AB OBJECTIVES: To assess the proportion of community-dwelling adults aged 65 years or older who are eligible for referral for lipoprotein analysis and intervention according to the National Cholesterol Education Program (NCEP) guidelines. DESIGN: Cross-sectional study based on examinations and questionnaires collected in 1989 and 1990. SETTING: Four communities in the U.S. in the Cardiovascular Health Study (CHS), a study of risk factors for heart disease and stroke in older adults. PARTICIPANTS: A sample of 4810 men and women ages 65 to 100 randomly selected and recruited from **Health Care Financing** Administration Medicare eligibility lists for the four communities; not institutionalized, not wheelchair-bound, not currently receiving therapy for cancer, not currently taking lipid-lowering medications, and not having eaten in the preceding 9 hours. MEASUREMENTS: Total cholesterol and lipoprotein analysis measured in all participants. RESULTS: Total cholesterol levels were less than 5.17 mmol/L (200 mg/dL) in 37% of participants, 5.17 to 6.19 mmol/L (200 to 239 mg/dL) in 39%, and 6.20 mmol/L (240 mg/dL) or greater in 24%. Compared with their counterparts, older participants, especially those over 80 years of age, were more likely to have levels below 5.17 mmol/L, as were men, nonwhites, and those with coronary heart disease or two or more coronary heart disease risk factors (P less than 0.008 for all values). Based on this screening measurement, 2174 participants were eligible for lipoprotein analysis, 80% were eligible for dietary or drug therapy using NCEP guidelines. Overall, 46% of CHS participants were eligible for lipoprotein analysis and 36% for intervention by NCEP guidelines, based on a single cholesterol measurement. CONCLUSION: A substantial proportion of older adults in this community sample were eligible for lipoprotein analysis and intervention. Prospective studies of elderly

persons are needed to determine the risk for incident coronary heart disease according to NCEP classifications and the benefits of lipid-lowering treatments in persons in this age group so that intervention strategies may best be targeted to an appropriately high-risk group.

TI Redesigned nursing practice: a case management model for critical care.
SO Nurs Clin North Am 1992 Mar;27(1):119-28
JT NURSING CLINICS OF NORTH AMERICA
AD Robert Wood Johnson University Hospital, New Brunswick, NJ.
LA Eng
AB Changes within the health care system necessitate changes in nursing practice. Given the financial environment and the need to balance the cost/quality equation, case management will become increasingly important and has the potential to become the predominant care delivery system of the 1990s. This transition represents a tremendous opportunity for nursing. The CCM role offers many potential advantages and benefits for individual nurses and the profession as a whole. Nurses practicing as case managers have the opportunity to function in a highly professional, independent manner with a great deal of interdisciplinary collaboration. In addition to the challenges and satisfactions of the work itself, the nurse case manager may also enjoy

a higher salary and more scheduling control and flexibility. The broader advantages of case management include its benefits to patients and institutions and its fit with current trends in the health care environment. Nurse case managers manage hospital systems to produce optimal clinical outcomes for patients in the shortest time using as few resources as possible. This approach to care delivery places nurses in a position to demonstrate the tremendous contribution they can make to achieving the institution's goal of delivering high-quality, cost-effective care. Thus, case management fits extremely well with current trends in **health care financing** and outcome measurement. The model described in this article illustrates one approach to implementing these important concepts in a critical care setting.

 TI Use of functional status measures for payment of medical rehabilitation

services [see comments]

SO Arch Phys Med Rehabil 1992 Feb;73(2):111-20

JT ARCHIVES OF PHYSICAL MEDICINE AND REHABILITATION

AD National Rehabilitation Hospital Research Center, Washington, DC 20010.

LA Eng

AB In the search for an appropriate payment system for medical rehabilitation hospitals and units, the use of a functional status measure (FSM) has emerged as a recurring theme. Conceptually, functional status measurement is important because the primary goal of medical rehabilitation is to enhance patient function and independence. Studies indicate that functional status and functional gain are among the best predictors of resource utilization at rehabilitation facilities. This article examines conceptually the use of FSMs in payment for medical rehabilitation in two different types of payment systems--as a means of classifying patients for purposes of determining the applicable payment amount (ie, a "classification system"), and as a means of justifying that payment, or continued payment, for services is appropriate (ie, a "justification system"). Several payment models using an FSM are described and analyzed. An agenda for future research is proposed.

TI Racial and community factors influencing coronary artery bypass graft surgery rates for all 1986 Medicare patients [see comments]

SO JAMA 1992 Mar 18;267(11):1473-7

JT JAMA

AD Division of Biostatistics and Clinical Epidemiology, Medical College of Wisconsin, Milwaukee.

LA Eng

AB OBJECTIVE--This study examines the differences in the rates of coronary artery bypass grafting (CABG) between white and black Medicare patients. DESIGN--This is a cross-sectional study with data from the 1986 **Health

Care Financing** Administration hospital claims records on all Medicare patients, the 1988 update of the Bureau of Health Professions area resource file, and the 1985 Census Bureau's county population estimates file. SETTING--Data are from all Medicare patients in the United States in 1986. MAIN OUTCOME MEASURES--Sex- and age-adjusted CABG rates for whites and blacks over the age of 65 years were computed for each of 50 states and 305 Standard Metropolitan Statistical Areas (SMSAs). RESULTS--Nationally the CABG rate was 27.1 per 10,000 for whites (40.4 for white men and 16.2 for white women), but only 7.6 for blacks (9.3 for black men and 6.4 for black women). Racial differences were greater in the Southeast, particularly in nonmetropolitan areas, than in other regions. Neither white nor black SMSA rates were associated with the rate of admission for acute myocardial infarction (an indication of the amount of coronary artery disease). White rates, but not black rates, were associated with the number of thoracic surgeons per 100,000 people. CONCLUSIONS--For patients insured by Medicare, race is strongly associated with CABG rates, and this association is greater for men than for women and greater in the Southeast than in other parts of the country. Physician supply may relate to the CABG rates for whites.

AB Influenza and its complications remain a major cause of premature death and debilitating illness in the United States, particularly among older persons and those with chronic medical conditions. However, only 30% of persons greater than or equal to 65 years of age responding to the 1989 National Health Interview Survey reported having received influenza vaccine during the previous year (CDC, unpublished data, 1991). In 1988, the **Health Care Financing** Administration (HCFA) and CDC began a congressionally mandated 4-year demonstration project to evaluate the cost-effectiveness of providing influenza vaccine under Medicare. This report reviews preliminary results of the Medicare Influenza Vaccine Demonstration during 1988-1992.

TI Clinical quality initiatives: the search for meaningful--and accurate--measures.

SO Hospitals 1992 Mar 5;66(5):26-32, 34, 36-40

JT HOSPITALS

LA Eng

AB At times, it seems as though every hospital, hospital association, philanthropic foundation and major corporation in the United States is involved in the quality movement in health care. The explosion of quality measurement initiatives that began in the 1980s is continuing apace, with earlier programs being expanded, enhanced, modified and replicated throughout the country in a variety of settings. This cover story looks at the broad efforts to develop clinical quality measurement tools from four different perspectives. First, we provide an update on the Maryland Quality Indicator Project and its ongoing use as a role model for many of the newer clinical indicator projects now being developed. Part two looks at the Joint Commission on Accreditation of Healthcare Organizations and its Agenda for Change project, as well as other large-scale quality measurement programs under way in the private sector that are attempting to determine what indicators are meaningful to use. Part three examines the growing role of corporate payers in pushing hospital-comparison and other assessment programs forward. And in the final section, we look at the federal government's role in developing practice guidelines and outcomes research.

TI Home oxygen therapy under Medicare. A primer.
SO West J Med 1992 Jan;156(1):39-44
JT WESTERN JOURNAL OF MEDICINE
AD Section of Pulmonary and General Medicine, Veterans Affairs Medical Center, Salt Lake City, UT 84148.
LA Eng
AB Medicare recently implemented a new, strict, and complex home oxygen policy and a new oxygen prescription form. Unfortunately, the lack of instructions for the form has led to confusion, frustration, and suboptimal treatment. Long-term oxygen therapy prolongs survival, ameliorates hypoxic organ dysfunction, and improves exercise endurance. Indications for therapy include hypoxemia caused by cardiopulmonary diseases, hypoxemia that occurs with sleep or exercise, and hypoxemic

organ dysfunction. Patients should be stable and have an arterial blood oxygen tension (PaO₂) of 55 mm of mercury (7.3 kPa) or less or arterial blood oxygen saturation (SaO₂) of 88% or less. There should be evidence of hypoxic organ dysfunction when the (PaO₂) is 56 to 59 mm of mercury (7.4 to 7.8 kPa) or the SaO₂ is 89%. A medical review by the insurance carrier is required if oxygen is to be prescribed when hypoxemia is less severe--if the PaO₂ is 60 mm of mercury (8.0 kPa) or more or if the SaO₂ is 90% or more. The instructions for oxygen flow, duration, and equipment must be explicit to ensure adequate therapy. An oxygen concentrator with a small oxygen cylinder portable system fulfills most needs. Oxygen cylinders may be used at low flows for patients who require therapy only during sleep or where electrical power is unreliable. A liquid oxygen system may be prescribed for active patients. Portable equipment should be provided in addition to stationary equipment when patients have resting hypoxemia. Portable equipment alone is sufficient when there is exercise-related hypoxemia with normal oxygenation at rest. Newly developed oxygen-conserving devices may offer longer ambulatory times and possibly lower operating costs.(ABSTRACT TRUNCATED AT 250 WORDS)

TI HCFA mandates new quality screens (more emphasis on histories and physicals and perioperative monitoring).
SO Pa Med 1991 Nov;94(11):42-3
JT PENNSYLVANIA MEDICINE
LA Eng
AB As standards of care are redefined based on new technology or new constructs of what constitutes quality, we can expect changes in the criteria by which our clinical activities are assessed. This is

certainly true for peer review conducted under PRO programs, since the starting point for review is the application of criteria and screens. Review criteria are essentially developed by the PROs and, in Pennsylvania, with assistance of specialty society liaisons. The generic quality screens are HCFA-developed, and their use is mandated. Recently, all PROs received a Directed Change Order (DCO) in which newly revised outpatient generic quality screens were released.

AB From a database of 93,077 in-patient admissions, patients assigned to catastrophic, very severe, moderately severe, and average 30-day mortality risk categories (as defined in Medicare Hospital Mortality Information, 1989 release, from the **Health Care Financing** Administration (HCFA) were selected for study. These admissions account for 30% of all admissions, but 70% of all deaths up to 1 year post admission. To determine whether laboratory information adds to the predictive power of the information used by HCFA, we compare the performance of 1 year survival predictors (Cox model) that use only diagnostic, demographic, and comorbidity information, with the

performance of predictors that also include laboratory information. Using a separate set of patients not used for model definition, we find that laboratory data contain significant prognostic information independent of that already available in non-laboratory data. In HCFA's catastrophic disorders for example, non-laboratory information reduces the average risk of predicting a wrong outcome by 17% relative to considering only catastrophic group membership, and adding laboratory data reduces this risk by a further 21%. These improvements result primarily from considering the outcomes of a small set of routine laboratory tests (maximum BUN, AST, and WBC, and minimum CO2, hematocrit, and sodium).

TI Physician payment reform: issues for Canadian radiologists.

SO Can Assoc Radiol J 1991 Dec;42(6):406-11

JT CANADIAN ASSOCIATION OF RADIOLOGISTS JOURNAL

AD Faculty of Medicine, University of Manitoba, Winnipeg.

LA Eng

AB Policy decisions taken by the US Congress in the 1980s to restrain health care costs included the designation of diagnostic-related groups, the creation of scales of relative value and legislation to introduce free-for-service payment to physicians in 1992; discrepancies in the system are to be corrected by 1996. Under federal contract a system of resource-based relative-value scales was created for all medical disciplines except radiology, which by special legislation prepared its own experience-based relative-value scale. The scales are based on magnitude estimation of the work of physicians and analyses of actual costs. Codes for medical services have been published, which include a weighting for each service in relation to all others. Multiplication by a conversion factor establishes the fee to be paid by the carriers acting for the **Health Care Financing** Administration. The relative values will be updated every 5 years. Publication of this information for US Medicare patients (the disabled, the elderly and those with end-stage renal disease) will likely have a profound effect on the physician payment system in Canada. Under the reformed system the lifetime earnings of all physicians will become more similar. Four problem areas are discussed in the paper: self-referral, administrative complexity, malpractice and the plight of those without medical coverage. Resolution of these problems is being actively sought.

 AB BACKGROUND--There is a general perception that procedural medical
 services are reimbursed at an inappropriately greater rate than
 cognitive services. By congressional mandate, the **Health Care
 Financing** Administration (HCFA) has been directed to establish a
 Medicare fee schedule to shift funding under a budget-neutral assumption
 from procedural to cognitive services. To provide a rational basis for
 this change, Hsiao et al (Harvard-Hsiao) developed a resource-based
 relative value scale (RBRVS) that equates the value of a service to the
 resources necessary to generate the service. METHODS--Instead of
 focusing on relative values and fee schedules
 ("price-per-unit-service"), the present study employs the standard
 commercial/industrial method of determining reimbursement rate (income
 divided by hours of labor) for 15 medical and surgical specialties.
 Data from independent sources are used to determine income and hours of
 professional effort for each of the specialties studied. Harvard-Hsiao
 and HCFA predicted the percent change in income for each of the
 specialties under the initial RBRVS and the HCFA fee schedule. The
 predicted income was then employed in this study to recompute
 reimbursement rates under the newly proposed payment systems. RESULTS:
 CURRENT PAYMENT SYSTEM--Average annual incomes for medical and surgical
 specialties are \$124,500 and \$176,600, respectively, a 42% difference (P
 = .03). Average weekly work hours (nominal hours, as adjusted for
 overtime) for medical and surgical specialties are 70.6 and 87.8,
 respectively (P = .005). Average hourly reimbursement rates for medical

(\$33.90) and surgical (\$38.80) specialties are not substantially different (P, not significant). The difference in annual income is explained by the 17.2 hours per week of additional work hours by surgeons. The erroneous perception that procedurists are reimbursed at a higher rate than cognitive practitioners likely arises from differences in billing methods by which surgeons shift charges for cognitive work hours to the 18% of their time spent in the operating room. RESULTS: PROPOSED RBRVS AND HCFA PAYMENT SYSTEM--The income of all specialties is equalized about a mean of \$132,500 (+/- \$21,400 [1 SD]) by varying reimbursement rates in such a way that the effect of working hours is fully discounted. Reimbursement rates under the proposed payment system make no recognition of the hours of professional effort, postgraduate specialty training, or putative differences in the nature of the physician's work. CONCLUSION.--The RBRVS, and the HCFA fee schedule to the extent that it is based on that scale, are inappropriate bases for the reform of the physician reimbursement system.

AB Demographic trends and increasing demand, as well as the intricacy of the emerging field of menopause medicine, dictates the need for a multidisciplinary approach for the care of the peri- and postmenopausal patient. A menopausal program benefits the individual patient by obviating the acute symptoms and by preventing long-term consequences. As morbidity and mortality rates associated with the long-term implications are reduced, substantial public health aspects are also beneficially affected. Cost effectiveness of a menopause program and routine HRT should be calculated as the net present value (NPV) for the **health care financing** program, and should prove to be greater than the NPV of future costs anticipated without an investment in primary preventive menopause program. We believe that the educated use of a menopause counseling program will yield an increasing benefit for the individual patient and the community. Should menopause be regarded as an endocrinopathy, thus justifying routine HRT, or are we engaged in the "medicalization" of a physiologic process? Bearing in mind the data reviewed above, it seems to us that ample reason exists to make every woman aware of the opportunity to receive long-term HRT. The decision to use it depends heavily on the patient's own informed assessment of her particular benefit-risk equation. Combined-continuous estrogen-gestagen replacement seems to provide the desired multisystem beneficial effects, and at the same time be the most convenient and associated with the least short-term side effects. Although emerging trends regarding the long-term risks associated with the use of such regimes are reassuring, more information needs to be elaborated before final conclusions can be offered.

TI A pilot study of state surveying methods for ESRD facilities [see comments]
SO Nephrol News Issues 1991 Jun;5(6):43-4, 49-52
JT NEPHROLOGY NEWS AND ISSUES
LA Eng
AB End Stage Renal Disease (ESRD) facilities must meet certification requirements to receive Medicare reimbursement from the **Health Care Financing** Administration, Department of Health and Human Services (DHHS). State survey agencies, operating under contract with DHHS, assess compliance with conditions and standards for all Medicare facilities. The survey process has been criticized by renal professionals and organizations for its lack of objective criteria, because thresholds have not been established, and for the lack of a severity index. The current process promotes subjective decision making in determining facility deficiencies. Efforts to reorganize the survey process to make it more outcome-oriented are being initiated and, while this is laudable, there is no assurance that the process will be effective. Network #5 conducted a pilot study of state survey results to profile data for Medical Review Board (MRB) analysis and to identify potential areas where educational activities could be focused. Network #5 consists of dialysis and transplant providers in the District of Columbia (D.C.), Maryland, Virginia, and West Virginia. There are 139 dialysis facilities and 13 transplant centers serving over 7,000 dialysis patients. This pilot study was a retrospective analysis of surveys conducted in dialysis units that were operational as of August, 1988. This study did not include transplant providers.

 TI Understanding the regulatory requirements for dialysate.
 SO Nephrol News Issues 1991 Jan;5(1):13, 15
 JT NEPHROLOGY NEWS AND ISSUES
 LA Eng
 AB It is important for providers to remember that dialysate is considered by federal regulatory agencies to be a medical device, but that most of the regulations are aimed at the manufacturers. The manufacturers are subject to FDA inspection and they must comply with Good Manufacturing Practices. Once the product reaches the provider's door, the manufacturer's responsibility ends, as does most close regulation. The best way for facilities to protect themselves is to develop a good quality assurance program that establishes and maintains policies and procedures which will ensure safe and effective use of dialysate.

 SO J Am Geriatr Soc 1991 Dec;39(12):1217-20
 JT JOURNAL OF THE AMERICAN GERIATRICS SOCIETY
 AD Department of Psychology, Craig Hospital, Englewood, Colorado.
 LA Eng
 AB Of all the reasons that justify a decision to withhold or withdraw a feeding tube, the most basic is that it is not needed in order to nourish the patient adequately and safely. The controversy that surrounds feeding tubes decisions in the so-called right-to-die context has distracted attention from this aspect of their use. This creates the risk that they will be initiated inappropriately, without adequate evaluation or consent. By re-incorporating the concepts of medical indication and the least restrictive alternative doctrine into the consent process, as new federal regulations require, physicians can restore balance to clinical judgment and deter improper practices. In order for these concepts to make a real difference to patients and physicians, society must improve the quality of care it provides the elderly.

