use as an example, the Montana Medical Assistance Facility, a limited-service rural hospital model about to be implemented by the **Health Care Financing** Administration as a demonstration. While such medical assistance facilities will need to meet licensure and certification requirements, it is not reasonable to expect them to meet regulations that are designed for large hospitals. Also, because of their limited resources, medical assistance facilities will likely need outside help from a larger institution to perform quality assurance activities, particularly peer review activities. A key challenge for the medical assistance facility will be to define the nature of this relationship, while retaining ultimate responsibility for quality of patient care. Assuring quality of care is a particularly important issue for medical assistance facilities since community acceptance and financial viability will depend critically on establishing a record for quality of care that

is at least comparable to existing small, rural hospitals.

TI Association between formulary strategies and hospital drug expenditures.
SO Am J Hosp Pharm 1992 Sep;49(9):2207-10
JT AMERICAN JOURNAL OF HOSPITAL PHARMACY
AD California Department of Health Services, Sacramento.
LA Eng
AB National survey data were analyzed to determine whether an association
existed between formulary strategies and hospital drug expenditures.
Data on community hospitals were obtained from (1) ASHP's 1987 national
survey of pharmaceutical services, (2) the American Hospital

Association, and (3) the **Health Care Financing** Administration. Along with size, case mix, and salary information, data were collected on whether the hospitals used a well-controlled formulary, whether they used therapeutic interchange, and how much money they spent on drugs. A logarithmic cost-function model was used to obtain a straight-line equation that expressed the relationships between drug cost per patient day and the other variables assessed. Summary statistics were calculated with data from 514 hospitals. The adjusted coefficient of multiple determination indicated that the model was able to explain 24.6% of the observed variation in drug cost per patient day. A significant association was found between decreased costs and a well-controlled formulary, therapeutic interchange, or both. Hospitals that used either strategy spent 10.7% less for drugs than those that used neither. Hospitals that used both strategies spent 13.4% less than those that used neither. Analysis of national survey data suggests that use of a well-controlled formulary, therapeutic interchange, or both are associated with lower pharmacy drug expenditures.

TI Comparing in-patient classification systems: a problem of non-nested regression models.
SO Stat Med 1992 Jul;11(10):1321-31
JT STATISTICS IN MEDICINE
AD Department of Clinical Epidemiology and Biostatistics, McMaster University, Hamilton, Ontario, Canada.
LA Eng
AB Since 1983, hospitals in the United States have been receiving prospective payment for their in-hospital patient admissions covered under Medicare. Under such schemes each patient is placed in a group by a classification system, known as the Diagnosis Related Groups (DRG), and the hospital is reimbursed by the **Health Care Financing** Administration according to some predetermined group average, adjusted for hospital level characteristics, such as size, location and teaching activity. Recent interest has focused on refining the DRG system or considering totally different systems of classification. Studies designed to compare the ability of different systems to account for between-patient variability in resource consumption in the same dataset lead to the problem of model selection between large non-nested regressions, where resource consumption, measured by length of hospital stay or costs, is regressed on dummy-indicator variables representing

different patient groups. We use a simple measure of fit to develop a symmetric test of the null hypothesis that the two systems account equally well for variability in resource consumption. With this method, unlike methods such as Akaike's AIC criterion, we can quantify the probability of a false positive, and thereby limit the probability of choosing one system over another when it is no better at accounting for variability in resource consumption.

LA Eng
AB Major changes in the federal oversight of nursing home care were passed by Congress and became law as the Nursing Home Reform Amendments of the Omnibus Budget Reconciliation Act of 1987 (OBRA 87). The final regulations to implement OBRA 87 were published in September, 1991. The intent of this article is to provide an overview of selected parts of the nursing home reform regulations, which have a direct impact on physician practice within nursing facilities, and to offer strategies for successful management of the changes that are required. A brief review of the origins of the legislation and the process by which law is turned into practice is provided as a context in which to understand the changes mandated by the Nursing Home Reform Amendments of OBRA 87.

TI Problems in oral **health care financing** for the elderly.
SO Clin Geriatr Med 1992 Aug;8(3):685-92
JT CLINICS IN GERIATRIC MEDICINE
AD School of Dentistry, University of Colorado Health Sciences Center, Denver 80262.
LA Eng
AB The oral health of America's aged has improved dramatically. As the number of elderly swell, their collective need and demand for comprehensive dental services will increase significantly. Payment for those services will pose problems for many, because few options exist for financing dental care among the elderly. Currently most charges are covered by individuals out-of-pocket. Although more older people than ever before have sufficient funds to include dental visits in their health services use, a large proportion of the elderly lack the personal resources necessary to have their numerous dental conditions treated. Innovation is critical. Greater public and private sector support for accessible and affordable dental services must be offered in the future to ensure that the oral health gains of the past decades are not lost because of a lack of financial mechanisms for supporting an adequate level of care.