 AB *Health* *care* in the United States is in crisis. The desire to provide
 care continually conflicts with the need to contain costs.
 Historically, physicians have opposed the demand for *health* *care*
 reform, and although many physicians have responded to the current
 crisis with ambivalence, apathy, or frustration, they have the
 knowledge, capability, and opportunity to advocate for and to effect
 reform within the *health* *care* delivery system. Many believe that the
 acknowledgment of costs as a factor in treatment decisions

compromises their role as patient advocates, but in the face of increasing government controls and the corporatism of medicine, the human link between physician and patient is even more valuable. The current crisis in *health* *care* necessitates cost control. If physicians conscientiously undertake their political, professional, and personal roles, they can *reform* the *health* *care* delivery system in the United States while compassionately advocating for their patients. Author-abstract.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB The author discusses the need to make corrections in the U.S. *health*
care system, describes the simplistic and money-oriented definition
that many persons have of *"health* *care* *reform,"* and discusses the
issues he thinks will and will not be dealt with in the coming
reforms of the *health* *care* system. He maintains that true *reform*
would deal with matters such as restraining expansion of the *health*
care industry, setting reasonable fees, and confronting the harmful
social and environmental conditions that result in high "medical"
care costs and poor *health* statistics. The medical
profession--including academic medical centers--has a large role to
play in true *health* *care* *reform,* which will involve facing the major
barriers (which he outlines) that are now impeding important *reforms*
(e.g., increasing the number of generalist physicians; finding better
ways to pay for medical students' and residents' education). The
profession cannot make progress in true *reform* without developing a
vision of what the U.S. *health* *care* system should be and becoming
active in moving toward that vision, acting in the interests of both
the individual patient and the community as a whole. The author
outlines some of the barriers to finding that vision (such as the
influence of third-party payers on the doctor-patient relationship
and the fragmentation of medicine and medical education by
specialties and subspecialties) and proposes the characteristics and
values of the kind of medical education and community involvement of
academic medical centers that can help create the needed vision,
regain the trust of the public, and thereby *reform* *health* *care* in the
interests of both the community and the profession.

LG English (EN).
AB What has the Association of American Medical Colleges (AAMC) accomplished in the last 25 years in its efforts to advance medical education, biomedical research, and *health* delivery in this country? Can the AAMC's past accomplishments help predict how it will respond to future challenges? To answer these questions, the author traces in detail the recent history of the AAMC, focusing on the expansion of the association's role and constituencies and how these and other changes were precipitated by recommendations in the AAMC's 1965 "Coggeshall Report." He also recounts how the AAMC has responded to the pressures and needs of recent years (such as fostering an increase in the number of practicing physicians) and describes in detail the organization and functions of the AAMC's staff, with emphasis on its six divisions and the fact that many of the complex issues that confront the AAMC transcend the boundaries of governance councils and staff divisions and dictate that association policy be based on broad consensus. Looking ahead, he sees at least four important activities that the AAMC will continue to be involved with: fostering the education of more minority students; promoting *health* services research; finding an appropriate role in the evolution of *health* *care* *reform*; and addressing the need for academic medicine to be more socially responsive. The author concludes that the AAMC's highly regarded record, its organization, and its financial stability all indicate that it will do well as it tackles the issues on the horizon and others not yet in view.(ABSTRACT TRUNCATED AT 250 WORDS).

 LG English (EN).
 AB Stevens' question "Who Gets *Care?*" is in the tradition of those
 arguing for increased access and a more equitable distribution of
 society's benefits. As such, it provides a framework for nursing
 scholarship concerned with social as contrasted with individual
 interventions. Nursing's Agenda for *Health* *Care* *Reform* advances the
 argument still further by questioning the ideology reinforced by the
 current system, and offering an alternative system, alternative
 services and agents. In so doing, the proposed agenda questions the
 dominant ideology and is, therefore, more accurately a radical
 departure from the status quo than a *reform.* While there are some
 implicit assumptions of both *reform* and radical change embedded
 within the work of those addressing a "curriculum revolution," the
 discussion would benefit from explicit expositions of both the social
 construction and social function of higher education.

SO JAMA. 1993 Feb 17. 269(7). P 889-94.
JT JAMA.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB OBJECTIVE--To examine the determinants of *health* insurance coverage for Latinos in the United States and how different targeted strategies for *health* *care* *reform* differentially affect the country's major ethnic groups, focusing on the implications for the Latino population. DESIGN--Data from the 1980 and 1990 Current Population Surveys were used to compare the insurance status of nonelderly (< 65 years) Latinos with the Anglo (non-Hispanic white), black, and Asian and other populations by estimating the attributable fraction for selected covariates. The effects of *health* *care* *reform* strategies on the coverage of the major ethnic groups were simulated from these data. MAIN OUTCOME MEASURES--Percentage uninsured, percentage insured by Medicaid, and attributable fraction for covariates. RESULTS--Latinos have the worst *health* insurance coverage of any ethnic group in the country. Approximately 39% of Latinos are uninsured compared with 13.8% for the Anglo and 24% for the black population. Providing coverage to all the poor could reduce the uninsured rate for Anglos by about 23%, whereas the reduction among Latinos could be about 37% and among blacks about 42%. Similar reductions could be achieved by covering all workers and their minor dependents. Regardless of the approach to *reform,* however, Latinos would remain with high absolute rates of uninsured. CONCLUSIONS--Differences in Medicaid eligibility, labor force characteristics, and family composition between Latinos and other ethnic groups suggest that policy initiatives may affect Latinos differently. Targeted strategies, such as employer mandates, "pay-or-play" programs, or Medicaid expansions, can improve coverage, but many Latinos could still remain uninsured. Author-abstract.

 LG English (EN).
 AB In the second part of a two-part paper, the three major proposals for U.S. *health* *care* *reform--the* government-sponsored model, the employment-based model, and the market *reform* model--are reviewed. Barriers to their success include the current economic crisis, the lack of a clear consensus, and the high costs of the proposals. Most proposals limit the extent of psychiatric coverage; some exclude such coverage from minimum benefit packages, an area of concern for clinicians. The author concludes that any substantial *health* *care* *reform* is unlikely in the near future. A thoughtful, realistic, and yet vigorous strategic plan is needed now to forestall the possible exclusion of significant mental *health* coverage. The basic elements of such a plan are reviewed.  LG English (EN).
 AB The U.S. *health* *care* system is in the midst of a severe crisis. More than 50 million Americans are uninsured or underinsured. Medicare and Medicaid are not adequately serving populations in need. Analyses and *reform* proposals are often based on biased interpretations of data, resulting in confusion and heated debate. To avoid jeopardizing psychiatric *care* in a national *health* *care* *reform* movement, we must understand the causes of the national crisis. In the first part of a two-part paper, the author describes factors such as demographic trends and limitations in public *health* coverage that have contributed to the crisis. Outcomes of the current system include higher morbidity and mortality among the

uninsured and a high prevalence of untreated illness. The author reviews direct and indirect costs of *health* *care* and concludes that in attempts to solve the difficult equation of access, cost, and quality, mental *health* services are in serious jeopardy.

AB *Health* *care* *reforms* introduced in Italy in the late 1970s triggered
a profound rethinking of the role of general practitioners (GPs) in
prevention. We interviewed 209 GPs registered in the Torino area to
delineate their beliefs, attitudes, and practice patterns in relation
to prevention. We examined an array of primary and secondary
preventive interventions, including influenza vaccination of the
elderly; counseling activities related to smoking, alcohol
consumption, accidents, contraception, safety helmets, and seat
belts; and early detection of hypertension and lung, cervical, and
breast cancers. Improvement can still be made in the full
implementation of preventive practices. We examine features of the
organization of medical practices in Italy that impede the
integration of preventive interventions in primary *care.*

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB BACKGROUND. The theory of managed competition holds that the quality and economy of *health* *care* delivery will improve if independent provider groups compete for consumers. In sparsely populated areas where relatively few providers are required, however, it is not feasible to divide the provider community into competing groups. We examined the demographic features of *health* markets in the United States to see what proportion of the population lives in areas that might successfully support managed competition. METHODS. The ratios of physicians to enrollees in large staff-model *health* maintenance organizations were determined as an indicator of the staffing needs of an efficient *health* plan. These ratios were used to estimate the populations necessary to support *health* organizations with various ranges of specialty services. Metropolitan areas with populations large enough to support managed competition were identified. RESULTS. We estimated that a *health* *care* services market with a population of 1.2 million could support three fully independent plans. A population of 360,000 could support three plans that independently provided most acute *care* hospital services, but the plans would need to share hospital facilities and contract for tertiary services. A population of 180,000 could support three plans that provided primary *care* and many basic specialty services but that shared inpatient cardiology and urology services. *Health* markets with populations greater than 180,000 would include 71 percent of the U.S. population; those with populations greater than 360,000, 63 percent; and those with populations greater than 1.2 million, 42 percent. CONCLUSIONS. *Reform* of the U.S. *health* *care* system through expansion of managed competition is feasible in medium-sized or large metropolitan areas. Smaller metropolitan areas and rural areas would require alternative forms of organization and regulation of *health* *care* providers in order to improve quality and economy. Author-abstract.

 JT PUBLIC *HEALTH* REPORTS.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB Before World War II, Czechoslovakia was among the most developed European countries with an excellent *health* *care* system. After the Communist coup d'etat in 1948, the country was forced to adapt its existing *health* *care* system to the Soviet model. It was planned and managed by the government, financed by general tax money, operated in a highly centralized, bureaucratic fashion, and provided service at no direct charge at the time of service. In recent years, the *health* *care* system had been deteriorating as the *health* of the people had also been declining. Life expectancy, infant mortality rates, and diseases of the circulatory system are higher than in Western European countries. In 1989, political changes occurred in Czechoslovakia that made *health* *care* *reform* possible. Now *health* services are being decentralized, and the ownership of hospitals is expected to be transferred to communities, municipalities, churches, charitable groups, or private entities. Almost all *health* leaders, including hospital directors and hospital department heads, have been replaced. Physicians will be paid according to the type and amount of work performed. Perhaps the most important *reform* is the establishment of an independent General *Health* *Care* Insurance Office financed directly by compulsory contributions from workers, employers, and government that will be able to negotiate with hospitals and physicians to determine payment for services.

 JT ARCHIVES OF INTERNAL MEDICINE.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB Calls for major *reform* of the *health* *care* delivery system have been sounded at both the state and federal level. However, given the lack of consensus on *health* *care* *reform* at a federal level, more than half of the states are developing initiatives for universal access to *care.* In 1989, the Minnesota legislature created the *Health* *Care* Access Commission to develop a blueprint for universal access in Minnesota. To assist this effort, we studied the extent and nature of uninsurance and underinsurance within the state. In this article we report the findings of that study and discuss how the findings were first used to develop recommendations for universal access legislation. We then describe the fate of the legislation. Finally, we describe the veto and the creation of HealthRight, the recently enacted plan for *health* *care* *reform* bill in Minnesota. This plan simultaneously expands access to *care* and aims to contain *health* *care* costs. Author-abstract.

 PT CURRENT-BIOG-OBIT (CBO). HISTORICAL-ARTICLE (HRT). JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB Current issues in pharmacy are discussed and recommendations are made to help pharmacy demonstrate its value in *health* *care.* There is a need for pharmacy to actively demonstrate and communicate its value in *health* *care.* Educational requirements should reflect the values

of the profession. In the debate over the entry-level Pharm.D. degree, the profession must not lose sight of the principal goal of elevating the basic competencies of all pharmacists. Graduate-level education will continue to be valuable, but the degrees and programs should be modified to meet current and future needs. Residency training will become increasingly essential. A well-defined corps of pharmacy technicians is needed. The profession should strive to meet the needs of society rather than confining itself to traditional practice definitions. This will involve increased interaction with patients. Also, pharmacy directors must become more creative in allocating existing resources and building arguments for expansion. When patients recognize the value of pharmacy services, they will seek out and demand those services. Pharmacists must get involved in deliberations regarding *health-care* *reform.* They have a responsibility to promote preventive medicine and healthy life-styles. They should actively promote the rational use of all medications. Although tremendous progress has been made in advancing the concept of pharmaceutical *care,* the profession still has work to do in communicating its value to the public. Author-abstract.

 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB Signs of discontent with the *health* *care* system are growing. Calls
 for *health* *care* *reform* are largely motivated by the continued
 increase in *health* *care* costs and the large number of people without
 adequate *health* insurance. For the past 20 years, *health* *care*
 spending has risen at rates higher than the gross national product.
 As many as 35 million people are without *health* insurance. As
 proposals for *health* *care* *reform* are developed, it is useful to
 understand the roots of the cost problem. Causes of spiraling *health*
 care costs include "market failure" in the *health* *care* market,
 expansion in technology, excessive administrative costs, unnecessary
 care and defensive medicine, increased patient complexity, excess
 capacity within the *health* *care* system, and low productivity.
 Attempts to control costs, by the federal government for the Medicare
 program and then by the private sector, have to date been mostly
 unsuccessful. New proposals for *health* *care* *reform* are
 proliferating, and important changes in the *health* *care* system are
 likely. Author-abstract.

 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB Minnesota's *health* *care* *reform* plan (by any name) is a cost-containment bill with provisions to provide *health* insurance for some uninsured people, to examine quality of *care,* to increase support for rural provider education and migration to rural practice, and to develop state and regional *health* planning procedures. It is an ambitious bill with very tight time frames, vague language, and heavy reliance on regional commissions and volunteer groups that are just now being established. Will it have an impact on rural *health* *care?*

Undoubtedly, it will. But somewhere between what the bill says and the desired outcome is a void that physicians can help fill with constructive work and criticism. If physicians do not take the lead, someone else will fill that void--nonphysician providers, legislators, bureaucrats, or consumers. Or the structure could implode, taking all of us with it. Author-abstract.

JT INQUIRY.
PT CONGRESS (CON).
LG English (EN).
AB In January 1992, the Physician Payment Review Commission held a
conference to learn about the appropriateness of present uses of
profiling of practice patterns, and to identify what will be required
to realize the full potential of this technique in the future. The
conference addressed the data needs of profiling, the development of
valid and relevant profiles, the impact of profiles on medical

practice, and controversies surrounding public access to profiling information and the uses to which profiling has been put. This paper, based in part on that conference, reviews the basic concepts that underlie profiling and describes the roles that profiling can play in quality improvement, assessment of provider performance, and utilization review. It uses case studies to illustrate the types of problems that have arisen in actual usage and discusses what will be required to resolve them. The final section describes the roles that profiling can play in achieving the goals of *health* *care* *reform,* and concludes with what is needed in data and infrastructure development to improve the quality and usefulness of profiling.

 TI Actuarial status of the Social Security and Medicare programs.
 SO Soc-Secur-Bull. 1992 Summer. 55(2). P 36-42.
 JT SOCIAL SECURITY BULLETIN.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB The Boards of Trustees for the two Social Security and the two
 Medicare Trust Funds recently released their annual reports to
 Congress detailing the operations of the trust funds during 1991 and
 their projected financial status for future years. Based on the
 Trustees' best estimates, the reports show: The Federal Old-Age and
 Survivors Insurance (OASI) Trust Fund will be able to pay benefits
 for about 50 years. Congress will eventually need to take action to
 assure the long-range financing of the program. The Federal
 Disability Insurance (DI) Trust Fund will be able to pay benefits for
 only about 5 years and is not adequately financed. As a result, the
 Board is required to make a separate report to the Congress on the
 unfavorable financial condition of this trust fund. The Board urges
 that prompt legislative action be taken to improve the financial
 integrity of the trust fund, after a review of the disability
 program. The Federal Hospital Insurance (HI) Trust Fund will be able
 to pay benefits for only about 10 years and is severely out of
 financial balance in the long-range. The Trustees urge the Congress
 to take additional actions designed to control HI program costs
 either through specific program legislation or as a part of enacting
 comprehensive *health* *care* *reform.* The Federal Supplementary Medical
 Insurance (SMI) Trust Fund is financed on a year-by-year basis and,
 on this limited basis, is adequately financed. The Trustees urge the
 Congress to take additional actions designed to control SMI costs

either through specific program legislation or as part of enacting more comprehensive *health* *care* *reform.* Author-abstract.

 JT NURSING AND *HEALTH* *CARE*.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB Nursing's Agenda for *Health* *Care* *Reform* (1991) embraces primary
 health *care* as the focus of a restructured *health* *care* system. As
 part of this reformed system, consumers would access the most
 cost-effective providers in community-based settings. Removal of
 financial and regulatory barriers that limit consumer access to
 providers, such as lack of direct reimbursement by Medicare for nurse
 practitioners, should be eliminated according to this plan. Senate
 bills S2103 and S2104 have been recently introduced to the U.S.
 Senate mandating reimbursement for services provided by nurse
 practitioners, clinical nurse specialists, nurse midwives, and
 physician assistants at 97% of physician payment. The aim of this
 global legislation is to eliminate the current piecemeal mechanisms
 for nurse practitioner reimbursement and remove financial
 disincentives. Case examples presented in this article illustrate
 how obstacles to reimbursement limit access to *care* for consumers.
 Quality of *care,* opportunities for autonomous practice, and control
 of nursing practice issues have been highlighted as well by the case
 format. It is intended that these cases would be useful to support
 changes in patterns of nurse practitioner reimbursement.

JT AMERICAN JOURNAL OF LAW AND MEDICINE.
PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).
LG English (EN).
AB In 1989 and 1991, the Oregon legislature enacted a series of initiatives to extend *health* coverage to uninsured state residents. Among these initiatives is an act that seeks to extend a modified set of Medicaid benefits to state residents with family incomes below the federal poverty level. This act also reduces benefits the state is now required to provide to Medicaid-enrolled women of childbearing age and children. This Article explores the legal context in which the Oregon Medicaid experiment must be evaluated. It argues that by reducing the level of coverage to which tens of thousands of exceedingly poor, Medicaid-eligible women and children are entitled,

the experiment falls outside the scope of valid research that the United States Department of *Health* and Human Services may either sanction or fund. The Article also discusses the implications of the Oregon experiment, if approved, for the future direction of the Medicaid program in particular, and for *health* *care* *reform* for the poor, generally. Author-abstract. 131 Refs.

AB The *health* insurance industry has experienced a pronounced six-year cycle of earnings for nearly three decades--three years of profits followed by three years of losses. This profitability cycle triggers a turbulent pricing cycle. After reviewing three schools of thought about the causes of the cycle, in this article we examine new evidence to determine the probable impact on the cycle of a private-public, universal coverage, national *health* plan. We find no evidence of a cycle in the pricing and use of *health* *care* services. Since 1985, the relationship between the overall economy and *health* insurance trends has weakened. We conclude that the root causes of the cycle are essentially internal to the insurance industry, and, therefore, national *health* *care* *reform* will have little impact on the underwriting cycle. Author-abstract.

 SO Nurse-Pract. 1992 May. 17(5). P 65, 69-72, 75.
 JT NURSE PRACTITIONER.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB Equal access to *health* *care* for all citizens is a hotly debated issue of the American *health* *care* system. Different plans for *reform* that would allow equal access to *health* *care* have been proposed, but few include nurses as key *health* *care* providers. To correct this oversight, a coalition of more than 60 national nursing and *health* *care* organizations has created Nursing's Agenda for *Health* *Care* *Reform,* a blueprint for restructuring the *health* *care* system. This article reviews the agenda within the framework of the ethical theory of distributive justice. Distributive justice allows for the allocation of *health* *care* resources in a manner that is fair but not necessarily equal for all. The agenda addresses the basic level of *health* *care* needed by all Americans and supports the provision of primary *care* by nurse practitioners. Nurse practitioners need to be aware of plans to *reform* the *health* *care* system and should be supportive of those plans that enhance nurse participation in the *health* *care* system. Nursing's Agenda for *Health* *Care* *Reform* is a plan that encourages the *health* *care* consumer's participation and promotes nursing *care* as the link between the consumer and the *health* *care* system. PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).
LG English (EN).
AB Issues and activities that dominated hospital pharmacy in 1991 are reviewed, and their relationship to political and economic trends of national and international importance is described. While rising costs, equitable reimbursement, and access to *care* continued to dominate the nation's *health-care* agenda in 1991, the growing interest in quality assurance was also noteworthy. *Health-care* *reform* will likely be a dominant issue during the current election year, and pharmacists are urged to play an active role in this restructuring process, both within their work settings and in their communities. Among the major concerns of hospital pharmacy in 1991 were the appropriate use of the new products of biotechnology, advances in computer and communications technology, and measuring and improving the quality of pharmaceutical *care.* Other issues highlighted in the literature included the need to articulate a mission statement concerning pharmaceutical *care,* the role of specialization in pharmacy practice, and the appropriate allocation of human resources. The literature of hospital pharmacy continues to provide insight into the progress of the profession and to serve as a benchmark that will gauge its future course. Author-abstract. 123 Refs.

JT ACADEMIC MEDICINE.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB There is now a great disparity in the United States between resources
going to the young, the nation's poorest age group, and to the
elderly, the wealthiest age group, who are absorbing a greater and
greater share of resources for *health* *care.* The author outlines
reasons that these imbalances in the groups' access to resources have
developed, and then demonstrates that, in the area of *health* *care*
reform, an entitlement program for the young is not the answer:
society must overcome its unwillingness and put into place a
universal *health* *care* system. Even with such a system, the *health*
care needs of the elderly will continue to grow and absorb more
resources, both because the percentage of elderly is rising and
because developments in medical technology continue to create new
treatment possibilities and expectations. Should the *health* *care*
needs of the elderly be allowed to absorb a more and more
disproportionate share of the nation's resources compared with the
resources used for the young? The author answers "No" and explains
why he thinks (1) that medicine should become more oriented toward
providing *care,* preventing premature death, and improving the quality
of people's lives for a reasonable span of years (for example, until
80) and less toward saving lives of the very old and incurably ill at
great cost; (2) that rationing and priority setting are inevitable
because of limited resources; and (3) that the claims of children may
on occasion need to be placed before those of the elderly. These
changes can be made only if Americans change their *health* *care* system
and some of their present values about the role of medicine.

AB The author discusses the need to create structural *reforms* in the nation's *health* *care* system, built around a consensus on workable, affordable solutions, the first of four needs in this area, and presents a set of principles that must frame the debate on *health* *care* *reform* (e.g., that *health* *care* must be accessible to all Americans). He also presents practical options that address the United States' most urgent *health* *care* concerns (e.g., making the cost of *health* insurance more affordable for small businesses). The second need is to preserve and strengthen the nation's biomedical research enterprise; the author outlines steps that are already under way to deal with this need (e.g., the development of a Biomedical Research Initiative in the Public *Health* Service and the allocation of funds for various research-connected activities). The third need is to increase the participation of minority youth in science and the *health* professions; the author outlines steps that are being taken to encourage such participation (e.g., helping historically black colleges and universities and funding training programs for training minority professionals in *health* *care*).* The last need discussed is to foster a culture of character: empowering citizens to take control of their own lives to eliminate costly debilitating illness before it strikes. For all these needs to be addressed successfully, it is crucial that the involvement of the academic *health* professions community and the community at large be expanded. Author-abstract.

AB No longer can the *health* *care* community and the politicians work separately as they usually did until just a generation ago. Now, with or without the frustrations involved, both groups need one another and must work together to fulfill their common goal of caring for people. The U.S. economy can no longer sustain the immense and mounting costs of *health* *care:* the system must change drastically before the end of the century or there will be revolution or a collapse of the system. For the first time, there is a strong constituency calling for *health* *care* *reform.* The politicians and the *health* *care* community must stop ignoring that constituency and instead work together on a *health* *care* bill to head off the coming crisis. Such a bill will exact sacrifices and compromises from all sectors, and must control costs and provide universal access to *health* *care.* The author outlines proposed bills and other activities that are now being considered, describes a bill that he has helped craft and introduce, and notes that the Bush administration has done an about-face and is now promising a *health* *care* bill. He challenges academic medicine to help produce more primary *care* physicians, gives examples of efforts that are fostering primary *care,* especially in rural areas, and explains why having more primary *care* physicians is vital and also a key to cost containment. He ends by again urging the *health* *care* community to participate in defining what can be done to avert the coming crisis and establish a workable and equitable *health* *care* system. Author-abstract.

AB This article explores the relationship between the Quarterly and the
contemporary history of *health* services research. Between 1977 and
1990 most of the articles in the Quarterly addressed the dominant
concerns of the growing constituency that identified with the newly
named field of *health* services research. However, the Quarterly also
reflected its editor's interest in an older tradition of *health* *care*
reform and public *health* in the United States and abroad. An
analysis of the articles published in the Quarterly in three periods
(1977-1981, 1981-1986, 1986-1990) reveals themes that received
consistent attention, others that received increasing attention, and
still others that were accorded diminished attention. This analysis
highlights the value of the Quarterly as a source of insight about
the individuals who have written for, edited, guided, and read it.

AB This report examines the role of the expert in the American *health*
care system, both as provider and administrative policymaker. It
shows that the guiding assumption of American *health* *care* policy, ie,
that the medical system can and should be managed by experts on
behalf of consumers and patients, does not hold up to scrutiny. It
also demonstrates that the important theme in American history of
placing authority and responsibility for action in the hands of the
individual has not been sufficiently influential in American *health*
care. Drawing on this theme and creating consumer competence and
responsibility in *health* *care* choices as the keys to *health* *care*
reform in the United States are advocated. Author-abstract. 21

 AB Occupational *health* nursing has evolved from a single dimension
 practice into a complex role providing primary *care,* *health*
 maintenance, and disease prevention programs at the worksite. The
 focus of the 1990s will be on managed *care,* *health* *care* *reform,* and
 competition for resources. Occupational *health* nurses are in a
 strategic position to foster the objectives set forth in Healthy
 People 2000. Occupational *health* nurses must take the lead in the
 development and implementation of cost effective *health* *care* programs
 at the worksite. Occupational *health* nurses must communicate and
 demonstrate the nature and value of their contributions; demonstrate
 their competencies; and become knowledgeable in all areas of
 occupational *health* and safety. They must acknowledge that they are
 leaders in workplace *health* and safety. Author-abstract.

 AB The organization and finance of *health* *care* in the United States are
 likely to change dramatically during the 1990s. During the first
 half of the decade, pro-competition strategies, which characterized
 the 1980s, are likely to continue. However, by the end of the
 decade, the country will probably adopt some form of national *health*

care. After briefly discussing both possibilities, this paper investigates their likely impact on the future practice of chiropractic in the United States, and concludes with some policy recommendations. Author-abstract. 125 Refs.

PT COMMENT (COM). EDITORIAL (EDI).
LG English (EN).
AB The human and social costs of the human immunodeficiency virus are mounting rapidly in the U.S. and abroad. It is likely that this disease will help catapult us into *health* *care* *reform* in the current decade. Hopefully, *health* services research on HIV disease will contribute to the debate on what the nature of this *reform* should be. We need to understand the implications of access barriers facing those with no insurance as distinct from those with public insurance. We must grapple with and understand the implications for estimating the costs of AIDS, of open-ended, publicly funded acute *care* for persons with HIV. Furthermore, we must understand the long-term *care* needs of chronically ill AIDS patients with frequent periodic life-threatening acute events and the optimum structure(s) necessary to provide such *care.* Above all, we must be sensitive to the rapidly evolving treatments for HIV and the fact that these can make cost projections completely obsolete almost before they are made. *Health* services research on HIV disease must, of necessity, focus on many of the traditional themes of our emerging discipline. At the same time, the fact that it is an infectious disease with an observable transformation into a chronic condition has implications for the way we study it and how we define the emergence of clinical disease.

This has implications for how we conduct *health* services research on the entity and may push us toward a new set of methodologies that borrow more from epidemiology than cost accounting.

AB There is reason for pessimism about the incorporation of prevention
into medical education. In addition to what might be called the
standard reasons for resistance to prevention, there are at least
three other structural barriers: the destabilization of the *health*
care system, the loss of interest in careers in primary *care,* and
preventive medicine's failure to adopt a far-reaching critique of
medicine and medical education. Only through linkages to progressive
health *care* *reform,* to primary *care,* and to the biopsychosocial model
can prevention achieve an important place in medical education.

Abstract

Stress is believed to activate sphingomyelinase to generate ceramide, which serves as a second messenger in initiating the apoptotic response. Conclusive evidence for this paradigm, however, is lacking. In the present study, we used a genetic approach to address this issue directly. We show that lymphoblasts from Niemann-Pick patients, which have an inherited deficiency of acid sphingomyelinase activity, fail to respond to ionizing radiation with ceramide generation and apoptosis. These abnormalities are reversible up on restoration of acid sphingomyelinase activity by retroviral transfer of human acid sphingomyelinase cDNA. Acid sphingomyelinase knockout mice also expressed defects in radiation-induced ceramide generation and apoptosis in vivo. Comparison with p53 knockout mice revealed that acid sphingomyelinase-mediated apoptosis and p53-mediated apoptosis are likely distinct and independent. These genetic models provide definitive evidence for the involvement of acid sphingomyelinase in one form of stress-induced apoptosis.

Title

[The relationship between respiratory system reactivity and neutrophil metabolism in hypoxia in persons subjected to ionizing radiation exposure]. [Russian]

Source

Radiatsionnaia Biologiia, Radioecologiia. 36(3):400-4, 1996 May-Jun.

Abstract

The group of 18 men exposed to radiation during amelioration work in the Chernobyl NPP was examined in the course of adaptation to intermittent hypoxia (rebreathing technique during 10 days of three daily 5-7 min sessions with 15 min break). The starting level of ventilatory response to hypoxic stimulus (HVR) did not differ from the one in persons living in non-contaminated areas. This hypoxic training (HT) caused the increase of HVR, activity of NADPH-oxidase and cationic protein content in neutrophils as well as various changes in myeloperoxidase activity. The correlation between respiration reactivity and deviations in neutrophil metabolism under HT was found.

Source

Radiatsionnaia Biologiia, Radioecologiia. 36(3):394-9, 1996 May-Jun.

Abstract

Free radical processes and some indices of antibacterial defense system

have been examined in 29 male residents of Chernobyl area during adaptation to periods of intermittent hypoxia. 18 men (the experimental group) were exposed to normobaric isocapnic progressive hypoxia during 10 days of three daily 5-7 min sessions with 15 min breaks, and 11 men (control group) were exposed to air breathing. All subjects were divided into two subgroups with initial high (1) and low (2) level of blood chemiluminescence (ChL). Patients of the 1 subgroup were characterized with high oxygen-generated activity of neutrophils (OGA) and high malondialdehyde (MDA) concentration. After hypoxic training (HT) there was a decrease of spontaneous and initiated ChL and MDA. Patients of the 2 subgroup were characterised with low level both spontaneous and initiated ChL, low MDA concentration and low phagocytosing activity of neutrophils. After HT there was significant rise of initiated ChL and MDA concentration up to normal level with the increasing of neutrophil phagocytosing activity. We suggest that HT causes the normalizing effect on free radical processes in subjects who were exposed to radiation influences.

Title

Decreased sensitivity to the cytogenetic effects of bleomycin in individuals occupationally exposed to ionizing radiation.

Source

Mutation Research. 354(1):81-6, 1996 Jul 5.

Abstract

In the present work, 12 individuals occupationally exposed to ionizing radiation and 11 unexposed ones were studied to determine the cytogenetic effect of a challenge dose of bleomycin on their phytohemagglutinin stimulated lymphocytes. After bleomycin treatment, the frequencies of chromatid breaks and gaps were significantly lower in the exposed population ($p < 0.025$ for both types of chromatid alterations). These results could indicate that occupational exposure to ionizing radiation can induce an adaptive response that can be detected by a subsequent treatment with bleomycin.

Title

Do human lymphocytes exposed to the fallout of the Chernobyl accident exhibit an adaptive response? III. Challenge with bleomycin in lymphocytes from children hit by the initial acute dose of ionizing radiation.

Source

Mutation Research. 354(1):77-80, 1996 Jul 5.

Abstract

In the present paper, we report data on the possible adaptive response, induced in vivo by exposure to ionizing radiation to a challenge treatment with the radiomimetic glycopeptide bleomycin (BLM). Lymphocytes from children living in Pripjat at the time of the Chernobyl accident, and thus hit by the initial acute dose of ionizing radiation, were treated for the last 5 h of culture with 0.004 U/ml BLM. Significantly lower chromosome damage was found only in lymphocytes from children who, independently of the initial acute exposure to ionizing radiation, still showed a 137Cs internal contamination, due to persistent continuous exposure to low doses of radiation. The present results indicate that past exposure to acute high dose of ionizing radiation does not interfere with resistance to BLM which is related to internal contamination.

Title

Characterization of the GADD45 response to ionizing radiation in WI-L2-NS cells, a p53 mutant cell line.

Source

Mutation Research. 352(1-2):79-86, 1996 Jun 10.

Abstract

We have previously reported that WI-L2-NS, a human lymphoblastoid cell line, has very high basal levels of GADD45 mRNA and protein in spite of a p53 mutation at amino acid 237. Regardless of the amount of Gadd45 in this cell line, no growth suppression activity was detected. We report here that in WI-L2-NS, the mutated p53 protein adopts predominantly a wild type (wt) conformation and binds to the p53 binding site in the GADD45 third intron. In this cell line, the already high levels of mutated p53 protein can be induced further by ionizing radiation (IR) but the response of the p53 downstream effector genes is altered. Induction of GADD45 and CIP1/WAF1 is reduced compared to p53 wt cell lines but is still substantially higher than the average fold induction obtained from 39 p53 mutant cell lines. Induction of the MDM2 gene was not detected in WI-L2-NS following IR. The induction pattern of the three p53 effector genes by the alkylating agent methylmethane sulfonate (MMS) was also attenuated in WI-L2-NS cells. In TK6 cells, a WI-L2-NS sister cell line having a p53 wt genotype, the induction of the p53 downstream effectors is normal, i.e. induced, both at the protein and the mRNA levels. These results indicate that the DNA binding activity of the mutated p53 protein in WI-L2-NS might be responsible, at least in part, for the high basal levels of GADD45 but can not mediate the full induction of the p53 downstream effector genes. The reason(s) for the inability of Gadd45 to suppress growth in this cell

line remains however unknown.

Title

UV- and gamma-irradiation-induced DNA single-strand breaks and their repair in human blood granulocytes and lymphocytes.

Source

Mutation Research. 352(1-2):31-8, 1996 Jun 10.

Abstract

Ionizing irradiation and UV-irradiation cause DNA damage. Ionizing irradiation induces single-strand breaks, much less abundantly double-strand breaks, alkali-labile sites, and various oxidized purines and pyrimidines. UV-irradiation, on the other hand, causes cyclobutane pyrimidine dimers, (6-4) photoproducts, and various monomeric base damages. The deposition of energy in DNA may result directly in single-strand breaks (predominant form after ionizing radiation), or the strand breaks may be generated during the repair process (predominant form after UV-irradiation). We investigated the formation and repair of DNA single-strand breaks in human blood granulocytes and lymphocytes by the single-cell gel electrophoresis or comet assay. The induction and repair of DNA lesions by gamma-irradiation was comparable in human blood granulocytes and lymphocytes. The finding is consistent with the expression of the pertinent base excision repair proteins in these cells. In contrast to gamma-irradiation, fewer single-strand breaks were observed immediately after UV-irradiation; the maximum number of breaks were seen when the cells were incubated for 30-60 min. After an incubation period of 150 min, a significant reduction of single-strand breaks was noted. It is conceivable that the first 30-60 min represented a period during which the incision-excision phase of nucleotide excision repair (NER) predominated. After that, strand joining was dominant, evidently representing the synthesis and ligation phase of NER. These results indicate that the approx. 30 different polypeptides required for complete NER are functional in these mature blood cells. This is the first demonstration of the expression of global NER in human granulocytes.

Title

Accelerated telomere shortening in ataxia telangiectasia.

Source

Nature Genetics. 13(3):350-3, 1996 Jul.

Abstract

Ataxia telangiectasia (AT) is characterized by neurological deterioration, immunodeficiency, spontaneous chromosomal instability, hypersensitivity to ionizing radiation, predisposition to cancer, particularly T cell leukaemia and lymphoma, and premature ageing. The most commonly observed defect affecting telomeres in humans is telomeric fusions, particularly in T lymphocytes in AT patients. Rarely, some tumour cells, like senescent cells, have dicentric chromosomes that may arise as a result of telomeric sequence loss. We show that the AT mutation in the homozygous state confers a predisposition to accelerated telomere shortening with increasing age in peripheral blood lymphocytes (PBLs), which may be linked to premature senescence. We also show that telomeric fusions are associated with large (> 90%) preleukaemic translocation clones in T cells. We propose that these fusions may result from a compound effect of accelerated telomere shortening, together with a growth advantage of cells in large clones which leads to further telomere loss. Fusions are not observed in leukaemic cells in these patients. There is no evidence that either accelerated telomere loss per se or telomeric fusions are important in tumourigenesis. Telomerase is present in both normal and AT lymphocytes and so neither telomere shortening nor telomeric fusions can be explained by the absence of telomerase.

[The cell cycle patterns of the hemopoietic cells under the action of ionizing radiation]. [Russian]

Source

Gematologiya i Transfuziologiya. 40(6):25-9, 1995 Nov-Dec.

Abstract

The analysis of changes in bone marrow cell cycle induced by ionising radiation in animals and humans in comparison with myelogram evidence on postradiation death of myelocaryocytes shows that radiation is responsible for pronounced dose-dependent shifts in cell cycle early after radiation prior to postradiation cell death. These phenomena are considered in light of new hypothesis on the existence of cell cycle regulation system and initiation of apoptosis at the cell level.

Title

Inverse dose-rate effect for mutation induction by gamma-rays in human lymphoblasts.

Source

International Journal of Radiation Biology. 69(5):555-63, 1996 May.

Abstract

In order to define further the effects of differences in recombinational proficiency on cell survival and mutation by ionizing radiation, we exposed the syngenic cell lines TK6 and WTK1 to continuous low dose-rate gamma-irradiation. We previously demonstrated that acute X-ray exposure results in lower survival and lower mutation induction at both the thymidine kinase (tk) and the hypoxanthine-guanine phosphoribosyltransferase (hprt) loci in TK6 cells compared with WTK1 cells. These differences were attributed in part to reduced levels of recombination in the TK6 line relative to WTK1. Using a low dose rate ¹³⁷Cs irradiator, we exposed asynchronous growing populations of these cells to gamma-rays at 14.3, 6.7 and 2.7 cGy/h. Both cell lines exhibited a dose-rate effect on survival. Compared with acute doses, the low dose-rates also protected against mutation induction at the hprt locus in WTK1, but protection was inversely related to dose-rate. There was also a slight inverse dose-rate effect in TK6, with mutation induction at the lowest dose-rate exceeding that at acute exposures.

Title

Deregulated apoptosis in ataxia telangiectasia: association with clinical stigmata and radiosensitivity.

Source

Cancer Research. 56(6):1400-4, 1996 Mar 15.

Abstract

Ataxia telangiectasia (AT) is a recessive genetic disease featuring neurodegeneration, immunodeficiency, chromosomal instability, radiation hypersensitivity, and increased predisposition to cancer. Reduced or delayed induction of the tumor suppressor protein p53 after gamma-irradiation was reported. These characteristics may be compatible with an inability to correctly regulate apoptosis. We show here that AT lymphocytes and EBV-transformed lymphoblasts demonstrate a significantly higher level of spontaneous apoptosis, whereas ionizing radiation-induced apoptosis is reduced compared to normal cells. However, neither AT nor normal primary fibroblasts undergo apoptosis after irradiation. Consequently, we conclude that the radiosensitivity of the AT cells is not related to an increased apoptotic response. Finally, we show that SV40-transformed AT fibroblasts undergo gamma-ray-induced apoptosis, while SV40-transformed normal cells do not. This result raises the question of the physiological relevance of the latter cellular model with respect to the AT phenotype.

Title

Induction and persistence of cytogenetic damage in mouse splenocytes following whole-body X-irradiation analysed by fluorescence in situ hybridization. I. Dicentrics and translocations.

Source

International Journal of Radiation Biology. 69(4):437-46, 1996 Apr.