TI Evaluation of the HCFA model for the analysis of mortality following
hospitalization.
SO Health Serv Res 1992 Aug;27(3):317-35
JT HEALTH SERVICES RESEARCH
AD Department of Preventive Medicine and Biometrics, Uniformed Services
University of the Health Sciences, Bethesda, MD 20814-4799.
LA Eng
AB From 1987 through 1990, the **Health Care Financing** Administration
(HCFA) evaluated variations in the mortality rates experienced by
patients admitted to hospitals participating in the Medicare program.
This study was conducted to evaluate the adequacy of the model used for
that purpose. Detailed clinical data were gathered on 42,773 patients
admitted to 84 statistically selected hospitals. The effect of risk

adjustment using the HCFA model, which is based on claims data, was compared to a risk-adjustment model based on physiologic and clinical data. Models that include claims data were markedly superior to those containing only demographic characteristics in predicting the probability of patient death, and the addition of clinical data resulted in further improvement. The correlation of ranks of hospitals based on a model that uses only the claims data and on one that uses, in addition, clinical data, was .91. As a screen for the identification of "high (mortality) outlier" hospitals, the claims model had moderate sensitivity (81 percent) and specificity (79 percent), a high negative predictive value (90 percent), and a low positive predictive value (64 percent) when compared to the clinical model. The two mortality models gave similar results when used to determine which structural characteristics of hospitals were related to mortality rates: hospitals with a higher proportion of registered nurses or board-certified physician specialists, or with a greater level of access to high-technology equipment had lower risk-adjusted mortality rates. These data suggest that the current claims-based risk-adjustment procedure may satisfactorily be used to characterize variations in mortality rates associated with hospitalization. The procedure could also be used as a basis for further epidemiological analyses of factors that affect the probability of patient death. However, it does not positively identify outlier hospitals as providers of problematic care.

TI Factors affecting interstate use of inpatient care by Medicare beneficiaries.
SO Health Serv Res 1992 Aug;27(3):295-315
JT HEALTH SERVICES RESEARCH
AD Office of Research, **Health Care Financing** Administration, Baltimore, MD 21207.
LA Eng

AB This article examines the extent to which interstate inflow and outflow of patients affects their observed use of Medicare Part A inpatient care. Interstate patient flow can bias utilization rates and may be due to seasonal migration, interstate inpatient care market areas, or purposive seeking of specialized/high-quality care. Examination of state level patient flow data drawn from 1987 Medicare discharge indicate that most interstate patient flow occurs between adjacent states probably as an outgrowth of interstate markets. Regression analyses of patient flow data suggest that while seasonal migration is an important determinant of patient flow, its importance is secondary to that of indicators of the availability of specialized services. These findings suggest research questions that may be best answered in detailed analyses of inpatient utilization in interstate market areas and seasonal migration.

JT ARCHIVES OF PATHOLOGY AND LABORATORY MEDICINE

AD Park Nicollet Medical Center, Minneapolis, Minn. 55416.

LA Eng

AB With the enactment of the Clinical Laboratory Improvement Amendments of 1988 (CLIA 88), the federal government is now using proficiency testing as the primary indicator of laboratory quality. Laboratories with proficiency test failures are now at risk of a variety of harsh

penalties including large monetary fines and suspension of operations. To minimize the risk of failed proficiency testing, we initiated a continuous quality improvement program in our general chemistry laboratory in conjunction with the use of a new survey-validated quality control product. This article describes the quality improvement program and our success in reducing the long-term random error in general chemistry. Despite our improvement program, significant analytical errors (greater than 30% of the CLIA limits) still exist in analytes measured by our chemistry analyzer. These errors are present in nearly the same analytes measured by other common chemistry analyzers indicating the need for improvement in their design and manufacture.

TI **Health Care Financing** Administration's new proficiency testing rules. Use of a statistical approach to predict long-term performance using the categories 'successful,' 'probation,' and 'suspended'.
SO Arch Pathol Lab Med 1992 Jul;116(7):770-6
JT ARCHIVES OF PATHOLOGY AND LABORATORY MEDICINE
AD Department of Pathology and Laboratory Medicine, University of Wisconsin, Madison 53706.
LA Eng
AB Under the Clinical Laboratory Improvement Act of 1967 (CLIA-67) and the Medicare Act, the **Health Care Financing** Administration's proficiency testing rules apply uniformly to all hospital and reference laboratories. We examined the relationship between internal laboratory performance as characterized by bias and coefficient of variation and proficiency testing performance, categorized as "successful," "probation," and "suspended." Under the March 14, 1990, final rule, a laboratory with suspended testing for even one analyte may be required to cease testing in the entire subspecialty, eg, routine chemistry, unless it ceases testing for that analyte. Analyzing this regimen as a Markov process, we obtained the steady-state solution for performance for one to 27 analytes. While 1.1% of laboratories testing for five analytes with internal or day-to-day coefficients of variation at 50% of the CLIA-67 proficiency testing limit would be suspended, 19.5% of laboratories having biases of 50% and coefficients of variation of 33% would be suspended. We conclude that after eight events, there will be an unacceptably high rate of suspensions.

TI Assuring analytical quality through process planning and quality control.

SO Arch Pathol Lab Med 1992 Jul;116(7):765-9
 JT ARCHIVES OF PATHOLOGY AND LABORATORY MEDICINE
 AD Department of Pathology and Laboratory Medicine, University of Wisconsin
 Medical School, Madison.
 LA Eng
 AB United States governmental regulations describe quality assurance as a
 system in which quality control (QC) and proficiency testing are to be
 used to substantiate that routine tests conform to specified performance
 criteria. Careful planning of analytical processes is necessary to
 guarantee that routine tests will achieve the analytical performance
 defined by the **Health Care Financing** Administration proficiency
 testing criteria. These proficiency testing criteria are analytical
 "total error" requirements that need to be translated into operational
 process specifications for the allowable imprecision, allowable
 inaccuracy, and the QC procedure (decision rules, number of control
 measurements) necessary to provide a known or specified level of
 analytical quality assurance. The level of assurance will depend on the
 QC procedure's probability for detecting critical sized errors that
 would cause the quality requirement to be exceeded. Analytical quality
 can be guaranteed by applying statistical QC to verify, with a specified
 probability, that a desired quality requirement is actually achieved in
 routine laboratory testing. Analytical quality assurance, applied in
 this way, can be a quantitative approach for guaranteeing quality
 through process planning and QC.

AB OBJECTIVE--To examine analytic performance by previously untrained and inexperienced subjects using enzyme-linked immunosorbent assay (ELISA) tests developed for decentralized laboratories. Performance variability between tests assigned to the "simple" and "moderately complex" **Health Care Financing** Administration laboratory levels was evaluated. DESIGN--A nonrandomized trial of the Surecell Strep-A chorionic gonadotropin ELISA tests. Each subject processed nine unknown specimens (three negative, three weakly positive, and three strongly positive) for each ELISA test. Subjects were blinded to expected test results. SETTING--An elementary school. SUBJECTS--A convenience sample of 52 students enrolled in the sixth and seventh grades. This age group was chosen because of their ability to generally comprehend instructions and remain attentive to the testing task. INTERVENTIONS--Subjects were either self-trained by reading package insert directions or trained by a manufacturer's sales representative. MAIN OUTCOME MEASURES--Performance was measured as the percentage of correct test results for the unknown specimens. The sensitivity and specificity for each test by operator group were calculated. RESULTS--Subjects demonstrated an overall sensitivity of 97.1% and specificity of 94.7% for human chorionic gonadotropin unknown specimens and a 95.9% sensitivity and 96.8% specificity for group A streptococcus unknown specimens. No significant differences between the self-trained group and the representative-trained group were observed for either group A streptococcus or human chorionic gonadotropin tests. Performance was so high with the first specimen that improvement over time (ie, a "learning curve") could not be demonstrated. CONCLUSION--These ELISA test systems are able to achieve high levels of performance by subjects with no formal laboratory background, no previous method specific experience, and limited self-training.

JT SOCIAL SCIENCE AND MEDICINE

AD **Health Care Financing** Administration, Bureau of Policy Development, Baltimore, MD 21207.

LA Eng

AB Recombinant human erythropoietin (r-HuEPO) is an established and effective therapy for anemia related to end stage renal disease. In addition to its clinical effects, it has been associated with significant improvements in quality of life for anemic hemodialysis patients. The therapy's impact on overall medical care expenditures for these patients remains uncertain, however. In this study, we examine the costs of r-HuEPO as well as potential offsetting reductions in other medical care costs that might result from the therapy. We used data from a randomized clinical trial, a longitudinal study of hemodialysis patients and the clinical literature to estimate the impact of r-HuEPO on transfusion requirements, transfusion-related illness, hospitalization and transplant success for these patients. We estimate that for patients that otherwise would be transfused, the therapy would reduce blood requirements by nearly 10 units per patient annually and hospital use by 8 days per year. In addition, increased transplant success due to r-HuEPO might result in 150 fewer patient months of dialysis treatments each year. Comparing the dollar value of these reductions with the cost of therapy yields a base case net increase in medical care expenditures of \$3425 per patient year. Under varying assumptions, the estimates range from a net cost of \$8320 to a net saving of \$1775 per patient year.

AB The rapidly changing health care environment in the United States will affect the future of nephrology in several areas. Reductions in Medicare spending will affect graduate medical education, physician payments, and, eventually, payments for medical supplies and therapeutic agents. The resource-based relative value system (RBRVS) developed by the **Health Care Financing** Administration (HCFA) will be implemented over the next 4 years, and it is likely that similar plans will be adopted by other insurance carriers. Under this system, payments for the procedure of dialysis will be substantially reduced--decreases in Medicare reimbursement will range from approximately 30% to 60% depending on geographic location and current charges. However, the current economic pressures may have a beneficial effect on the practice of nephrology by providing an incentive to develop standardized practice guidelines that will eliminate wide variations in practices and minimize unfounded litigation. In the near future, attention must also focus on the training of nephrology fellows; ideas for future directions are presented.