Abstract

Chromosome translocations (stable aberrations) can persist longer during cellular proliferation than dicentrics (unstable aberrations). It is important to know the kinetics of the elimination of dicentrics and to what extent translocations persist in an in vivo cell population after irradiation. The female Swiss mouse were used to study the induction and persistence of dicentrics and translocations in splenocytes up to 112 days after exposure to 2 Gy whole-body X-irradiation. Metaphase spreads at different time intervals were analyzed by fluorescence in situ hybridization (FISH) using chromosome-specific DNA libraries for chromosomes 1, 11 and 13. The frequencies of dicentrics and translocations appear to be equal immediately after irradiation. Frequencies of dicentrics decreased exponentially with time according to the relationship $D = ae(-kt)$. The rate of elimination was faster in the early period (days 0-14) than in the later period ($> \text{ or } = 14$ days). The frequency of translocations was constant in the period 0-7 days and then decreased linearly or exponentially. For the whole period, the trend is highly significant. As mouse chromosome painting probes are becoming available and by using FISH, an in vivo mouse model for the analysis of translocations has become feasible. As translocations are involved in carcinogenesis and genetic disorders, risk estimation for induction of translocations by ionizing radiation can be made with greater confidence and extrapolated to the human situation.

Title

Physical and functional interactions between Lyn and p34cdc2 kinases in irradiated human B-cell precursors.

Source

Journal of Biological Chemistry. 271(11):6389-97, 1996 Mar 15.

Abstract

Exposure of human B-cell precursors (BCP) to ionizing radiation results in cell cycle arrest at the G2-M checkpoint as a result of inhibitory tyrosine phosphorylation of p34cdc2. Here, we show that ionizing radiation promotes physical interactions between p34cdc2 and the Src

family protein-tyrosine kinase Lyn in the cytoplasm of human BCP leading to tyrosine phosphorylation of p34cdc2. Lyn kinase immunoprecipitated from lysates of irradiated BCP as well as a full-length glutathione S-transferase (GST)-Lyn fusion protein-phosphorylated recombinant human p34cdc2 on tyrosine 15. Furthermore, Lyn kinase physically associated with and tyrosine-phosphorylated p34cdc2 kinase in vivo when co-expressed in COS-7 cells. Binding experiments with truncated GST-Lyn fusion proteins suggested a functional role for the SH3 rather than the SH2 domain of Lyn in Lyn-p34cdc2 interactions in BCP. The first 27 residues of the unique amino-terminal domain of Lyn were also essential for the ability of GST-Lyn fusion proteins to bind to p34cdc2 from BCP lysates. Ionizing radiation failed to cause tyrosine phosphorylation of p34cdc2 or G2 arrest in Lyn kinase-deficient BCP, supporting an important role of Lyn kinase in radiation-induced G2 phase-specific cell cycle arrest. Our findings implicate Lyn as an important cytoplasmic suppressor of p34cdc2 function.

Title

Monitoring hprt mutant frequency over time in T-lymphocytes of people accidentally exposed to high doses of ionizing radiation.

Source

Environmental & Molecular Mutagenesis. 27(3):165-75, 1996.

Abstract

Modern technologies have provided the opportunity to monitor mutations in people in vivo. The subjects of this study were accidentally exposed to ¹³⁷Cesium in a radiological accident that occurred in September 1987 in Goiania, Brazil, during which more than 150 people received doses greater than 0.1 Gy and as high as 7 Gy. The objective of this study was to determine how long the hprt mutant T-cells in the peripheral blood contribute to mutant frequency by examining the time-course of the T-lymphocyte response to ionizing radiation. This report describes the results obtained over a period of 2.3 to 4.5 years subsequent to the accident, from 11 subjects with doses ranging from 1 to 7 Gy, and from nine control subjects selected from the same population. The mean In MF (+/- SE) of the control group was 2.5 (+/- 0.2) + In10(-6). The exposed group had a significantly increased mutant frequency; the mean In MF (+/- SE) were 3.3 (+/- 0.3) + In10(-6), 2.8 (+/- 0.2) + In10(-6), and 2.3 (+/- 0.2) + In10(-6), in the years 1990-1992 respectively. Based on the decline of mutant frequency and using Buckton's models [Buckton et al. (1967): Nature 214:470-473], we demonstrated that mutant T-cells have a short-term memory with a half-life of 2.1 years. This relatively short half-life limits the effective use of the hprt assay as the method of choice to monitor past exposure. The data also demonstrate a positive correlation with age, and an inverse correlation with plating efficiency.

Title

Effects of low-dose (2 cGy) X-ray on cell-cycle kinetics and on induced mitotic delay in human lymphocyte.

Source

Mutation Research. 351(2):193-7, 1996 Apr 13.

Abstract

Experiments were carried out with human lymphocytes to test the effect of low-dosage X-ray irradiation (2 cGy) on cell-cycle kinetics and on the mitotic delay induced by the conditioning pretreatment alone or by a subsequent high dose of X-ray. All the tests were performed using lymphocytes from two donors who had previously displayed considerable differences in the interaction between a low and a high dose of ionizing radiation. A dose of 2 cGy led to significant variations in mitotic indices (MI) which differed for the two donors in relation to variations in the times of irradiation and fixation after stimulation with PHA. Moreover in one of the two donors 4-6 h after challenge the pretreated cultures have a higher MI than the controls; on the other hand, conditioning treatment alone induces in the other donor an extension of both G2 and of the time taken by cells in S at the time of challenge to reach mitosis. These findings could in the future provide some insight into the problem of the variability of the adaptive response in human lymphocytes.

Title

Radiation-induced chromosomal aberrations among TENORM workers: among- and ilmenite-processing workers of Malaysia.

Source

Mutation Research. 351(2):157-61, 1996 Apr 13.

Abstract

The usefulness of peripheral human lymphocytes as a bioindicator for ionizing radiation effect was tested in a survey of Malaysian workers in two industries producing technologically enhanced naturally occurring radioactive material (TENORM). Workers in amang processing plants who have been with the plant for an average of 12.9 years and who were exposed to radioactive dust showed significantly higher frequencies of chromosomal aberration compared to control and even ilmenite-processing workers. Such frequency was not significantly different between workers in ilmenite-processing plant and control. The differences in duration of employment, occupational hygiene, together with the difference in the percentage of 'old' and 'new' aberrations among the groups sampled were

used to explain the high chromosomal aberration frequency among among workers. The presence of significantly high chromosome damage (dicentric and fragments) in workers who were chronically exposed to doses below 50 mSv per year or 20 mSv per year averaged over 5 years (ICRP, 1991) provided additional experimental data on the dose-effect relationship at these low-dose ranges. The results confirm the usefulness of using human lymphocytes as a bioindicator for chronic exposure to ionizing radiation and in cases where physical radiation detectors are not available.

Title

Contrasting mechanisms of the myeloprotective effects of interleukin-1 against ionizing radiation and cytotoxic 5-fluorouracil.

Source

Radiation Research. 145(5):624-31, 1996 May.

Abstract

Pretreatment with a single dose of interleukin-1 (IL-1) counteracts the myelosuppressive effects of radiation. In contrast, multiple doses are required to protect against several cytoablative drugs, suggesting different mechanisms. We examined the possibility that myeloprotection is due to IL-1-induced cycling of primitive progenitor cells. First, we evaluated the effect of the time between administration of IL-1 and 5-fluorouracil (5-FU), which kills cycling cells but spares quiescent early progenitors, on their interaction. Pretreatment with a single dose of IL-1 resulted in the death of mice treated with 5-FU provided IL-1 was given 18 h, but not 4 or 48 h, prior to administration of sublethal doses of 5-FU. Second, evaluation of primitive hematopoietic progenitor cells, 13-day spleen colony-forming units (CFU-S) and CFU with high proliferative potential revealed that treatment with 5-FU 18 h after administration of IL-1 results in reduction of CFU-S by 98% and of CFU with high proliferative potential by 65%, but only a 7 and 10% reduction, respectively, at 48 h. Third, in contrast to protection from death by pretreatment with a single dose of IL-1 at 24 h, two injections of IL-1 at 72 and 24 h before irradiation abrogated such protection. Similarly, the toxicity of 5-FU to progenitor cells was reduced when two injections of IL-1 were administered 48 h apart. This correlates with the time of up-regulation in the bone marrow cells of TGF-beta. These findings suggest that, depending on the schedule of treatment, administration of IL-1 may result in cycling of primitive progenitors, to protect against radiation, and may cause inhibition of cycling to protect against chemotherapeutic drugs.

Title

Modulation of radiation-induced chromosomal damage by inhibitors of DNA repair and flow cytometric analysis in ataxia telangiectasia cells with 'intermediate radiosensitivity'.

Source

Mutagenesis. 10(6):523-9, 1995 Nov.

Abstract

The relationship between repair processes and chromosomal aberrations and X-ray-induced cell cycle perturbations were investigated in ataxia telangiectasia (AT) cells with 'intermediate' (AT-INT) and 'classical' radiosensitivity. In the cytogenetic experiments, three AT-INT lymphoblastoid cell lines were X-irradiated in G2-phase and incubated in the presence of inhibitors of DNA polymerases alpha/delta/epsilon (cytosine arabinoside, aphidicolin, 10% v/v DMSO), ribonucleotide reductase (hydroxyurea) and presumed inhibitors of protein kinases (caffeine). Flow cytometric analysis was performed in cells harvested 20 h after irradiation and stained with either propidium iodide or antibody against 5-bromodeoxyuridine in order to investigate cell cycle distribution focusing on G2/Mphase accumulation. From our data it appears that: (i) chromosomal sensitivity to radiation in AT does not always reflect clinical features; (ii) the effects of DNA repair inhibitors are inversely correlated with chromosomal radiosensitivity; and (iii) radiation-induced G2/M phase accumulation is a feature of AT cells and not necessarily correlated with cellular and chromosomal sensitivity to ionizing radiation.

Title

Haematopoietic growth factors in the treatment of therapeutic and accidental irradiation-induced bone marrow aplasia [see comments].
[Review]

Comments

Comment in: Int J Radiat Biol 1995 Oct;68(4):487-90

Source

International Journal of Radiation Biology. 67(2):103-17, 1995 Feb.

Abstract

Bone marrow aplasia is one of the main syndromes following a high dose accidental exposure of ionizing radiation. Although both transfusion and bone marrow transplantation have been used with some success since the first treatments of patients, other therapeutic strategies are needed. The strategies involving haematopoietic growth factors for the treatment of radiation victims have been explored in vivo mainly in animal models and

it is hoped that new therapeutic regimens will be elucidated from such approaches. The growth factors stimulate proliferation and/or differentiation of haematopoietic progenitor cells and possible stem cells. Furthermore, they act on the functions of mature cells. They now have specific uses in haematology, related to their role in the regulation of growth and differentiation of haematopoietic progenitor cells. The results of the clinical trials, performed with numerous patients and often randomized bring important clues about what to expect from growth factor therapy. Other factors are only entering the preclinical or clinical trials now. Although numerous in vitro or in vivo experiments suggest a benefit from their effects, their possible uses in therapy are still questionable. Some growth factors have already been used for the treatment of accidental radiation-induced aplasia and lessons have been learned from their medical management and follow-up. [References: 99]

Title

Both in vitro and in vivo irradiation are associated with induction of macrophage-derived fibroblast growth factors.

Source

Clinical & Experimental Immunology. 103(1):67-73, 1996 Jan.

Abstract

Fibrosis in the lung directly underlying the field of irradiation is an almost universal long term sequelae of thoracic irradiation. It is assumed to represent the consequence of direct damage to local tissues and/or vascular endothelium by ionizing radiation. This view, however, is not in keeping with our current understanding of fibrotic processes, which suggest that growth factors for fibroblasts (including platelet-derived growth factor (PDGF), insulin-like growth factor I (IGF-I)) and cytokines stimulating collagen synthesis (notably transforming growth factor-beta) are largely responsible for this process. Since a major source of these factors is the macrophage, present in large numbers within the lung, it appeared possible that radiation-induced fibrosis might be mediated by similar mechanisms. Therefore, a study was designed to determine, first, whether in vitro irradiation of mononuclear phagocytes could induce the release of growth factors for fibroblasts. Second, we wished to ascertain whether these same growth factors might also be secreted by bronchoalveolar cells from humans who had undergone in vivo thoracic irradiation. The results of this study indicate that irradiation of a number of different types of mononuclear phagocytes resulted in the dose-dependent synthesis and release of several growth factors for fibroblasts, including PDGF, tumour factor-alpha (TNF-alpha) and IGF-I. Further, cells obtained by bronchoalveolar lavage from patients undergoing thoracic radiation spontaneously released PDGF following irradiation. These findings strongly support the contention that synthesis and release

of macrophage-derived growth factors for fibroblasts (particularly PDGF and IGF-I) occur after thoracic irradiation and play a significant role in the pathogenesis of irradiation-induced pulmonary fibrosis in humans.

Title

8-Oxo-2'-deoxyguanosine level in lymphocytes DNA of cancer patients undergoing radiotherapy.

Source

Cancer Letters. 99(1):93-7, 1996 Jan 19.

Abstract

We analyzed the level of 8-oxo-2'-deoxyguanosine in lymphocytes DNA of cancer patients undergoing radiotherapy. The results of this work indicate that exposure of cancer patients to therapeutic doses of ionizing radiation causes significant increase of the amount of 8-oxo-dG in DNA isolated from their lymphocytes.

[Dna repair activity in children exposed to small doses of ionizing radiation as a result of the accident at the Chernobyl nuclear power station]. [Russian]

Source

Genetika. 31(10):1433-7, 1995 Oct.

Abstract

The repair activity of DNA was studied by variola vaccine virus reactivation and induced mutagenesis tests in the peripheral blood lymphocytes of children living in areas with an increased level of ionizing radiation due to breakdown at the Chernobyl' nuclear power station. A more profound repair disturbance was revealed in children living on strictly controlled territories and born after the disaster, compared to those born before it, and children living in areas where the radiation level does not exceed background values. The disturbances were characterized by increased induced mutagenesis and decreased reactivation of the variola vaccine virus. No changes in the degree of DNA repair synthesis were registered in any of the groups studied.

Title

Follow up study of chromosome aberrations in lymphocytes in hospital workers occupationally exposed to low levels of ionizing radiation.

Source

Mutation Research. 335(3):245-51, 1995 Dec.

Abstract

In the present study we analyzed and followed up on the cytogenetic effects of low levels of ionizing X-radiation on hospital workers at 72 h cultures. Samples of peripheral blood were collected from 10 hospital workers exposed to 1.84 mSv/year, and from 10 non exposed individuals, who were screened simultaneously and used as controls. The chromosomes were prepared using standard techniques. After 12 months, we undertook a second evaluation, this time with exposure to the same workers of 1.67 mSv/year. We observed 100 metaphases per subject, and there was a high percentage of altered metaphases (29.2% in the first sample and 26% in the second samples) The chromosome analysis in the second mitotic division, show aberrations such as gaps, breaks and acentric fragments, as well as other alterations such as dicentrics and rings, as well as chromosome variants (double minutes) in the exposed workers vs. the controls, and the difference was statistically highly significant ($p < 0.001$). There is no statistically significant difference between the first sample of exposed workers with the second one ($p > 0.05$). The findings in this study are interesting, because the workers were exposed to doses well below the accepted standards for exposure to radiations. Because of these unusual findings, our results could have potentially major consequences on our views on standards of exposure to radiation.

Title

Do human lymphocytes exposed to the fallout of the Chernobyl accident exhibit an adaptive response? 2. Challenge with bleomycin.

Source

Mutation Research. 332(1-2):39-44, 1995 Nov.

Abstract

The present study concerns the possible adaptive response, induced in vivo by a continuous exposure to ionizing radiations, to a challenge treatment with the radiomimetic glycopeptide bleomycin (BLM). Lymphocytes from children contaminated as a consequence of Chernobyl accident were treated for the last 5 h of culture with 2.5 micrograms/ml BLM. The induced chromosome damage was significantly lower than that found with the same treatment in lymphocytes from control children. This hyposensitivity to BLM was still present if, 1 h after the addition of the drug, inhibitors

of the enzymes involved in DNA repair, such as 3-aminobenzamide (2 mM), or aphidicolin (0.4 microM) or 3-dideoxythymidine (5 mM) were added to the cultures. The resistance to BLM in lymphocytes from contaminated children seems to be related to a mechanism upstream in respect to the activities of enzymes involved in the DNA repair and specifically linked to the action of this drug. This is consistent with the different response found when the cells were challenged with ionizing radiation in vitro, as reported in the accompanying paper (L. Padovani, L. et al. (1995) Mutation Res., this issue).

Title

Do human lymphocytes exposed to the fallout of the Chernobyl accident exhibit an adaptive response? 1. Challenge with ionizing radiation.

Source

Mutation Research. 332(1-2):33-8, 1995 Nov.

Abstract

Several studies suggest that cells appear to become less susceptible to the induction of radiation damage, and in particular of chromosome and chromatid aberrations in short-term cultures of human lymphocytes, when a challenge exposure to ionizing radiation is preceded by a low 'adaptive' dose. Contradictory results have been reported on the conditions under which the phenomenon can be evidenced. In the present work, circulating lymphocytes of 13 children contaminated from the fallout after the Chernobyl accident were tested for their capability to exhibit an adaptive response in experiments in which the challenge dose was administered to stimulated lymphocytes in the S-G2 phase. Furthermore, the possible influence of 3-aminobenzamide, an inhibitor of poly(ADP-ribose) polymerase, was also investigated. Our results indicate that, at least in the instance of the end-point here used (chromosome and chromatid aberrations, the former resulting possibly from the Cs burden), human lymphocytes, chronically exposed to low doses from fallout, do not exhibit any decreased susceptibility to ionizing radiation. However, as reported in the accompanying paper, the same samples appear to show an 'adaptive' response when exposed to a challenge treatment with bleomycin (B. Tedeschi et al., 1995, this issue).

Title

The single cell gel electrophoresis/comet assay: a potential tool for detecting radiation-induced DNA damage in humans. [Review]

Source

Stem Cells. 13 Suppl 1:207-14, 1995 May.

Abstract

This review evaluates the applicability of the single cell gel (SCG)/comet assay as a tool for the biomonitoring of individuals accidentally, environmentally or occupationally exposed to ionizing radiation. This technique detects single-strand DNA breaks, alkali-labile damage, incomplete excision repair sites and DNA:DNA crosslinking at the level of the individual cell. The advantages of this technique include: (a) data are collected at the level of the individual cell, providing information on the intercellular distribution of damage and repair; (b) only small numbers of cells are required (i.e., only a few thousand); (c) virtually any eukaryotic cell population can be used; and (d) the assay is relatively sensitive (detection limit of 5 cGy gamma rays in human lymphocytes), simple and cost effective. What the assay lacks is specificity for radiation-induced DNA damage. However, the possibility of identifying types of DNA damage specific for ionizing radiation in selected subtypes of cells may be feasible. While additional research is required before the SCG assay can readily be applied as a standard biomonitoring tool for exposure to ionizing radiation, the data collected thus far support a conclusion that such research is clearly warranted. Title

DNA sequence analysis of HPRT- mutants induced in human lymphoblastoid cells adapted to ionizing radiation.

Source

Radiation Research. 144(2):181-9, 1995 Nov.

Abstract

Radioadaptation to the mutagenic effect of ionizing radiation by pre-exposure of human cells to a low dose has been shown to decrease the proportion of HPRT- mutants of the deletion type. To determine whether point mutations would be affected by the adaptive treatment, the molecular nature of mutations induced after exposure to low, high or low plus high doses was established. DNA sequencing of 38 point mutants which still expressed mRNA was performed using reverse transcription/polymerase chain reaction amplification. Under all conditions, base substitutions were the most common mutational event (range 72-80%), the remainder being frameshift and small deletions. The types and proportions of base changes did not appear to be differentially modified. A clustering of mutations was observed in exon 8, independently of the radiation protocol. About 40% of the mutants exhibited incorrect splicing of mRNA. The lack of striking modifications between the different molecular spectra of point mutations suggests that the low-dose pre-exposure does not affect the production and/or the processing of lesions leading to point mutations. Thus the highly significant effect triggered by the low dose is the preferential reduction of deletion-type mutations. In view of the actual small data set, definitive conclusions will be drawn only when our observations are confirmed or can be generalized to human endogenous loci other than the HPRT locus, which is particularly prone to the recovery of deletion-type mutations.