 AB Mortality rates for Medicare patients who underwent coronary artery
 bypass surgery were compared with those who had angioplasty or
 angioplasty and bypass surgery. Two data sets were used for this study:
 The first contained information on demographic factors, co-morbidities
 and subsequent mortality on all 96,666 Medicare patients who had bypass
 surgery or angioplasty in 1985; the second contained additional detailed
 clinical data collected using the MedisGroups method on a random sample
 of 2,931 revascularization patients from 6 states. From the national
 data set 30-day and 1-year mortality rates were 3.8 and 8.2% for 25,423
 angioplasty patients and 6.4 and 11.8% for 71,243 bypass surgery
 patients (p less than 0.001 for both time periods). Mortality rates for
 the MedisGroups data were 4.4 and 8.5% for the angioplasty patients and
 6.5 and 11.9% for the bypass surgery patients. After eliminating
 patients admitted with a myocardial infarction, mortality rates were 1.9
 and 6.0% for 632 angioplasty patients and 5.1 and 10.8% for 1,730 bypass
 surgery patients. The risk-adjusted relative risk of mortality for
 bypass surgery versus angioplasty was 1.72 (p = 0.001) for all patients,
 2.15 (p less than 0.001) for low-risk patients and 0.90 (p = not
 significant) for high-risk patients. Results suggest that low-risk
 patients have better survival with angioplasty because of lower
 short-term mortality.

TI Assistants-at-surgery: recognition of the role of the registered nurse.

SO Orthop Nurs 1992 May-Jun;11(3):41-4, 70

JT ORTHOPAEDIC NURSING

LA Eng

AB In the Omnibus Budget Reconciliation Act of 1989 (OBRA '89), Congress directed the Physician Payment Review Commission (PPRC or "the Commission") to make recommendations on payment policies for assistants-at-surgery, including physicians, physician assistants (PAs) and registered nurses (RNs). The National Association of Orthopaedic Nurses (NAON), via the Government Relations Committee and Executive Board, participated in the public hearing on this issue and submitted testimony on the role of the RN first assistant during orthopaedic surgery. In its 1991 report to Congress, the Commission recommended that inappropriate utilization of assistants-at-surgery could be reduced by implementing "profiling"--a variety of techniques to examine the use of assistants. PPRC failed to comment on policies related to non-physician providers, determining that this was a coverage issue, not a payment issue and thus outside the scope of their jurisdiction. However, as global surgical payment policy is further defined by the **Health Care Financing** Administration (HCFA) and Congress, consideration will again be given to incorporating payment for assistants-at-surgery into a comprehensive fee schedule. Recognition of the registered nurse as an assistant-at-surgery will continue to be a primary goal of NAON.

 LA Eng
 AB Under the Clinical Laboratory Improvement Act of 1967 the **Health Care Financing** Administration's proficiency-testing requirement applies to approximately 12,000 hospital, reference, and large-clinic laboratories in the United States. The Wisconsin State Laboratory of Hygiene is approved by the **Health Care Financing** Administration to provide proficiency testing in all specialties and subspecialties. The focus of the program is to provide highly specialized service and support to a limited number of participants in order to assess intralaboratory performance correctly. We report the findings over the four proficiency-testing events in 1991 for the subspecialty of routine chemistry, which serves approximately 470 participants. Failure rates for individual analytes on single proficiency testing events ranged from 0% to 13%. After four events or one year, if the mandated evaluation criteria and failure rules were strictly applied, as many as 11% of the laboratories could have found themselves involuntarily suspended from offering all routine chemistry testing.

AB Proficiency testing (PT), recognized as a quality-assurance (QA) and quality-improvement tool, also has become the cornerstone of the **Health Care Financing** Administration's (HCFA) regulatory strategy under the revised Clinical Laboratory Improvement Act of 1967 (CLIA '67) and the proposed Clinical Laboratory Improvement Amendments of 1988 (CLIA '88). Use of PT as a regulatory tool corrupts it for things it can do better. PT as a primary regulatory strategy has severe limitations. We explore the nature of these limitations and their implications for clinical laboratories as they impact on the long-term success of HCFA's approved regulatory PT programs in 1991 and beyond, and CLIA '88 PT, which is to be implemented in 1994.

AB Many influences outside of physician control have begun to undermine traditional physician autonomy. Studies of physician practices reveal differences not based on patient case mix alone, but on variations in decisions and lack of intra-physician accountability. Failure of physicians to be accountable to each other is related to inadequate due process understanding, fear of legal recriminations from peers, and a traditional long-standing history of individuality and accountability. The malpractice crisis and the advent of a National Practitioner Data Bank of physicians whose privileges or licenses have been modified serves as an impetus to rebuild accountability into a new emphasis on peer review based on optimum patient-focused outcome. To get physician buy-in, a five-step process is described which is separate from professional review of privileges and is seen as collegial, educational, and patient focused.

TI Impact of the Medicare fee schedule on an academic department of medicine.
SO JAMA 1991 Dec 4;266(21):3000-3
JT JAMA
AD Department of Medicine, University of Pennsylvania, Philadelphia.
LA Eng
AB OBJECTIVE--To examine the effect of the Medicare Fee Schedule (MFS) on Medicare revenues in the department of medicine at an urban academic medical center after the MFS is fully implemented. METHODS--Department revenues from Medicare were compared with projected revenues using the MFS proposed by the **Health Care Financing** Administration on June 5, 1991. National Medicare claims data were used to determine differences in service mix between community and academic internists and the impact of the geographic component of the MFS on department revenues. RESULTS--Department revenues from Medicare in 1996 are projected to be 25.5% lower under the MFS than if the current system had continued. Subspecialty sections that perform large numbers of procedures and special tests had the largest decrease in revenues (eg, gastroenterology, -29.8%); however, this did not differ greatly from decreases in sections that mainly provide visits and consultations (eg, general internal medicine, -24.7%). CONCLUSION--The proposed MFS is projected to lead to substantial reductions in department revenues from Medicare. While relative values for services and geographic location will play a role in how individual departments fare under the MFS, the value of the conversion factor used in the final MFS will be the factor of greatest importance.

TI The center effect in heart transplantation.
SO Clin Transpl 1991;:45-59
JT CLINICAL TRANSPLANTS
AD Health and Population Research Center, Battelle-Seattle Research Center, Washington.
LA Eng
AB Transplantation outcomes vary across centers, prompting interest in the notion of a "center effect." The components of this effect are not well understood, although experience is often regarded as the primary factor. Most studies, however, have failed to confirm an association between transplant program activity level and outcome. While there have been several published reports on the kidney transplant center effect, only 1 such (unpublished) report exists concerning heart transplantation. Data for this analysis were obtained from several sources that include: the Registry of the International Society for Heart and Lung Transplantation; the Medicare Provider Analysis and Review data maintained by the **Health Care Financing** Administration (HCFA), various hospital-specific data compiled by the American Hospital Association (AHA); and finally, 91% of all eligible heart programs participated in a special purpose survey intended to obtain critical data on transplant center characteristics. These 4 data sources were combined into a single data base representing 1,602 patients at 114

centers. The data were then analyzed using a discrete piecewise exponential hazards model. This is a nonparametric approach toward the modeling of risk, wherein no assumption is made about the shape of the survival curve. Risk was assessed up to 2 years posttransplant. Overall 1-year patient survival was 82.4%. In the multivariate models, neither recipient nor donor sociodemographic characteristics were associated with patient survival. Clinical characteristics were the most critical predictors of outcome, including use of an artificial device and retransplantation, both of which had a strong adverse effect. This was predictable based upon univariate analyses alone. The results of this analysis suggest that experience is positively related to heart transplant patient survival; however, due to sample size and other considerations, the experience effect did not achieve statistical significance. Nevertheless, while outcomes did vary by center, the extent of variation was not nearly as great as some commentators have argued. This suggests that heart transplantation is a technology that can be acceptably applied in diverse settings with excellent outcomes.

TI Who pays for health care in the United States? Implications for health system reform.
SO Inquiry 1992 Summer;29(2):231-48
JT INQUIRY
AD Health Policy Center, Urban Institute, Washington, DC 20037.
LA Eng
AB This paper examines the distribution of health care spending and financing in the United States. We analyze the distribution of employer and employee contributions to health insurance, private nongroup health insurance purchases, out-of-pocket expenses, Medicaid benefits, uncompensated care, tax benefits due to the exemption of employer-paid health benefits, and taxes paid to finance Medicare, Medicaid, and the health benefit tax exclusion. All spending and financing burdens are distributed across the U.S. population using the Urban Institute's TRIM2 microsimulation model. We then examine the distributional effects of the U.S. health care system across income levels, family types, and regions of the country. The results show that health care spending increases with income. Spending for persons in the highest income deciles is about 60% above that of persons in the lowest decile. Nonetheless, the distribution of **health care financing** is regressive. When direct spending, employer contributions, tax benefits, and tax spending are all considered, the persons in the lowest income deciles devote nearly 20% of cash income to finance health care, compared with about 8% for persons in the highest income decile. We discuss how alternative health system reform approaches are likely to change the distribution of health spending and financing burdens.

AD Division of Injury Control, National Center for Environmental Health and
Injury Control, Atlanta, Georgia.
LA Eng
AB OBJECTIVE: To determine if alcohol use is a risk factor for fall injury
events among community-dwelling older persons. DESIGN: Case-control
study. SETTING: South Miami Beach, Florida. PARTICIPANTS: 320 persons
65 or older who sought treatment at six area hospitals for injuries
resulting from falls; 609 controls, matched for sex and age, selected
randomly from **Health Care Financing** Administration (Medicare) files.
MAIN INDEPENDENT VARIABLES: Self-reported current alcohol use. RESULTS:
No association was found between fall injury events and average weekly
alcohol use. CONCLUSIONS: Further efforts at reducing injuries to older
persons from falls should concentrate on other modifiable risk factors,
including adequate treatment of underlying medical conditions, reducing
inappropriate psychotropic medication use, and installing safety devices
in the home.