Title

Assessment of two protocols for the human lymphocyte cytokinesis-blocked micronucleus assay.

Source

Mutagenesis. 10(4):375-7, 1995 Jul.

Abstract

This study indicated that by adding cytochalasin B (6 micrograms/ml) at 24 h, the lymphocyte culture time for micronucleus (MN) assay could be shortened to 64 h. In both unirradiated and ex-vivo irradiated (2 Gy) lymphocytes from three populations, we found that the differences in MN yield obtained by our modified cytokinesis-blocked time frame and that recommended by Fenech and Morley (1985) were insignificant ($P = 0.66-0.87$). We believe that the shorter assay time may enhance the applicability of MN assay for the rapid assessment of ionizing radiation overexposures.

Title

Sizing highly fragmented DNA in individual apoptotic cells using the comet assay and a DNA crosslinking agent.

Source

Experimental Cell Research. 221(1):19-26, 1995 Nov.

Abstract

TK6 human B lymphoblast cells exposed to ionizing radiation undergo apoptosis in a time and dose-dependent manner. The resulting highly fragmented DNA is easily detected using the comet assay, a sensitive microscopic gel electrophoresis method capable of measuring DNA strand breaks in individual cells. The degree of DNA fragmentation may be indicative of different stages in the fragmentation process, responses to different agents, and/or cell type-dependent differences. In an effort to determine the number of breaks present in each apoptotic cell, we first applied a DNA-crosslinking agent, mechlorethamine, to TK6 cells containing a known number of DNA double-strand breaks produced by X rays. As the concentration of mechlorethamine increased, crosslinked DNA was less able to migrate during gel electrophoresis. Exposure of TK6 cells to 5 microM mechlorethamine prior to irradiation with 20 Gy was sufficient to "hide" the presence of these breaks by preventing DNA from migrating during electrophoresis. However, in apoptotic TK6 cells, it was necessary to apply a dose of mechlorethamine several times higher in order to produce a similar degree of inhibition of DNA migration. Calibrations using either the alkaline or neutral comet assays indicate that the average DNA fragment size in apoptotic TK6 cells is about 50 kb. Even in cells containing only 10-20% of the original amount of DNA, the remaining fragments still averaged about 50 kb, indicating that fragmentation to much smaller sizes occurs in some parts of the genome before others. When Chinese hamster V79 cells were exposed to hyperthermia (45 degrees C for 20 min), necrosis was induced over a period of several days. The size of DNA fragments in these cells was considerably larger (200-400 kb) and heterogeneity in appearance of comets was larger than observed for TK6 cells. This crosslinking method may be useful in discriminating cells dying by apoptosis from cells damaged or dying by other mechanisms.

Title

Oxidation of thymine to 5-formyluracil in DNA: mechanisms of formation, structural implications, and base excision by human cell free extracts.

Source

Biochemistry. 34(45):14758-64, 1995 Nov 14.

Abstract

Oxidative agents produce several different types of base modifications in

DNA, and only a few of these have been properly characterized with respect to mechanisms of formation and biological implications. We have established a procedure using neutral thermal hydrolysis and reverse phase high-performance liquid chromatography to determine the content of the oxidation product 5-formyluracil (5-foU) in DNA. With this method, it is shown that 5-foU residues are formed with high frequency from thymine by quinone-sensitized UV-A photooxidation. Since 5-foU is also induced by ionizing radiation, it appears to be formed under conditions where thymidine radical cations are generated and react with molecular oxygen. It was previously shown that 5-foU is formed directly from [methyl-3H]thymine residues in radioactively labeled DNA by two consecutive transmutations of 3H to 3He. The theoretical basis for the kinetics of such conversion is presented in this paper, and the calculated yields are confirmed experimentally by measuring the content of 5-foU in [methyl-3H]thymine-labeled DNA aged for different time periods. Such DNA contains virtually only 5-(hydroxymethyl)uracil and 5-foU, apart from normal bases, and is therefore very useful for the investigation of repair enzyme activities involved in the repair of 5-foU-containing DNA. Using this substrate, a DNA glycosylase activity was identified in human cell extracts for the removal of 5-foU.(ABSTRACT TRUNCATED AT 250 WORDS)

Title

Human cDNA clones that modify radiomimetic sensitivity of ataxia-telangiectasia (group A) cells.

Source

Somatic Cell & Molecular Genetics. 21(2):99-111, 1995 Mar.

Abstract

Genes responsible for genetic diseases with increased sensitivity to DNA-damaging agents can be identified using complementation cloning. This strategy is based on in vitro complementation of the cellular sensitivity by gene transfer. Ataxia-telangiectasia (A-T) is a multisystem autosomal recessive disorder involving cellular sensitivity to ionizing radiation and radiomimetic drugs. A-T is genetically heterogeneous, with four complementation groups. We attempted to identify cDNA clones that modify the radiomimetic sensitivity of A-T cells assigned to complementation group [A-T(A)]. The cells were transfected with human cDNA libraries cloned in episomal vectors, and various protocols of radiomimetic selection were applied. Thirteen cDNAs rescued from survivor cells were found to confer various degrees of radiomimetic resistance to A-T(A) cells upon repeated introduction, and one of them also partially influenced another feature of the A-T phenotype, radioresistant DNA synthesis. None of the clones mapped to the A-T locus on chromosome 11q22-23. Nine of the clones were derived from known genes, some of which are involved in

cellular stress responses. We concluded that a number of different genes, not necessarily associated with A-T, can influence the response of A-T cells to radiomimetic drugs, and hence the complementation cloning approach may be less applicable to A-T than to other diseases involving abnormal processing of DNA damage.

Title

Variability in adaptive response to low dose radiation in human blood lymphocytes: consistent results from chromosome aberrations and micronuclei.

Source

Mutation Research. 348(1):45-50, 1995 Sep.

Abstract

The frequencies of chromosome aberrations and micronuclei were evaluated to assess the induction of adaptive response to low dose ionizing radiation in each of the blood samples collected from eight different individuals. Following stimulation with phytohemagglutinin, the cells were exposed to an adaptive dose of 1 cGy X-radiation at 24 hours and a challenge dose of 150 cGy gamma radiation at 48 hours. Lymphocytes were fixed at 54 hours to examine the incidence of chromosome aberrations and at 72 hours to examine the frequency of micronuclei in cytokinesis-blocked binucleated cells. Lymphocytes from five donors, i.e., "responders", exhibited the induction of adaptive response; their lymphocytes, which were pre-treated with 1 cGy had significantly fewer chromosome aberrations and micronuclei induced by the challenge dose of 150 cGy gamma radiation, as compared to the cells which did not receive the pre-treatment with 1 cGy. Such an induction of adaptive response was not observed in the remaining three donors, i.e., "non-responders"; the incidence of chromosome aberrations and micronuclei induced by the challenge dose of 150 cGy was not significantly different between the cells which were pre-exposed and un-exposed to 1 cGy. In all eight individuals, there was a strong positive correlation between the incidence of chromosome aberrations and micronuclei. Hence, whether or not an individual is a 'responder' or 'non-responder' could be assessed using either chromosome aberrations or micronuclei as the end-point. The overall pattern of response confirms the heterogeneity in adaptive response between individuals to ionizing radiation, which may in part be genetically controlled. Because of the simplicity of the technique and rapid assessment of the binucleated cells, we suggest the use of the micronucleus test as an alternative procedure in large scale population studies related to the adaptive response.

Title

scid cells are deficient in Ku and replication protein A phosphorylation by the DNA-dependent protein kinase.

Source

Molecular & Cellular Biology. 15(10):5700-6, 1995 Oct.

Abstract

Cell mutants of the Ku nuclear DNA-binding complex are ionizing radiation sensitive and show V(D)J recombination defects. Ku binds and activates a catalytic subunit of DNA-dependent protein kinase (DNA-PK), although the substrates for DNA-PK are unknown. We found that scid cell extracts were deficient in Ku phosphorylation by DNA-PK. Human chromosome 8-complemented scid cells, containing the human DNA-PK catalytic subunit, restored Ku phosphorylation. Likewise, radiation-induced RPA hyperphosphorylation was not completed in scid cells compared with control or chromosome 8-reconstituted cells. Thus, the inactivity of DNA-PK is likely responsible for the repair and recombination defects in scid cells.

Title

Delayed chromosomal instability in human T-lymphocyte clones exposed to ionizing radiation.

Source

International Journal of Radiation Biology. 68(3):245-55, 1995 Sep.

Abstract

Recent studies have demonstrated that cells which survive alpha-particle and X-ray exposure may show chromosomal instability, i.e. they continue to develop chromosomal aberrations at an increased frequency for many division cycles after the exposure. To characterize this delayed response, we carried out repeated karyotype analyses of X-irradiated T-lymphocytes during clonal expansion in vitro. Human peripheral blood lymphocytes were obtained from a healthy donor and exposed to 3-Gy X-irradiation. Cell survival, estimated by a cell cloning assay, was 5%. Non-irradiated, control cells were studied in parallel. Monoclonal cell lines were established using the T-cell cloning procedure. G-band karyotype analyses were carried out at several intervals during expansion of the clones for up to 2 months. The irradiated clones did not differ from the control clones with regard to growth rate or cytometric DNA profile.

Non-irradiated cell clones showed a normal karyotype, with < 10% of sporadic, non-clonal chromosome and chromatid breaks. In the irradiated clones, the karyotypes showed different (sub)clonal chromosome rearrangements, which developed successively during the cultivation time. In addition to these karyotypic abnormalities, > 20% of the cells in these

clones had sporadic, non-clonal chromosome aberrations, and there was a tendency of increasing frequency of such aberrations by length of cultivation. Thus, two types of radiation-induced chromosomal instability were observed; (sub)clonal karyotypic abnormalities and sporadic, non-clonal chromosome aberrations. The frequency and kinetics by which these alterations occur in the progeny of X-irradiated T-cells suggest that they arise through different pathways, and argue against their causation by mutation or persistent DNA damage.

Title

Trolox inhibits apoptosis in irradiated MOLT-4 lymphocytes.

Source

FASEB Journal. 9(13):1345-54, 1995 Oct.

Abstract

MOLT-4 cells, a human lymphocytic leukemia line, undergo apoptosis in response to a variety of stimuli, including exposure to ionizing radiation. Very little is known of the molecular mechanisms by which radiation induces apoptosis. Morphology changes and chromatin cleavage at internucleosomal sites accompany apoptosis in these cells. We found that trolox, a water-soluble derivative of vitamin E that penetrates biomembranes and protects mammalian cells from oxidative damage, blocks DNA fragmentation in irradiated MOLT-4 cells. Levels of DNA fragmentation in cells not treated with trolox were directly related to both radiation dose and time postirradiation. Preincubation of cells with trolox or incubation with trolox only during irradiation did not protect cells. A 4 h postirradiation incubation with trolox was sufficient to completely block fragmentation measured at 24 h, indicating the processes triggered by radiation to induce DNA fragmentation occur early after irradiation. Removal of cells from trolox earlier than 4 h resulted in progressively less inhibition. Trolox preserves the integrity of irradiated cells as judged by increased viability and thymidine incorporation. Radiation induces an uptake of extracellular Ca^{2+} into MOLT-4 cells that was blocked by a postirradiation incubation with trolox. These results suggest that membrane-associated oxidations triggered by radiation are responsible for radiation-induced apoptosis in MOLT-4 cells.

Source

Radiatsionnaia Biologiia, Radioecologiia. 35(3):391-404, 1995 May-Jun.

Abstract

It is shown that external as well as incorporated radiation inhibit the endocrine function of the thymus in the result of the direct and indirect effects. Postradiation deficiency of thymic hormones plays a significant role in pathogenesis of functional disorders in the immunity system. Immunocorrection with thymic agents is the most effective method when the mechanism of inhibition of thymic hormonal function are taken into account. [References: 126]

Title

Validation of chromosome painting. II. A detailed analysis of aberrations following high doses of ionizing radiation in vitro.

Source

International Journal of Radiation Biology. 67(1):19-28, 1995 Jan.

Abstract

Fluorescence in situ hybridization with chromosome-specific composite DNA probes ('chromosome painting') is useful for quantifying radiation-induced cytogenetic damage. Recently we showed that the frequency of aberrations observed with painting is similar to that seen with conventional cytogenetic methods, at least at doses of ≤ 2 Gy. Above this dose, however, the agreement was not as good. We describe here the results of additional work designed to clarify our earlier findings, and provide a detailed analysis of the type and frequency of aberrations induced in human peripheral lymphocytes following acute exposure to ^{137}Cs at doses of 0 (unexposed control), 1, 2, 3 and 4 Gy. The newly-developed nomenclature for chromosome aberrations detected by painting (Protocol for Aberration Identification and Nomenclature Terminology, 'PAINT') was used to classify all aberrations. Our results indicate that if the guidelines of the PAINT system are followed, chromosome painting can provide meaningful biodosimetry at high doses, and that the observation of complicated rearrangements not only does not interfere with dose estimation, but also the information provided by these exchanges can be easily broken down into the component aberrations and included in the dose estimate. We also show that the inequality between translocations and dicentrics that we previously observed can be explained by an excess of one class of translocated chromosomes, specifically those in which the centromere is from an unpainted chromosome. Translocated chromosomes in which the centromere is painted were found to occur at a frequency equal to dicentrics. These results should help clarify the use of painting for radiation biodosimetry by improving our understanding of the frequencies of various types of stable aberrations observed shortly after exposure. This will improve our ability to perform meaningful biodosimetry long after the frequencies of unstable aberrations have ceased to be informative.

Title

Application of a multiple fixation regimen to study the adaptive response to ionizing radiation in lymphocytes of two human donors.

Source

Mutation Research. 326(1):109-16, 1995 Jan.

Abstract

The majority of experiments studying the adaptive response using chromosomal aberrations have been performed with proliferating lymphocytes. It is known that lymphocytes have variable cell cycle transit times and it has been pointed out that in such cases aberration scores obtained from a single harvest are not very meaningful because cells harvested together in metaphase at any one time after irradiation were in different parts of the cell cycle at the time of irradiation. The scored sample will thus always contain a mixture of cells having different radiosensitivities and any variations of cell proliferation will influence the aberration score. In order to get a more representative aberration score a multiple fixation regimen was applied to lymphocytes of two human donors. Cells receiving the adapting + challenging and the challenging dose were fixed at three intervals after the challenge. In lymphocytes of donor 1 no adaptive response was seen at any fixation time in two experiments. In lymphocytes of donor 2, however, a reduction of aberration frequencies was seen, but at different fixation times in the two experiments. In a third experiment, no adaptive response was detected. It is concluded that the response observed at some fixation times in lymphocytes of donor 2 is rather a result of some phenomenon associated with variations of cell cycle kinetics than of induced radiation resistance.

Potential genotoxic risk related to simultaneous exposure to radionuclides and cytostatics.

Source

American Journal of Industrial Medicine. 27(6):871-6, 1995 Jun.

Abstract

The aim of the study was to evaluate the genotoxic risk to medical personnel concurrently exposed to ionizing radiation and antineoplastics, using changes in their lymphocyte cell genome as a bioindicator. The study comprised 12 female nurses employed in the nuclear medicine hospital department and an equal number of matched controls. For each examinee, both conventional structural chromosomal aberration analysis and sister chromatid exchange test (SCE) were carried out. According to Student's t-test, neither the incidence of structural chromosomal aberrations ($p > 0.6$) nor the mean SCE-frequency rate ($p > 0.3$) were significantly increased among the exposed subjects. Nevertheless, in those exposed, irreparable chromosomal damages and wide SCE-ranges were observed. Such findings suggest the possibility of genotoxic implications of concurrent occupational exposure to ionizing radiation and antineoplastic drugs.

Title

Increased induction of apoptosis in mononuclear cells of a glucose-6-phosphate dehydrogenase deficient patient.

Source

Journal of Molecular Medicine. 73(1):47-9, 1995 Jan.

Abstract

Glucose-6-phosphate dehydrogenase (G6PD) deficiency belongs to the most common human disorders of metabolism. In affected patients generation of free radicals causes life-threatening hemolytic crises, for example, after consumption of certain drugs and foods or after infections. Rather than erythrocytes we analyzed mononuclear white blood cells of a patient suffering from G6PD deficiency with respect to their ability to enter apoptosis after treatment with daunorubicin, ionizing radiation, or dexamethasone. The induction of apoptosis was increased in G6PD-deficient cells compared to cells from eight normal donors. In parallel, the glutathione content of mononuclear cells from the G6PD-deficient patient was significantly decreased. While in affected patients decreased life span of erythrocytes damaged by oxidative stress has long been recognized as the mechanism underlying hemolysis, peripheral leukocytes have not received similar attention. Induction of apoptosis is a relatively complex process that has been linked to cellular glutathione content. This is the

first report investigating G6PD deficiency and apoptosis.

Title

Influence of five methylsulphonyl PCB congeners on frequency of
micronucleated cells in cultured human lymphocytes by cytokinesis block
method.

Source

Fukuoka Igaku Zasshi - Fukuoka Acta Medica. 86(5):190-6, 1995 May.

Abstract

The lungs and blood of Yusho patients and healthy Japanese people have already been contaminated with methylsulphonyl polychlorinated biphenyls (MSF-PCBs) at relatively high concentration. Therefore, we should give due attention to their biological and toxicological effects to man. In this study, in order to mainly evaluate non-S-dependent genotoxicity of five MSF-PCB congeners, namely, 3-MSF-4, 5, 3', 4'-tetrachlorobiphenyl (TCB), 3-MSF-4, 5, 2', 3'-TCB, 3-MSF-2, 5, 2', 4', 5'-pentachlorobiphenyl (PenCB), 4-MSF-2, 5, 2', 3', 4'-PenCB and 4-MSF-2, 5, 2', 3', 5', 6'-hexachlorobiphenyl (HCB). We have examined their effects on the induction of micronucleated cells, which has been frequently used to estimate the dose of ionizing radiation and truly radiomimetic, non-S-dependent, clastogens, in cultured human lymphocytes in the absence or presence of 2, 3, 4, 7, 8-pentachlorodibenzofuran (PenCDF), 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) or 3, 4, 5, 3', 4'-pentachlorobiphenyl (Co-PenCB). The following results were obtained. 1) 4×10^{-5} M 7, 8-benzoflavone (ANF) significantly enhanced the frequency of micronucleated cells and all of the five MSF-PCB congeners failed to induce the formation of micronucleated cells at doses of 5.2 to 9.6 ppm, which were about 35,000 times higher than the concentrations in the lungs and adipose tissue of healthy Japanese people.(ABSTRACT TRUNCATED AT 250 WORDS)

Title

The in vivo inhibitory effect of ionizing radiation on Fc and C3 receptors on mouse granulocytes in bone marrow cells and in mouse and human monocytes in peripheral blood, and the radioprotective potential of human albumin.

Source

Archives of Medical Research. 26(2):163-8, 1995 Summer.

Abstract

Dose-dependent damage to Fc and C3 receptors on leukocytes by ionizing radiation was obtained with monocytes in peripheral blood leukocytes (M-PBL) as well as granulocytes in bone marrow cells (G-BMC) from total body irradiated mice. G-BMC from these mice took more than 4 months after irradiation to present normal levels of Fc and C3 receptors. Evidence is provided that albumin can protect Fc and C3 receptors from the damage of ionizing radiation in a dose-dependent way, and that this radioprotection can last for several days after albumin administration. In general, M-PBL from cervical cancer patients under radiotherapy maintained normal values of C3 receptors as compared to non-albumin-treated patients where an important decrease was found.