TI The role of the Medicare fiscal intermediary and the Regional Home Health Intermediary, Part 1.
SO J Nurs Adm 1992 Jun;22(6):47-53
JT JOURNAL OF NURSING ADMINISTRATION
AD Arent Fox Kintner Plotkin & Kahn, Washington, DC.
LA Eng
AB The Medicare fiscal intermediaries (FIs) are private insurance companies that serve as the federal government's agents in the administration of the Medicare program, including the payment of claims. There are two primary functions for the FI--reimbursement review and medical coverage review. Hospital-based home health agencies relate to the hospital's FI for reimbursement purposes. All home health agencies are assigned to a special FI, the Regional Home Health Intermediary (RHHI), for medical review issues. The same or a different FI may audit the hospital's cost report. Freestanding home health agencies deal with separate reimbursement and medical review divisions within a single RHHI's office. The author reviews the role of the Medicare FI and the RHHI and their relationship to home health agencies. Part 2 will appear in the July/August issue.

TI Risk factors for surgery for prostatic hypertrophy [see comments]
SO Am J Epidemiol 1992 May 1;135(9):974-80
JT AMERICAN JOURNAL OF EPIDEMIOLOGY
AD Department of Community Health, Brown University, Providence, RI 02912.
LA Eng
AB The purpose of this case-control study was to evaluate potential risk factors for prostatic hypertrophy. The cases were 910 residents of Rhode Island who had a partial or total prostatectomy that was not related to cancer in the years 1985-1987. The controls were 2,003 members of the source population who were selected from a list of holders of Rhode Island driver's licenses or a roster of older Americans compiled by the **Health Care Financing** Administration. Cases and controls were interviewed by telephone. The risk of prostatic hypertrophy was elevated in Jewish men compared with Protestants and Catholics and in blacks compared with whites. Risk was reduced in ever-married compared with never-married men, in men who had left school at age 16 years or more compared with those who had left earlier, and in relatively tall or relatively heavy men. Coffee drinking and cigarette smoking were inversely but only weakly related to prostatic hypertrophy. There was a relatively strong, although irregular, inverse relation of beer drinking to prostatic hypertrophy. The associations of spirits and wine consumption with prostatic hypertrophy were weak.

TI Breast cancer in men: risk factors with hormonal implications.
SO Am J Epidemiol 1992 Apr 1;135(7):734-48
JT AMERICAN JOURNAL OF EPIDEMIOLOGY
AD Program in Epidemiology, Fred Hutchinson Cancer Research Center,
Seattle, WA 98104.
LA Eng
AB Cases included in a population-based case-control study of breast cancer
in men were recruited from 10 geographic areas of the United States from
1983 to 1986. Controls, matched to cases on age and geographic area,
were selected by random digit dialing for men under age 65 years and
from **Health Care Financing** Administration files for older men.
Results are based on responses from 227 cases and 300 controls to
questions asked in a standardized personal interview. An increased risk
of breast cancer was most strongly associated with undescended testes
and was also related to orchiectomy, orchitis, testicular injury, late
puberty, and infertility; and a decreasing trend in risk was observed
with an increasing number of children. Relative risk estimates were
also elevated in relation to a history of high blood cholesterol, rapid
weight gain, benign breast conditions, and possibly obesity. These
findings suggest that breast cancer in men develops in response to
androgen deficiency associated with testicular dysfunction and under
conditions associated with excess estrogen. Risk was also found to be
elevated in men with a history of amphetamine use, diabetes, and cigar
smoking and reduced in men with prior head trauma.

TI The impact of **health care financing** on childhood immunization practices.
SO Am J Dis Child 1992 Jun;146(6):728-32
JT AMERICAN JOURNAL OF DISEASES OF CHILDREN
AD School of Business Administration, University of Wisconsin, Milwaukee.
LA Eng
AB OBJECTIVE--To examine the impact of patient insurance status and third-party payment methods on physician immunization practices. DESIGN--Family practice physicians and pediatricians were surveyed to determine whether differences existed in office immunization practices for five childhood vaccines across insurance and payment classes. SETTING--Milwaukee, Wis. PARTICIPANTS--Of 202 Milwaukee area physicians who administer immunizations routinely, 161 (79.7%) returned the questionnaire. RESULTS--Physicians reported immunizing uninsured patients in their offices less often than patients with insurance. When insurance does not pay for immunizations, most physicians (81.6%) said that they left the decision of whether to pay for private immunizations or seek free immunizations from the city health department to the family. Physicians estimated that approximately half of their uninsured patients decline private immunizations. Some physicians (20%) who treat patients receiving Medicaid reported that they immunize patients with Title 19 coverage less often than patients with other types of insurance. No significant differences in frequency of immunization were reported for patients insured by capitated-payment health maintenance organizations, fee-for-service health maintenance organizations, or traditional insurance covering immunizations. CONCLUSIONS--Physicians reported that they do not immunize uninsured and underinsured children as frequently as insured children. Further research is recommended to evaluate the impact of Medicaid enrollment on access to immunization and to develop innovative financing arrangements to ensure that no children leave their physicians' offices without being immunized.