Title

Defective induction of stress-activated protein kinase activity in ataxia-telangiectasia cells exposed to ionizing radiation.

Source

Cancer Research. 55(15):3242-5, 1995 Aug 1.

Abstract

The activity of stress-activated protein (SAP) kinase is stimulated by diverse agents such as tumor necrosis factor, UV light, and protein synthesis inhibitors. The present study demonstrates that ionizing radiation (IR) exposure is also associated with the induction of SAP kinase activity. Cells derived from patients with ataxia-telangiectasia (A-T) are characterized by hypersensitivity to IR. In this study, we demonstrate that IR-induced activation of SAP kinase is defective in A-T cells. In contrast, exposure of A-T cells to UV light or anisomycin results in the induction of SAP kinase activity. These findings indicate that IR-induced signals involved in SAP kinase activation are defective in A-T cells.

Correction of chromosomal instability and sensitivity to diverse mutagens by a cloned cDNA of the XRCC3 DNA repair gene.

Source

Proceedings of the National Academy of Sciences of the United States of

America. 92(14):6354-8, 1995 Jul 3.

Abstract

The mutagen-sensitive CHO line irs1SF was previously isolated on the basis of hypersensitivity to ionizing radiation and was found to be chromosomally unstable as well as cross-sensitive to diverse kinds of DNA-damaging agents. The analysis of somatic cell hybrids formed between irs1SF and human lymphocytes implicated a human gene (defined as XRCC3; x-ray repair cross-complementing), which partially restored mitomycin C resistance to the mutant. A functional cDNA that confers mitomycin C resistance was transferred to irs1SF cells by transforming them with an expression cDNA library and obtaining primary and secondary transformants. Functional cDNA clones were recovered from a cosmid library prepared from a secondary transformant. Transformants also showed partial correction of sensitivity to cisplatin and gamma-rays, efficient correction of chromosomal instability, and substantially improved plating efficiency and growth rate. The XRCC3 cDNA insert is approximately 2.5 kb and detects an approximately 3.0-kb mRNA on Northern blots. The cDNA was mapped by fluorescence in situ hybridization to human chromosome 14q32.3, which was consistent with the chromosome concordance data of two independent hybrid clone panels.

Title

Mild hyperthermia can induce adaptation to cytogenetic damage caused by subsequent X irradiation.

Source

Radiation Research. 143(1):26-33, 1995 Jul.

Abstract

Many low-level environmental agents are able to induce an increased resistance to subsequent mutagenic effects induced by ionizing radiation. In this paper, an induced cytogenetic adaptation to radiation in human lymphocytes was studied with mild hyperthermia as the adaptive treatment and compared with that induced by low-dose radiation. We found that this adaptation could be induced not only in PHA-stimulated human lymphocytes (at 14, 38 and 42 h after addition of PHA), but also in unstimulated G0-phase cells (before addition of PHA) by mild hyperthermia (41 degrees C for 1 h) as well as 50 mGy X rays. When the two adaptive treatments were combined, no additive effects on the magnitude of the adaptation induced were observed, suggesting that low-dose radiation and hyperthermia may share one mechanism of induction of adaptation to cytogenetic damage. Some mechanisms which may be involved in the induction of adaptation to cytogenetic damage by low-dose radiation are discussed and compared with the effects of mild hyperthermia in inducing thermotolerance and radioresistance.

Title

Relationships between G1 arrest and stability of the p53 and p21Cip1/Waf1 proteins following gamma-irradiation of human lymphoma cells.

Source

Cancer Research. 55(11):2387-93, 1995 Jun 1.

Abstract

We investigated temporal relationships between ionizing radiation-induced G1 arrest and induction of the p53-regulated genes GADD45, CIP1/WAF1, and MDM2 in a series of Burkitt's lymphoma and lymphoblastoid cell lines that differed in p53 gene status. Emphasis was placed on characterization of the EW36 cell line, which despite expressing wild-type p53 genes, is defective in G1 arrest following gamma-irradiation (P. M. O'Connor et al., Cancer Res., 53: 4776-4780, 1993). Induction of CIP1/WAF1, GADD45, and to a lesser extent MDM2 mRNA was observed in all wild-type p53 lines that arrested in G1. Cell lines that contained only mutant p53 genes or were heterozygous for p53 mutations failed to induce appreciable levels of these p53-regulated transcripts and did not arrest in G1. G1 arrest in the wild-type p53 cell line WMN was more prolonged than elevation of CIP1/WAF1, GADD45, or MDM2 transcripts, suggesting that G1 arrest duration must be dependent upon stability of these newly synthesized proteins. In agreement, we found that p21Cip1/Waf1, a potent inhibitor of G1-S phase cyclin-dependent kinases, was maintained at elevated levels throughout the period that WMN cells remained arrested in G1. EW36 cells exhibited normal induction of CIP1/WAF1, GADD45, and MDM2 mRNA following gamma-irradiation, suggesting that the defect in G1 arrest must reside downstream of p53 transactivation. Investigations into the stability of p53 and p21Cip1/Waf1 revealed that EW36 cells failed to maintain elevated levels of these proteins following irradiation. p53 levels decreased within 4 h of irradiation, and p21Cip1/Waf1 levels decreased shortly after the normal decline of CIP1/WAF1 mRNA levels. Degradation of p21Cip1/Waf1 coincided with the escape of EW36 cells from G1 arrest. Our studies suggest that p21Cip1/Waf1 stability may determine G1 arrest duration and that premature degradation of this protein could provide an alternative route to subversion of the G1 checkpoint in cancer cells.

Title

A role for mismatch repair in production of chromosome aberrations by methylating agents in human cells.

Source

Mutation Research. 346(4):231-45, 1995 Apr.

Abstract

We have shown previously that certain alkylation products, or alkylation derived lesions, which induce chromosome aberrations (abs) persist for at least two cell cycles in Chinese hamster ovary cells. The increase in abs in the second cycle after treatment contrasts with the classical observation of reduction in ab yield with successive mitoses following ionizing radiation. Here we present evidence that processing of lesions by mismatch repair is a mechanism for ab induction by methylating agents. Our previous studies implicated O6-methylguanine (O6MeG) as an important lesion in induction of abs, particularly in the second cell cycle after treatment. In the absence of repair of O6MeG by alkylguanine DNA alkyltransferase (AGT), new abs were induced in the second cycle after treatment with e.g. methylnitronitrosoguanidine (MNNG) and methylnitrosourea (MNU). Thus, we hypothesized that abs were produced not by O6MeG or its repair in the first S phase, but by subsequent processing of the lesions. We suggested that after replication proceeded past the O6MeG lesion in the first S phase, inserting an incorrect base on the newly synthesized strand, recognition and repair by mismatch repair in the second S phase led to a chromosome ab. Here we used MT1 cells, a human lymphoblastoid cell line that has a defect in strand-specific mismatch repair. MT1 cells are alkylation tolerant and have a mutator phenotype, compared with their parent line, TK6; both MT1 and TK6 cells lack AGT so do not remove the methyl group from O6MeG. While the initial levels of abs at the first metaphase were similar in MT1 and TK6 cells, ab levels in MT1 cells were greatly reduced in the second and third cell cycles following treatment with MNNG, dimethylnitrosamine and MNU, in contrast with the parent TK6 cells, which had more abs in the second cell cycle than in the first. This supports the hypothesis that repair of mismatched base pairs involving O6MeG is one mechanism for induction of chromosome abs. In contrast to the difference in response to methylating agents between TK6 cells and mismatch repair-deficient MT1 cells, the profile of ab induction by an ethylating agent, ethylnitrosourea, was similar in MT1 cells to those for TK6 cells and CHO cells.

Title

A modified immunochemical assay for the fast detection of DNA damage in human white blood cells.

Source

Mutation Research. 334(3):347-56, 1995 Jun.

Abstract

An immunochemical assay to detect damage in DNA has been modified to a so-called sandwich ELISA. With this assay DNA damages can be detected that give rise to a certain level of single-strandedness in DNA of white blood

cells during partial unwinding of cellular DNA under alkaline conditions. The modified method includes the following steps: incubation of alkali-treated whole blood in the wells of microtiter plates precoated with antibody directed against single-stranded DNA (ssDNA), which results in selective binding of ssDNA, and the subsequent detection of bound ssDNA by incubation with anti-ssDNA antibody alkaline phosphatase conjugate. With this method the amount of damage induced by ionizing radiation in DNA in cells of human blood can be detected within 1 h, after doses as low as 0.2 Gy. The precoating of microtiter plates with anti-ssDNA antibody enables the detection of ssDNA fragments directly in alkali-treated blood samples, isolation of the nucleated cells from the blood is not necessary. Because the DNA is released somewhat faster from lymphocytes than from granulocytes upon alkali treatment, it even appeared possible to discriminate between the effect of the radiation on these cell types in the same blood sample. The method is also applicable to other cell types that can be obtained in suspension.

Title

Absence of radiation-induced G1 arrest in two closely related human lymphoblast cell lines that differ in p53 status.

Source

Journal of Biological Chemistry. 270(19):11033-6, 1995 May 12.

Abstract

In order to examine more precisely the role of p53 in the activation of the G1/S checkpoint by ionizing radiation, we examined two human lymphoblast cell lines derived from the same donor. The TK6 line had a doubling time of 12.2 h and expressed wild type p53, while the WTK1 line had a doubling time of 12.7 h and expressed mutant p53. The two lines differ significantly in their susceptibility to radiation-induced cell killing and apoptosis. Cells were examined by flow cytometry at regular intervals from 0 to 12 h after irradiation with two different doses designed to yield equivalent survival levels in both cell lines. In some experiments, cells were incubated with colcemid to block them in the first postirradiation mitosis and prevent contamination of the flow cytometric profiles with second cycle cells. There was no significant difference between the two cell lines in the progression of irradiated cells out of G1 and into the S and G2 phases of the cell cycle. In particular, there was no evidence for a prolonged arrest in G1 in the TK6 cell line expressing wild type p53. Furthermore, expression of the p53 downstream genes WAF1/CIP1 and RB appeared normal in TK6 cells. These results suggest that factors other than those in the p53 signal transduction pathway alone may be required to activate the G1/S checkpoint in irradiated human cells and that apoptosis and G1 arrest may utilize different pathways.

Title

Chromosomal damage in workers occupationally exposed to chronic low level ionizing radiation.

Source

Toxicology Letters. 76(2):113-7, 1995 Mar.

Abstract

Chromosomal aberrations were evaluated in cultures of peripheral lymphocytes from subjects working in diagnostic X-ray and nuclear medicine areas, exposed to electromagnetic ionizing radiation and particulate ionizing emissions, respectively. A 4-fold increase in the level of chromosomal aberrations was found between the exposed and control groups without qualitative or quantitative cytogenetic differences between X-rays and nuclear medicine-exposed workers. Results are discussed in view of the early damage detection from chronic exposures particularly related to biological controls, hygienic improvements and overwork in a developing country.

Title

The scid factor on human chromosome 8 restores V(D)J recombination in addition to double-strand break repair.

Source

Cancer Research. 55(8):1774-9, 1995 Apr 15.

Abstract

The murine severe combined immune deficiency mutation (scid) is characterized by a lack of B- and T-lymphoid cells due to a defect in lymphoid V(D)J recombination. Moreover, defective rejoining of DNA double-strand breaks (dsb) in scid cells also results in a marked increase in sensitivity to ionizing radiation. Recently, the putative human homologue of the murine scid gene locus, HYRC1, was assigned to human chromosome 8q11, based on the radiation sensitivity of scid cells as compared to scid:human cell hybrids carrying portions of human chromosome 8. Given the precedent (e.g., ataxia-telangiectasia) for genes other than the affected one being able to complement radiation defects, we were interested in determining if the V(D)J recombination defect was also corrected by the HYRC1 locus. The V(D)J recombination analysis using extrachromosomal DNA substrates in control scid cells (SC3VA2) versus complemented cells (RD13B2) indicates that the radiation sensitivity-complemented cells (RD13B2) are also fully complemented for the V(D)J recombination reaction, whereas the control (uncomplemented)

cells (SC3VA2) fail to carry out V(D)J recombination normally. Slightly over 60% of the radiation-induced dsb are rejoined even in scid cells, and this alternative pathway is temperature sensitive. Only the remaining 30-35% of dsb require the introduction of the HYRC1 locus, and this pathway is not temperature sensitive. This merely partial contribution of the scid factor to the repair process suggests the presence of another pathway of dsb repair. Our results indicate that the HYRC1 locus, assigned to human chromosome 8q11, encodes the scid factor, which is involved in all V(D)J recombination coding joint formation and in 30-35% of dsb repair by the temperature-resistant pathway.

Title

Protection from radiation-induced chromosomal aberrations by the nitroxide Tempol.

Source

Cancer. 75(9):2323-7, 1995 May 1.

Abstract

BACKGROUND. The nitroxide Tempol (4-hydroxy-2,2,6,6-tetramethylpiperidine-1-oxyl) is a stable, free radical that exhibits protection from ionizing radiation damage and from oxidative stress mediated through exposure of cells to superoxide or hydrogen peroxide. Radiation protection has been observed in both in vivo and in vitro models. To understand the mechanism of Tempol-mediated radioprotection better, the production of radiation-induced chromosome aberrations was evaluated. This study analyzed Tempol-mediated radioprotection of human peripheral blood lymphocytes (PBLs). **METHODS.** Peripheral blood lymphocytes were exposed to control (0mM), 10 mM (Tp10), and 50 mM (Tp50) concentrations of Tempol for 20 minutes before irradiation with 0, 150, 300, and 450 cGy. One quarter ml whole blood was cultured in F12 medium and phytohemagglutinin at 37 degrees C for 49, 54, 59, and 64 hours. Colcemide was added to each sample for the last 5 hours before harvest. Cells were harvested, treated with hypotonic solution, and fixed before dropping on cold clean slides. Mitotic indices and frequency of dicentric, ring, and triradial chromosomal aberrations were determined at 1000x magnification for each treatment group at each collection point. **RESULTS.** Treatment of cells with Tempol alone did not induce the chromosomal aberration frequency above that for unirradiated controls. Radiation dose response curves for total chromosome aberration production revealed radioprotection for Tempol treatment for both 10 and 50 mM exposures. Tempol protection factors (assessed at 0.2 aberrations/cell level) for Tp 10 and Tp 50 were 2.2 and 2.8, respectively. **CONCLUSIONS.** Tempol protects against radiation-induced chromosome aberrations in human PBLs. This finding is consistent with and lends support to previous studies in which Tempol was reported to enhance cell survival and reduce

radiation-induced DNA double strand breaks.

Title

Flow cytometric analysis of micronuclei in the CD2+/- subpopulation of
human lymphocytes enriched by magnetic separation.

Source

International Journal of Radiation Biology. 67(2):193-202, 1995 Feb.

Abstract

An improved flow cytometric method for the scoring of micronuclei in human lymphocytes irradiated in vitro is presented. Because, especially in cultivated human lymphocytes, unspecific DNA-containing debris from dying cells can influence the measured frequency of micronuclei, a preselection of CD2 + population was performed before preparation of the suspension of micronuclei and nuclei. Magnetic separation using anti-CD2 antibody-conjugated magnetic beads were used for this purpose. The results obtained by this improved flow cytometric technique were compared with results obtained by microscopic scoring using the CB technique. No correlation was found when the individual values in unirradiated controls were compared, due mainly to the presence of DNA-containing particles from fragmented cell nuclei and other unspecific debris. The averaged data from nine dose-effect curves simultaneously analysed by both techniques showed a linear-quadratic dose dependence with alpha and beta's that were similar for flow cytometry and for microscopic scoring. Only the constant term was higher for the flow cytometric results. A correlation between both techniques applied to individual data at doses > 0.2 Gy could also be demonstrated. It is concluded that a dose estimation of man exposed to low doses of ionizing radiation can at present not be improved by the flow cytometric technique.

Title

Mutational spectrum of X-ray induced TK- human cell mutants.

Source

Carcinogenesis. 16(2):267-75, 1995 Feb.

Abstract

Mutations induced by ionizing radiation have historically elicited significant public concern. However, only a limited database of ionizing radiation-induced point mutations is available, particularly at endogenous human cell loci. Here, we report the mutational spectrum for 184 X-ray

induced TK- mutants derived from TK6 human lymphoblasts. This report represents the first large scale utilization of the tk locus for investigation of mutational specificity at the DNA sequence level. Rapid, single nucleotide sequencing assays at frameshift polymorphism sites in tk exons 4 and 7 were used to partition TK- mutants into two groups: 126 were attributed to either partial gene deletion or to loss of heterozygosity, and DNA sequence alterations were identified for 51. X-ray-induced point mutations included all classes of transitions and transversions, tandem base substitutions, frameshifts, small deletions and a small duplication. The distribution within tk was characterized by clustering at some sites. Twelve TK- point mutations, including five entirely within the coding sequence in exons 3 and 4, resulted in aberrant splicing of the tk transcript. The spectrum of X-ray-induced point mutations was found to be highly reproducible when TK- mutations were compared with HPRT- mutations in TK6. A statistically significant decrease in transitions ($P = 0.04$) was observed in the combined data set as compared to the spontaneous background. These findings suggest a reproducible pattern which may be utilized in recognizing radiation-induced mutations at other loci of interest.

Title

Chromosome aberrations produced by radiation: the relationship between excess acentric fragments and dicentrics.

Source

Radiation Research. 141(2):136-52, 1995 Feb.

Abstract

Most chromosome aberrations produced by ionizing radiation develop from DNA double-strand breaks (DSBs). Published data on the yield and variance of excess acentric fragments after in vitro irradiation of human lymphocytes were compared with corresponding data on dicentrics. At low LET the number of excess acentric fragments is about 60% of the number of dicentrics, independent of dose and perhaps of dose rate, suggesting that dicentrics and excess acentric fragments arise from similar kinetics rather than from fundamentally different reactions. Only a weak dependence of the ratio on LET is observed. These results are quantified using generalizations of models for pairwise DSB interactions suggested by Brewen and Brock based on data for marsupial cells. By allowing singly incomplete and some "doubly incomplete" exchanges, the models can also account for the experimental observation that the dispersion for excess acentric fragments, a measure of cell-to-cell variance, is systematically larger than the dispersion for dicentrics. Numerical estimates of an incompleteness parameter are derived.

Title

Defect in radiation signal transduction in ataxia-telangiectasia.

Source

International Journal of Radiation Biology. 66(6 Suppl):S151-6, 1994 Dec.

Abstract

Exposure of mammalian cells to ionizing radiation causes a delay in progression through the cycle at several checkpoints. Cells from patients with ataxia-telangiectasia (A-T) ignore these checkpoint controls postirradiation. The tumour suppressor gene product p53 plays a key role at the G1/S checkpoint preventing the progression of cells into S phase. The induction of p53 by radiation is reduced and/or delayed in A-T cells, which appears to account for the failure of delay at the G1/S checkpoint. We have investigated further this defect in radiation signal transduction in A-T. While the p53 response was defective after radiation, agents that interfered with cell cycle progression such as mimosine, aphidicolin and deprivation of serum led to a normal p53 response in A-T cells. None of these agents caused breaks in DNA, as determined by pulse-field gel electrophoresis, in order to elicit the response. Since this pathway is mediated by protein kinases, we investigated the activity of several of these enzymes in control and A-T cells. Ca²⁺-dependent and -independent protein kinase C activities were increased by radiation to the same extent in the two cell types, a variety of serine/threonine protein kinase activities were approximately the same and anti-tyrosine antibodies failed to reveal any differences in protein phosphorylation between A-T and control cells. It is not evident what is the nature of the defect in signal transduction in A-T cells. However, it is clear that the p53 response is normal in these cells after exposure to some agents and it is mediated through protein kinase C or another serine/threonine kinase.

Title

Frequent involvement of visible chromosomal deletion in X-ray-induced mutants at the HLA-A locus in human T-lymphocytes.

Source

Mutation Research. 309(1):63-72, 1994 Aug 1.

Abstract

Mutant T-lymphocytes at the HLA-A locus were isolated using a recently developed flow-cytometric assay either immediately after drawing blood (in vivo mutants) or after X-irradiation in vitro. Mutants were subsequently

propagated clonally for cytogenetic and molecular analyses. Among the 38 in vivo mutants, none contained an abnormal chromosome 6 on which the HLA-A locus resides (6p21.3). In contrast, mutants recovered after in vitro irradiation frequently carried abnormalities in the short arm of chromosome 6: 11/19 and 5/5 independent mutants for the 1-Gy and 2-Gy groups, respectively. Characteristically, the majority of the aberrations were deletions, commonly involving chromosome 6p21-p23. Because chromosomal deletions involving the selected gene are rare among radiation-induced mutants at the hypoxanthine phosphoribosyltransferase (chromosome X) and thymidine kinase (chromosome 17) loci, the HLA-A locus can be considered as highly prone to chromosomal deletions after radiation exposure. It is generally believed that ionizing radiation randomly breaks DNA, and the higher frequency of chromosomal deletions at the HLA-A locus is unlikely to be due to preferential induction but more likely to the better survivability of the deletion-bearing mutants. Consequently, the results suggest that the human genome is quite heterogeneous with regard to the survivability of cells bearing a chromosomal deletion including different loci.

Title

Lack of chromosomal aberration and micronucleus induction in human lymphocytes exposed to pulsed magnetic fields.

Source

Mutation Research. 306(2):129-33, 1994 Apr 15.

Abstract

We exposed human peripheral blood lymphocyte cultures to 50 Hz pulsed magnetic fields (PMFs) in order to evaluate a possible genotoxic effect of such non-ionizing radiation. The genotoxic effect was evaluated in terms of both micronucleus (MN) induction and classical chromosomal aberrations (CA); the mitotic index (MI) was also calculated. Khalil and Qassem (1991) found chromosomal and chromatid breaks and mitotic delay in human lymphocytes exposed for 24, 48 and 72 h to a field with characteristics similar to those used in our laboratory. These data are in contrast with our results previously reported in terms of MN induction using the cytokinesis block method (Scarfi et al., 1991). In this study lymphocytes from five healthy human donors were examined with the above mentioned tests. No genotoxic effects and increased MI were found in exposed samples compared to the control ones, in agreement with our previous results.

Title

Detection and characterization of apoptotic peripheral blood lymphocytes in human immunodeficiency virus infection and cancer chemotherapy by a novel flow immunocytometric method.

Source

Blood. 83(5):1268-77, 1994 Mar 1.

Abstract

We have developed a quantitative and sensitive flow cytometric method for the detection of human apoptotic lymphocytes that, unlike previously described assays, allows their identification in mixed populations of peripheral blood leukocytes as well as their immunophenotyping. Apoptotic lymphocytes are identified on the basis of peculiar light scatter changes, reflecting their smaller size and their modified nucleus/cytoplasm organization, and of the decreased expression of surface CD45 molecules. Based on these criteria, apoptotic lymphocytes generated by exposure to ionizing radiation can be easily distinguished from viable cells and from necrotic lymphocytes generated by treatment with antibody and complement. Using this assay, we reappraised the phenomenon of the in vitro apoptosis of lymphocytes from patients with human immunodeficiency virus (HIV) infection. Lymphocytes from HIV patients, unlike those from normal HIV-negative subjects, undergo apoptosis upon simple in vitro culture. We found that the percentages of lymphocytes undergoing apoptosis were significantly higher in patients with low CD4 cell counts ($< 400/\mu\text{mL}$) than in patients at earlier stages (> 400 CD4 cells/ μmL). However, phenotypic analysis disclosed that apoptotic lymphocytes generated in these cultures were mostly CD8⁺ T cells and CD19⁺ B cells. Thus, in contrast to what has been previously suggested, the phenomenon of in vitro lymphocyte apoptosis might not be pathogenetically related to the depletion of CD4⁺ T cells in acquired immunodeficiency syndrome. Nevertheless, it might represent an useful marker of disease progression. Our assay allows the analysis of unfractionated peripheral blood leukocytes and thus the identification of apoptotic lymphocytes circulating in vivo. Apoptotic lymphocytes could indeed be detected in the circulation of a patient with cancer shortly after high-dose cytotoxic chemotherapy. By contrast, no apoptotic lymphocytes could be detected in vivo in patients with early or advanced HIV infection.

Title

Glycolaldehyde causes DNA-protein crosslinks: a new aspect of ethylene oxide genotoxicity.

Source

Mutation Research. 304(2):229-34, 1994 Jan 16.

Abstract

After in vitro incubation of human peripheral mononuclear blood cells with glycolaldehyde (a putative metabolite of ethylene oxide) for 2 h at 37

degrees C, a dose-dependent increase in DNA crosslinks was observed in a dose range between 1 and 10 mM using the alkaline filter elution technique. The elution rate of mononuclear blood cells after treatment with ionizing radiation (600 cGy) was reduced more than 5-fold if cells were incubated with 10 mM glycolaldehyde for 2 h. After treatment with proteinase K DNA crosslinks were no longer detected in cells incubated with glycolaldehyde. Therefore the crosslinks produced by glycolaldehyde could clearly be identified as DNA-protein crosslinks. Additionally glycolaldehyde induced DNA single-strand breaks in a dose range between 1 and 10 mM. The elution rate of mononuclear blood cells was increased about 18-fold if cells were incubated with 5 mM glycolaldehyde for 2 h using an elution procedure with proteinase K. In vitro incubation of mononuclear cells with ethylene oxide for 2 h at 37 degrees resulted in a dose-dependent increase in DNA single-strand breaks between 0.5 and 10 mM ethylene oxide. Moreover, a time-dependent increase in DNA single-strand breaks after incubation with 1.5 mM ethylene oxide was observed with an increased number of single-strand breaks already detectable after 15 min and a maximum level which was detected after 2 h of incubation. However, no DNA-DNA or DNA-protein crosslinks could be detected although a wide concentration range and many different incubation times were tested. Therefore DNA crosslinks, for which evidence was found in mononuclear blood cells of humans occupationally exposed to ethylene oxide, are possibly generated by glycolaldehyde, a putative intermediate in the metabolism of ethylene oxide to glycolic acid.

Title

Modification of radiation-induced apoptosis in radiation- or hyperthermia-adapted human lymphocytes.

Source

Biochemistry & Cell Biology. 72(11-12):475-82, 1994 Nov-Dec.

Abstract

We have investigated the influence of the cellular adaptive response to ionizing radiation on radiation-induced apoptosis in human cells. The adaptive response is believed to be a protective mechanism that confers resistance to the detrimental effects of ionizing radiation and that can be induced by different agents, including hyperthermia and radiation. We have used fluorescence analysis of DNA unwinding (FADU) to assay the induction of apoptosis in human peripheral blood lymphocytes by ionizing radiation. Using the FADU assay, we have observed the initial radiation-induced DNA damage, its subsequent disappearance due to enzymatic repair, and its time- and dose-dependent reappearance. We believe this reappearance of DNA damage to be indicative of the DNA fragmentation event associated with apoptosis. This interpretation has been supported at the individual cell level using an in situ terminal

deoxynucleotidyl transferase (TDT) assay (Apoptag, Oncor Inc.), which detects the 3'-hydroxyl ends of fragmented DNA, and by fluorescence analysis of nuclear morphology in Hoechst 33258 stained cells. Pretreatment of cells with low-dose gamma-radiation (0.1 Gy) or mild hyperthermia (40 degrees C for 30 min) altered the extent of radiation-induced (3 Gy) apoptosis. Both pretreatments sensitized lymphocytes to become apoptotic after the 3-Gy radiation exposure. This sensitization may represent an adaptive response mechanism that reduces the risk that genetically damaged cells will proliferate. The ability to modify the probability of radiation-induced apoptosis may lower the cancer risk from a radiation exposure.

[The significance of the hypoxic factor in adaptation to the action of ionizing radiation as a result of the accident at the Chernobyl Atomic Electric Power Station]. [Ukrainian]

Source

Vrachebnoe Delo. (9-12):46-50, 1994 Sep-Dec.

Abstract

Data are presented from cytochemical study of the neutrophil myeloperoxidase oxygen dependent enzymes and lymphocyte succinate dehydrogenase in the peripheral blood of 2169 persons subjected to follow-ups of many kinds, at year 7 and 8 after the Chernobyl accident. By comparison with early time periods, the process of normalization of the measured values has been found to be the case, with SDG returning to normal earlier than MPO. There was an increase in the number of individuals with reduced MPO activity and stable percentage of those demonstrating increased SDG activity (30-42% versus 12%). Significance of the adaptation process in the time course of changes of the values measured is discussed along with role of hypoxic factor in adaptation to the ionizing irradiation exposure after the Chernobyl accident.

[Change in functional and metabolic activity of leukocytes and content of serum immunoglobulins of donor blood exposed to gamma radiation].
[Russian]

Source

Gematologiya i Transfuziologiya. 39(4):29-32, 1994 Jul-Aug.

Abstract

Changes in functional-metabolic activity of leukocytes and in donor serum immunoglobulin level in exposure to gamma radiation. B.S. Nagoev. Kabardin-Balkar University, Nalchik. The study of 40 samples of blood after 1-4 days of storage revealed a moderate significant reduction in concentrations of cation protein, in myeloperoxidase activity. In exposure to gamma radiation, there appeared dose- and intensity-related shifts in the blood elements morphology, inhibition of myeloperoxidase, in the content of leukocyte cation protein, serum immunoglobulins. These alterations in white blood morphological picture, inhibition of functional-metabolic activity of leukocytes and immunoglobulin unbalance during gamma radiation of isolated blood explain depression of immunobiological characteristics of the body in extreme conditions, particularly, the lack of antibacterial defense as a result of ionizing radiation.

Title

Scoring of radiation-induced micronuclei in cytokinesis-blocked human lymphocytes by automated image analysis.

Source

Cytometry. 17(2):119-27, 1994 Oct 1.

Abstract

The micronucleus assay in human lymphocytes is, at present, frequently used to assess chromosomal damage caused by ionizing radiation or mutagens. Manual scoring of micronuclei (MN) by trained personnel is very time-consuming, tiring work, and the results depend on subjective interpretation of scoring criteria. More objective scoring can be accomplished only if the test can be automated. Furthermore, an automated system allows scoring of large numbers of cells, thereby increasing the statistical significance of the results. This is of special importance for screening programs for low doses of chromosome-damaging agents. In this paper, the first results of our effort to automate the micronucleus assay with an image-analysis system are represented. The method we used is described in detail, and the results are compared to those of other groups. Our system is able to detect 88% of the binucleated lymphocytes on

the slides. The procedure consists of a fully automated localization of binucleated cells and counting of the MN within these cells, followed by a simple and fast manual operation in which the false positives are removed. Preliminary measurements for blood samples irradiated with a dose of 1 Gy X-rays indicate that the automated system can find 89% +/- 12% of the micronuclei within the binucleated cells compared to a manual screening.

[The immune system indices of hypertension patients exposed to ionizing radiation]. [Russian]

Source

Vrachebnoe Delo. (5-6):97-9, 1994 May-Jun.

Abstract

We studied immunologic status in patients with stage II hypertensive disease (HD): there were 92 Kievans and 46 subjects living in the area with excessive radiation within a 30-km radius of the Chernobyl Nuclear Power Plant; control group comprised 20 apparently healthy men (donors of the city station of blood transfusion). In HD patients the T-lymphocyte count was found to be reduced as was the content of T-suppressors and T-helpers, the activity of the B-immune system tending to be on the increase. Suppression of the T-lymphocyte suppressive function and elevation of the immunoglobulin G content result in an accelerated formation of circulating immune complexes, this indicating evolution of disturbances in immune complexes and an influence being exerted on the development of vascular affections and progression of atherosclerosis being promoted in these patients. Changes in the immune system tended to be more pronounced in st. II HB patients residing in the area with abnormal radiation than they were in the same category of patients--inhabitants of Kiev--this being supposedly a reason for disease progression in them.

Adaptive response to ionizing radiation in normal and aneuploid human lymphocytes.

Source

Folia Biologica. 40(3):119-23, 1994.

Abstract

The ability to induce an adaptive response by low doses of gamma rays was studied in normal and trisomic lymphocytes (47, XX or XY, +21). The results indicate the presence of an adaptive response in lymphocytes of 3 normal donors, but in lymphocytes of 5 donors with trisomy 21 no

significant adaptive response after irradiation with a low dose of gamma rays was found. There was similar chromosomal radiosensitivity in normal and trisomic lymphocytes (47, XX or XY, +21) irradiated with 1.50 Gy at the 48th hour after stimulation.

[Detection of heterozygotes for ataxia telangiectasia using sensitivity to ionizing radiation]. [Spanish]

Source

Revista Alergia Mexico. 41(4):98-102, 1994 Jul-Aug.

Abstract

Recent research have demonstrated that homozygotic and heterozygotic patients with ataxia telangiectasia (AT) show chromosomal rupture. Taking in consideration this characteristic, a study was designed, inducing chromosomal breaks in granulocytes from patients with AT, and heterozygotic carriers of AT compared with a group of healthy individuals. The number of chromosomic ruptures induced by 14 doses of radiation at 125 KV and 125 mA, was measured in all of them. Results suggest significant differences in the number of chromosomal structural alterations induced by radiation in granulocytes from heterozygotic carriers of AT, similar to structural alterations in lymphocytes from patients with AT. It is demonstrated that these alterations occur preferentially in one group C chromosome, both in homozygotic and heterozygotic patients with AT.

Title

Radiation damage to the erythrocyte membrane: the effects of medium and cell concentrations.

Source

Free Radical Research. 21(3):135-46, 1994 Sep.

Abstract

Human erythrocytes suspended in plasma, or in phosphate buffered saline (PBS), were exposed to ionizing radiation. Potassium leakage from irradiated erythrocytes is significantly higher in PBS than in plasma. The potassium leakage decreases when PBS is gradually replaced by plasma. These findings suggest that some of the plasma constituents have radioprotective properties. The potassium leakage per cell is independent of the hematocrit, Hct. The potassium leakage is attributed to the

formation of radiation defects in the membrane. Analysis of the effect of radiation dose, plasma and cell concentrations on the product of the number and surface area of the radiation defects indicates that the radiation damage is mainly due to the direct formation of free radicals in the cell membrane. The radioprotective effect of plasma is attributed to surface reactions of these free radicals with plasma constituents adsorbed on the membrane.

Title

Ionizing radiation increases endothelial and epithelial cell production of influenza virus and leukocyte adherence.

Source

Journal of Immunology. 153(11):5222-9, 1994 Dec 1.

Abstract

To characterize the effect of ^{60}Co gamma radiation on cell-cell and pathogen-cell interactions, the adherence of undifferentiated HL-60 cells to HUVEC monolayers was tested in the absence and presence of LPS or influenza virus type A. Basal HL-60 cell adherence to uninfected HUVEC monolayers ($3.0 \pm 1.6\%$, $n = 30$) was not altered when HUVECs were exposed to 1- to 10-Gy gamma irradiation 4 to 72 h before the adhesion assay. LPS treatment of HUVEC monolayers (0.5 microgram/ml, 4 h) produced a 6.9-fold increase in adherence that was not altered by previous irradiation. However, when HUVEC monolayers were subjected to 1-10 Gy 41 h before influenza virus infection (10^6 pfu/ml) for 7 h, virus-induced adherence was enhanced in a dose-dependent manner. Increased virus hemagglutinin (HA) protein expression mediated the radiation-induced adherence for the following reasons: 1) HA Ag increases paralleled increases in leukocyte adherence. 2) Northern blot analysis demonstrated a time-dependent increase in mRNA HA levels. 3) Anti-HA blocked HL-60 cell adherence to irradiated and virus-infected HUVEC monolayers. These changes were associated with an increased virus titer yield and virus-induced HUVEC killing. In contrast, cytotoxicity produced by vesicular stomatitis virus, which unlike influenza virus replicates cytoplasmically, was not altered by radiation in HUVECs. In related studies, the canine kidney epithelial (MDCK) cell line showed a similar increased influenza virus production after gamma radiation, indicating that the radiation-induced increase in production of influenza virus is not cell-specific and probably involves a nuclear mechanism.

Title

Ionizing radiation induces apoptotic cell death in human TcR-gamma/delta+ T and natural killer cells without detectable p53 protein.

Source

European Journal of Immunology. 24(11):2914-7, 1994 Nov.

Abstract

The p53 tumor suppressor gene has been shown to be involved in programmed cell death, apoptosis, in murine immature thymocytes after treatment with ionizing radiation. Ionizing radiation also induces apoptosis in peripheral mature lymphocytes. In this work, we investigated the p53 participation in radiation-induced apoptosis in human peripheral blood lymphocytes (PBL) subpopulations. Exposure to gamma-irradiation resulted in an appreciable induction of apoptotic cell death in TcR-alpha/beta+ (CD4+ and CD8+) T cells, TcR-gamma/delta+ T cells, B cells and natural killer (NK) cells, as assessed by DNA fragmentation as well as the morphological characteristics. Importantly, it was found that there was a marked difference among PBL subpopulations as regards the induction of p53 protein by gamma-irradiation. Similar to previous observations for murine thymocytes, p53 induction in TcR-alpha/beta+ T cells and B cells after gamma-irradiation was evident by Western blot analysis. Radiation-induced apoptosis in TcR-alpha/beta+ T cells and B cells was efficiently inhibited by cycloheximide, indicating the requirement of de novo protein synthesis, including p53 protein, for radiation-induced apoptosis in both subpopulations. In marked contrast, no identifiable levels of p53 protein were induced in either TcR-gamma/delta+ T or NK cells after gamma-irradiation. In addition, it was demonstrated that radiation-induced cell death in TcR-gamma/delta+ T and NK cells could be prevented by interleukin-2, but not by cycloheximide. These results imply that radiation-induced lymphocytic apoptosis can be mediated by p53-dependent or -independent mechanisms.

Source

Klinicheskaja Laboratornaia Diagnostika. (4):18-22, 1994.

Abstract

Changes in fluorescence intensity of blood lymphocytes of patients with somatic and pretumorous diseases of the gastrointestinal system were detected: fluorescence intensity of lymphocytes fluorochrome-stained with acridine orange was increased in chronic gastric and pancreatitis whereas in patients with pretumorous diseases this parameter could be both increased and decreased. Exposure to an extra stress factor, such as low-dose ionizing radiation, manifested by increased fluorescence intensity of normal subjects' blood lymphocytes, a certain normalization

of this parameter in patients with somatic diseases, and an increase of the amplitude of shifts vs. the normal range in patients with pretumor gastrointestinal diseases. Fluorescent analysis of lymphocytes helps integrally assess the functional activity of immunohomeostasis.

Title

Alteration of irradiated shuttle vector processing by exposure of human lymphoblast host cells to single or split gamma-ray doses.

Source

International Journal of Radiation Biology. 65(2):157-64, 1994 Feb.