TI Studying outcomes and hospital utilization in the elderly. The advantages of a merged data base for Medicare and Veterans Affairs hospitals.
SO Med Care 1992 May;30(5):377-91
JT MEDICAL CARE
AD Department of Medicine, Dartmouth Medical School, Hanover, NH 03756.
LA Eng
AB That veterans aged 65 years and older are eligible to receive care either in the Veteran Affairs (VA) health care system or in the private sector under Medicare confounds the analysis of veterans' health services utilization and outcomes in two ways. First, changes in

eligibility or financial barriers to access with regard to either system influence veterans' decisions about where to seek needed care. Second, analyses of VA care for elderly veterans that rely solely on VA data sources underestimate both overall utilization and treatment complications. Similarly, failure to consider the contribution of health care delivery in the VA system may confound analyses of health care utilization by the Medicare-eligible population. To study the magnitude of such confounding influences, we linked the Medicare and VA health care administrative databases for residents of New England and New York. Results indicated that, for ten surgical procedures commonly performed in the elderly, as well as for hospitalizations resulting from acute myocardial infarction and hip fracture, VA patients receive from 17.6% to 37.4% of hospital care outside the VA system. Private hospitalizations account for 5.5% to 19.5% of the care received by veterans within 6 months after an initial episode of care in a VA hospital. It was also found that initial hospitalizations for study conditions in the VA accounted for 3.6% of all such hospitalizations among elderly Medicare-eligible men. Although overall hospital utilization appears to be underestimated in VA data sources, it was found that ascertaining mortality from sources available within the VA produced excellent results when compared with deaths recorded in the Medicare enrollment files. A national, merged VA-Medicare data base is feasible and would enhance the validity of analyses of health care delivery both for elderly veterans and for the Medicare population.

TI Predicted and observed effects of the Medicare Optometry Parity Amendment.

SO J Am Optom Assoc 1991 Jul;62(7):525-8

JT JOURNAL OF THE AMERICAN OPTOMETRIC ASSOCIATION

AD SUNY State College of Optometry, State University of New York, NY 10010.

LA Eng

AB The Medicare Parity Amendment of 1987 redefined the conditions of optometric participation and expanded coverage to include all Medicare-covered services which optometrists are authorized to perform under state law. Prior to the law, a number of studies projected costs to Medicare as a result of a change in Medicare policy. This paper reviews these studies in relation to actual Medicare expenditures from 1986 to 1988. The paper describes the impact of the Medicare amendment on payments to optometrists and shows how payments increased from \$12 million in 1986 to \$81 million in 1988. Optometrists substantially increased their market share of Medicare payments from 2.6 percent in 1986 to 11.1 percent in 1988. Indications suggest that a shift of patient visits from ophthalmologists to optometrists has occurred.

TI A comparison of charges by optometrists and ophthalmologists under the Medicare program.

SO J Am Optom Assoc 1991 May;62(5):372-6

JT JOURNAL OF THE AMERICAN OPTOMETRIC ASSOCIATION

AD SUNY, NY 10010.

LA Eng

AB Medicare data obtained from the **Health Care Financing** Administration was analyzed in relation to average allowed charges by optometrists and ophthalmologists. Optometric charges are considerably lower than ophthalmological charges for all services compared. The policy of different reimbursement levels is currently a major issue being considered by the Physician Payment Review Commission. Optometry must demonstrate that the procedure codes for which they submit Medicare claims are comparable and identical in service content to those provided by ophthalmologists.

 TI Proficiency testing from a total quality management perspective.
 SO Clin Chem 1992 May;38(5):615-8
 JT CLINICAL CHEMISTRY
 LA Eng
 AB Public concern over increasing health-care costs plus dramatized testing errors, has resulted in CLIA '88 with its more stringent rules governing laboratory performance. The purpose of the 1990 U.S. **Health Care Financing** Administration Final Rules for Proficiency Tests is to separate the quality laboratory from the poorly performing one. From the perspective of total quality management, the customer (patient) defines quality as virtually error-free test results. The current proficiency testing format defeats this. Its effective purpose is not to identify quality laboratories but to shut down the most prolific laboratories--regardless of their quality. There are two reasons for this. First, the proficiency testing format is incomplete: it is missing a minimum frequency criterion. Second, the data for determining the quality of a laboratory's performance (the degree of error-free results) are not being used. I propose a solution based on continuous improvement that promotes voluntarism, favors the quality laboratory, and reduces federal regulation.

TI Projecting future drug expenditures--1992 [published erratum appears in Am J Hosp Pharm 1992 Apr;49(4):839]
SO Am J Hosp Pharm 1992 Jan;49(1):140-5
JT AMERICAN JOURNAL OF HOSPITAL PHARMACY
AD Practice Management and Managed Care Department, American Society of Hospital Pharmacists, Bethesda, MD.
LA Eng
AB The effects of inflation, generic competition, and the introduction of new drug entities on future drug expenditures are discussed. The impact of inflation can be predicted by analyzing trends in historical data and determining factors that may affect drug use. Useful sources include U.S. Bureau of Labor Statistics Producer Price Index figures for pharmaceuticals, commercially available data on drug product pricing, and market basket indices compiled by the **Health Care Financing** Administration (HCFA) and the American Hospital Association. HCFA predicts that quarterly increases in pharmaceutical prices in 1992-93 will range from 6.4% to 8.1%. Pharmaceutical industry analysts predict overall annual inflation rates for pharmaceuticals in 1991-92 ranging from 8% to 10%. To evaluate generic competition, information on the expiration of patents and market exclusivity can be used. Decreases of 30-70% in the list price of a drug product can be expected after the introduction of a generic product, and the price usually stabilizes at approximately 50% of the list price of the innovator product at the time the first generic product was marketed. Predicting when new drug

entities will be introduced is difficult; analysts say the usual time from filing of a new drug application to FDA approval is two years. The FDA says approval usually follows within a few weeks after an advisory panel's recommendation for approval, and marketing can be expected within a few months after final FDA approval. Assumptions about future drug expenditures should take into account historical and predicted rates of inflation, the status of generic competition for existing products, and the prospects for introduction of new drug entities.(ABSTRACT TRUNCATED AT 250 WORDS)

TI Regional variation in Medicare hospital mortality.

SO Inquiry 1992 Spring;29(1):55-66

JT INQUIRY

AD Center for Health Services and Policy Research, Northwestern University, Evanston, IL 60201.

LA Eng

AB This study examines variation in severity-adjusted Medicare hospital mortality rates across nine U.S. census regions. The extent to which regional variation is reduced by controlling for differences in hospital resources and structure, county-level population characteristics, and the level of federal SuperPRO-identified hospital quality problems is estimated. Hospital resources, population characteristics, and SuperPro process quality scores are significant predictors of hospital mortality rates, but they do not explain the important, highly significant regional differences observed after controlling for hospital case-mix severity.

TI Prescribing home oxygen therapy. What the primary care physician needs to know.
SO Arch Intern Med 1992 Apr;152(4):746-8
JT ARCHIVES OF INTERNAL MEDICINE
AD Department of Internal Medicine, Creighton University School of Medicine, Omaha, NE.
LA Eng
AB Physicians who prescribe home oxygen therapy often find it difficult and time-consuming to complete the required certification of medical necessity because of a lack of in-depth knowledge concerning the Medicare requirements and treatment options. The **Health Care Financing** Administration (HCFA) now mandates that the physician or an employee of the physician complete the form to certify medical necessity (form HCFA-484); otherwise, the home oxygen supplier cannot be reimbursed for equipment and service. Since long-term oxygen therapy is essential to increase survival and to improve the quality of life for patients with hypoxemia due to chronic pulmonary disease, it is

imperative that the primary care physician understand the indications and requirements for therapy and be able to order the most appropriate equipment for the therapeutic needs. This article is intended to provide the physician with the information needed to properly prescribe home oxygen therapy.

TI Rapid detection methods for bacterial identification in urologic office laboratory.
SO Urology 1992 Apr;39(4):334-40
JT UROLOGY
AD Department of Urology, Overlook Hospital, Summit, New Jersey.
LA Eng
AB A regulatory era is taking shape under the **Health Care Financing** Administration (HCFA) which eventually will be implemented under the Clinical Laboratory Improvement Amendments of 1988 (CLIA '88). Sweeping changes are planned for all laboratories, including physician's office

and group practice offices. Both of these groups have previously been exempt from federal controls. Though many urologists have been doing urine cultures and colony counts in their offices for a long time, it is important that precise bacterial identification also be done for good patient care, to control quality and cost, and for more rapid results. Herein, we review many commercial kits now available for precise bacterial identification in the office laboratory. These are largely unknown to most practicing urologists but have been available to microbiologists. They easily can be learned and used in an office or group practice. Urologists are competent to perform these tests, especially with a review course or with assistance from their local hospital microbiology laboratory.

AB Medicare fee schedule amounts are reduced for new physicians during their first through fourth years of practice with limited exceptions. While these reductions applied prior to the new Medicare payment system, they are impacting many new physicians for the first time under the new system. Previously, the **Health Care Financing** Administration (HCFA) did not apply the reductions to physicians in group practices. That exception no longer applies.