Abstract

The repair of damaged DNA by mammalian cells exposed to single or split doses of radiation was probed with shuttle vector pZ189. Human lymphoblast hosts who received a single 120 cGy dose 2 h before transfection with 2500 cGy-damaged pZ189 yielded a two-fold higher frequency of progeny plasmids with mutations in their supF-tRNA target genes than did unirradiated host cells. Delaying transfection for 12 h, however, reduced the mutation frequency by half versus unirradiated controls. Plasmid survival was also affected by the time between host cell irradiation and transfection. Splitting doses of 50-500 cGy into two equal fractions separated by 4 h lowered mutation frequency and increased plasmid survival compared with equivalent acute doses; increasing the interval between dose fractions to 8 h, however, lowered plasmid survival compared with acute doses. Sequence analyses of the target gene in mutant plasmids revealed increased multiple-base substitution mutations among progenies recovered from irradiated hosts, indicating enhanced excision repair. These findings support modulation of mammalian cell DNA repair by ionizing radiation, disclose the transient nature of the effect of radiation on DNA repair, and demonstrate a quantitative difference in the effectiveness of single and split doses.

Title

T cells are the cellular target of the proliferation-augmenting effect of chronic low-dose ionizing radiation in mice.

Source

Radiation Research. 139(1):47-52, 1994 Jul.

Abstract

The proliferative response to mitogenic stimulation by splenocytes can be augmented by exposing mice to whole-body, chronic, intermittent low doses of ionizing radiation, referred to here as low-dose irradiation. The purpose of this study was to identify the cell(s) in the spleen which is responsive to the proliferation-augmenting effect of low-dose irradiation, i.e., the cellular target. C57BL/6 mice were subjected to low-dose irradiation (0.04 Gy/exposure/day, 5 consecutive days/week, 2 weeks) or to sham irradiation. Three days after the last exposure, spleens were removed, separated into cell fractions which were nonadherent and adherent to plastic surfaces and reconstituted in various combinations, and their proliferative responses to various mitogens were determined. Highly purified T cells were also used in place of the nonadherent cell fraction in the reconstitution studies. The target cells were shown to be T cells. The target T cells of low-dose-irradiated mice possessed elevated constitutive levels of HSP-70 mRNA and HSP-72, and they responded to T-cell receptor-specific anti-CD3 stimulation by producing more HSP-70 mRNA and HSP-72 and by proliferating more extensively than T cells of sham-irradiated mice.

Title

Activation of nuclear factor kappa B in human lymphoblastoid cells by low-dose ionizing radiation.

Source

Radiation Research. 138(3):367-72, 1994 Jun.

Abstract

Nuclear factor kappa B (NF-kappa B) is a pleiotropic transcription factor which is involved in the transcriptional regulation of several specific genes. Recent reports demonstrated that ionizing radiation in the dose range of 2-50 Gy results in expression of NF-kappa B in human KG-1 myeloid leukemia cells and human B-lymphocyte precursor cells; the precise mechanism involved and the significance are not yet known. The present report demonstrates that even lower doses of ionizing radiation, 0.25-2.0 Gy, are capable of inducing expression of NF-kappa B in EBV-transformed 244B human lymphoblastoid cells. These results are in a dose range where the viability of the cells remains very high. After exposure to 137Cs gamma rays at a dose rate of 1.17 Gy/min, a maximum in expression of NF-kappa B was seen at 8 h after a 0.5-Gy exposure. Time-course studies revealed a biphasic time-dependent expression after 0.5-, 1- and 2-Gy exposures. However, for each time examined, the expression of NF-kappa B was maximum after the 0.5-Gy exposure. The expression of the p50 and p65 NF-kappa B subunits was also shown to be regulated differentially after exposures to 1.0 and 2.0 Gy.

Title

Radiosensitivity of ataxia-telangiectasia, X-linked agammaglobulinemia, and related syndromes using a modified colony survival assay.

Source

Cancer Research. 54(10):2544-7, 1994 May 15.

Abstract

We used a modified colony survival assay to measure the sensitivity to ionizing radiation of more than 50 lymphoblastoid cell lines from normal individuals and from patients with ataxia-telangiectasia, Nijmegen breakage syndrome variants, and X-linked agammaglobulinemia. All of these disorders are associated with an increased frequency of cancer. Lymphoblastoid cell lines from patients with ataxia-telangiectasia complementation groups A, C, D, and E; ATFresno; Nijmegen breakage syndrome variants V1 and V2; and X-linked agammaglobulinemia showed marked radiosensitivity, whereas ataxia-telangiectasia heterozygotes were similar

to controls. Friedreich's ataxia is not associated with increased cancer risk; lymphoblastoid cell lines from two such patients showed normal radiosensitivity. Taken together, these results suggest that some forms of X-ray sensitivity and cancer susceptibility share a common mechanism, such as an enzyme that is necessary both for the repair of radiation damage to DNA and for gene rearrangements during V(D)J recombination.

Title

Chromosomal adaptive response in human lymphocytes. [Review]

Source

Radiation Research. 138(1 Suppl):S9-12, 1994 Apr.

Abstract

It has been almost a decade since the initial report of Olivieri et al. (Science 223, 594-597, 1984) on the phenomenon they termed "adaptive response of human lymphocytes to ionizing radiation." Although a number of reports have appeared since then, our understanding of this response is still incomplete. In this paper, the author presents an analysis of the area using published data in the literature as well as unpublished data from the author's laboratory. Most of the data come from measurements of the effects of low-dose radiation on chromatid-type aberrations induced in late S/early G2 phase cells. Exposure of lymphocytes to low doses of ionizing radiation can affect a certain fraction of aberrations induced by a subsequent high dose. Chemicals have been substituted for ionizing radiation as either inducers or challenging agents; however, their use has not provided specific information about inducing signals or target lesions. The working hypothesis in studies on adaptive response is that a repair activity is induced that acts on lesions in DNA. Although there is promising evidence that new and/or altered synthesis of proteins is required to observe reductions in aberrations, the gap between hypothesis and evidence is still wide. Co-ordinate analysis of different end points in individual cells should help to close this gap. While an adaptive response can be induced under a range of conditions, there is no good explanation for the inter/intradonor variability observed. The contributors to this variation need to be identified. [References: 30]

Title

Evidence for induced radioresistance from survival and other end points: an introduction.

Source

Radiation Research. 138(1 Suppl):S5-8, 1994 Apr.

Abstract

A substantial body of data published during the past 30 years makes a strong case for the existence of cellular radioprotective mechanisms that can be up-regulated in response to exposure to small doses of ionizing radiation. Either these "induced" mechanisms can protect against a subsequent exposure to radiation that may be substantially larger than the initial "priming" or "conditioning" dose, or they may influence the shape of the survival response to single doses so that small radiation exposures are more effective per unit dose than larger exposures above a threshold where the induced radioprotection is triggered. Evidence for these effects comes from studies in vitro with protozoa, algae, higher plant cells, insect cells, mammalian and human cells, and studies on animal models in vivo. Work at the molecular level is now confirming that changes in levels of some cytoplasmic and nuclear proteins, and the increased expression of some genes, may occur within a few hours or even minutes of irradiation. This would be sufficiently quick to explain the phenomenon of induced radioresistance although the precise mechanism, whether by repair, cell cycle control or some other process, remains yet undefined.

Title

Radioadaptation to the mutagenic effect of ionizing radiation in human lymphoblasts: molecular analysis of HPRT mutants.

Source

Cancer Research. 54(7 Suppl):1924s-1928s, 1994 Apr 1.

Abstract

A 70% reduction of HPRT- mutant frequency in radioadapted human lymphoblastoid cells has been reported, as analyzed by the Southern blot method (O. Rigaud et al., Radiat. Res., 133: 94-101, 1993). The data reported here extend the previous molecular analysis to a collection of 118 mutants. Structural rearrangements of the HPRT gene were determined using the multiplex polymerase chain reaction assay. This allows us to define more precisely the deleted exons in mutants and to ensure the absence of small alterations in exons among mutants with no detectable change after Southern analysis. The phenotype of these latter mutants is likely to be due to point mutations. Overall results of both Southern and multiplex polymerase chain reaction analyses confirm that the proportion of deletion-type mutations is decreased in adapted cells (42%) compared to that in mutants treated with the high dose alone (77%). Mutants with no change at the HPRT gene level were further characterized with respect to their HPRT gene expression. The vast majority of adapted mutants (86%) were still expressing mRNA, whereas HPRT transcripts were detected in only 56% of the mutants induced by the high dose alone. From these data and those reported by others, possible mechanisms underlying the adaptive

response are proposed.

Title

Radiation-induced damage, repair and exchange formation in different chromosomes of human fibroblasts determined by fluorescence in situ hybridization.

Source

Radiation Research. 137(1):34-43, 1994 Jan.

Abstract

We have used fluorescence in situ hybridization with whole-chromosome probes for human chromosomes 1, 4, 8 and 13 to investigate the extent to which the induction of damage and its repair after exposure to ionizing radiation is distributed randomly among these chromosomes. All the studies were performed with AG1522 human fibroblasts irradiated with 6 Gy and maintained in a nondividing state for at least 6 h after irradiation except for the measurements of initial damage. The extent of initial damage was determined by fusion of the cells immediately after irradiation with metaphase HeLa cells to obtain premature chromosome condensation (PCC). Breaks and exchanges were also scored by PCC 24 h after irradiation and in metaphase spreads at the first division after irradiation. The data obtained were consistent with random breakage and repair in these chromosomes. Comparing PCC 24 h after irradiation with first metaphase, there was a deficit in aberrations at metaphase, particularly in unrejoined breaks, implying loss or slowing of cells containing aberrations prior to the first division. An analysis of dicentrics and translocations in chromosome 4 at first and in subsequent divisions showed

that there was an equal number of dicentrics and translocations at first metaphase with loss of dicentrics, but no loss of translocations in subsequent divisions. These data are supportive of the hypothesis tht the total number of chromosome aberrations in cells can be estimated from a single chromosome pair.

Title

Hypersensitivity of lymphoblastoid lines derived from ataxia telangiectasia patients to the induction of chromosomal aberrations by etoposide (VP-16).

Source

Mutation Research. 290(2):265-72, 1993 Dec.

Abstract

Mammalian DNA topoisomerase II represents the cellular target of many antitumor drugs, such as epipodophyllotoxin VP-16 (etoposide). The mechanism by which VP-16 exerts its cytotoxic and antineoplastic actions has not yet been firmly established, although the unique correlation between sensitivity to ionizing radiation and to topoisomerase II inhibitors suggest the involvement of DNA double-strand breaks. In the present study we analyzed the chromosomal sensitivity of lymphoblastoid cell lines derived from ataxia telangiectasia (AT) patients to low concentrations of the drug. Our results indicate that AT derived cells are hypersensitive to the clastogenic activity of VP-16 either when the drug is present for the whole duration of the cell cycle or specifically in the G2 phase, confirming that the induction of DNA double strand breaks, to which AT cells seem typically sensitive, could have an important role in the biological activity of VP-16.

Title

DNA strand breaks and chromosomal aberrations induced by H2O2 and 60Co gamma-radiation.

Source

Mutation Research. 289(2):197-204, 1993 Oct.

Abstract

DNA strand breaks and chromosomal aberrations (CAs) were studied in human cells treated with hydrogen peroxide or with ionizing radiation. DNA strand breaks could be produced at dose levels of H2O2 much lower than

those which induced CAs. Doses as low as 0.5 mM of H₂O₂ produced about as many DNA strand breaks as 2 Gy of ⁶⁰Co gamma-radiation. On the other hand, as much as 20 mM H₂O₂ produced only half as many CAs as 1 Gy of ⁶⁰Co gamma-radiation. The different mechanisms involved in the production of human genetic damage by H₂O₂ and gamma-radiation are discussed.

Title

HPRT-mutant frequency and lymphocyte characteristics of workers exposed to ionizing radiation on a sporadic basis: a comparison of two exposure indicators, job title and dose.

Source

Mutation Research. 319(1):61-70, 1993 Sep.

Abstract

Using the clonal HPRT-mutant frequency assay, mutant frequencies of humans have been shown to rise following exposure to large doses of mutagens during radiotherapy, chemotherapy or after an atom bomb explosion. Success in relating mutant frequencies to exposure to high levels of mutagens has encouraged researchers to examine the effects of lower doses, such as those found among workers exposed at their jobs. In order to relate low doses of mutagens to biological effects, accurate characterization of exposure is critical, but most occupational studies are forced to use gross measures of exposure derived from job title or professional judgments as to potential exposure. Mutant frequencies and other relevant lymphocyte characteristics of 58 industrial workers were related to exposure status in two ways. When workers were classed as "exposed" or "unexposed" to ionizing radiation, no difference in any biological variable was seen between the two groups. When dosimeter readings were used as the exposure indicator, significant relationships appeared between dose and mutant frequency and CD4/CD8 lymphocyte subpopulation ratios. Mutant frequency was also positively related to age and smoking status. The time course of exposure and of appearance of mutant cells is discussed and it is suggested that this relationship receive attention in occupational studies of genotoxic effects.

Title

Cytogenetic study in lymphocytes from children exposed to ionizing radiation after the Chernobyl accident.

Source

Mutation Research. 319(1):55-60, 1993 Sep.

Abstract

The present study concerns the monitoring of children from the Byelorussian, Ukrainian and Russian republics exposed to the fall-out of the Chernobyl accident. Cytogenetic analyses have been performed on 41 children coming from different areas and exhibiting varying amounts of ¹³⁷Cs internal contamination, as evaluated by whole-body counter (WBC) analysis. On a total of 28,670 metaphases scored, radiation-induced chromosome damage is still present, although at a very low frequency. Due to the very low fraction of dicentrics, because of the time elapsed from the accident and the relatively low doses of exposure, radiobiological dosimetry is not possible for these children. However, considering that the WBC data indicate that the children are still exposed to ¹³⁷Cs contamination, the observed occurrence of stable chromosome rearrangements and breaks may represent the persisting effect of continuous low doses of radiation. The present study also indicates that the parallel use of internal contamination dosimetry and cytogenetics could be usefully employed to monitor individual exposure to radiation and to define further management measures.

Title

Enhanced DNA repair in lymphocytes of Down syndrome patients: the influence of zinc nutritional supplementation.

Source

Mutation Research. 295(3):105-11, 1993 Aug.

Abstract

Oral zinc supplementation is able to correct zinc deficiency and some immune defects present in Down's syndrome (DS), while other beneficial effects can be predicted because of the broad spectrum of biochemical pathways and the great variety of enzymes which depend on zinc bio-availability. To test if the maintenance of DNA integrity is also affected by zinc supplementation, DNA damage and repair after gamma-radiation was studied by alkaline elution assay in phytohemagglutinin-stimulated lymphocytes from Down's syndrome children before and after an oral zinc supplementation given for 4 months to correct their immune defects. In comparison with lymphocytes from normal children the DNA damage induction after ionizing radiation in DS lymphocytes both before and after zinc supplementation was normal. On the other hand, the rate of DNA repair in DS was highly and significantly accelerated before zinc treatment. After supplementation with zinc sulfate, the DNA repair rate was consistently slowed down becoming similar to that of control subjects. This is the first demonstration that a nutritional intervention in humans is apparently able to modify the biochemical steps which control the rate of DNA repair.

Cytogenetic analysis of lymphocytes from hospital workers occupationally exposed to low levels of ionizing radiation.

Source

Mutation Research. 286(2):275-9, 1993 Apr.

Abstract

Cytogenetic studies were performed in lymphocytes from hospital workers exposed to low doses of radiation (1.6-42.71 mSv). When compared with controls, exposed workers showed a significant increase in structural chromosome-type aberrations, acentric fragments being the most frequent alteration. Our results suggest that acentric fragments are good indicators of exposure to very low doses of radiation, although no dose-effect correlation was observed. The incidence of numerical abnormalities (hyperdiploidy) was significantly increased.

Radiation induced micronuclei in subpopulations of human lymphocytes.

Source

Mutation Research. 286(2):181-8, 1993 Apr.

Abstract

The micronucleus expression in T-helper, T-suppressor and B lymphocytes of the peripheral blood was studied after in vitro exposure to high (2.5 Gy and 5 Gy) and low (0.5 Gy and 1 Gy) doses of ionizing radiation. Investigations were carried out by combining the micronucleus assay with immunofluorescence staining using subpopulation specific antibodies. While in the higher dose range B cell proliferation was inhibited nearly completely-so that micronuclei could not be expressed-we found after exposure to lower doses that B cells were the lymphocyte subpopulation which was most sensitive to micronucleus induction. Among the T cell population, the T-suppressor subset revealed a higher yield of micronuclei than T-helper cells, whereas with regard to the effect of radiation on proliferative ability, T-helper cells reacted more sensitivity than the T-suppressor lymphocytes. Our studies provide insight into the effect of radiation exposure on the micronucleus expression of lymphocyte subpopulations and new information which may be useful for the further development of biological dosimetry.

Title

Induction of micronuclei by bleomycin in G0 human lymphocytes: II. Potentiation by radioprotectors.

Source

Environmental & Molecular Mutagenesis. 21(2):136-43, 1993.

Abstract

Dimethylsulfoxide (DMSO) and WR-1065 are radioprotectors, in that they reduce the effectiveness with which ionizing radiation causes genetic damage. Unlike their protective effects with radiation, these agents potentiate the induction of micronuclei by bleomycin in the cytokinesis-block assay in G0 human lymphocytes. High concentrations of DMSO (1 M) are required to cause potentiation. In contrast, WR-1065 causes dose-dependent potentiation at relatively low concentrations (1.25 to 10 mM). Cytogenetic analysis supports the results from the micronucleus assay, showing higher levels of genetic damage induced by the combination of bleomycin with DMSO or WR-1065 than by bleomycin alone. Possible mechanisms of potentiation are proposed.

Title

Evidence that the adaptive response of human lymphocytes to ionizing radiation acts on lethal damage in nonaberrant cells.

Source

Mutation Research. 301(3):171-6, 1993 Mar.

Abstract

In a previous study we found that a cytogenetic adaptive response could lead to increases in survival if there was a sufficient increase in nonaberrant cells (Shadley and Dai, 1992). Since the high challenge doses used produced mainly multiply aberrant cells, we suggested using challenge doses that gave mainly singly aberrant cells in order to improve detection of a survival adaptive response. To test this, human lymphocytes from 6 donors were exposed in the first G1 phase to 5 cGy of X-rays, followed by 100 cGy 6 h later. Nearly all of the aberrant cells bore only one chromosome aberration with this challenge dose, and in agreement with our proposal, survival adaptive responses were seen in 4 of 6 donors. A near 1:1 relationship between the % nonaberrant cells and % survival was found with 100 cGy, suggesting that the lymphocyte populations scored in the survival and aberration assays were representative of each other. However, the increase in nonaberrant cells was not sufficient to account for the increase in survival. Thus, a large fraction of the increase in survival

was due to a decrease in lethal damage in cytologically nonaberrant cells. Such damage could range from sub-microscopic lesions, to larger alterations not visible in Giemsa-stained cells. In conjunction with adaptive response studies of others, these results intimate that the adaptive response affects damage at different levels of chromosomal hierarchy (i.e. from the chromosome to DNA). The process(es) responsible for the effects observed in this study may act on lethal, rather than mutagenic lesions.

Title

Effects of low-doses of X-rays on the expression of human cell surface CD2 antigen in CD2+ CHO cells.

Source

International Journal of Radiation Biology. 64(5):621-6, 1993 Nov.

Abstract

Thioguanine resistant CHO cells (HPRT-) were stably cotransfected with pSV2-gpt and pi H3-CD2 vectors using the calcium phosphate coprecipitation technique. The effects of single low doses of ionizing radiation were studied in a CD2+ CHO clone. The CD2+ phenotype responsible for binding sheep erythrocytes and rosette formation, was not affected by X-rays doses in the range 2-6 cGy. However, after 10 cGy of X-irradiation, 50% of the cells lost the CD2+ phenotype. These results suggest that this CD2+ clone might be a very sensitive indicator of very low X-ray doses. The implications of the phenotypic changes, observed after very low doses of irradiation, are discussed.

Title

Validation of chromosome painting as a biodosimeter in human peripheral lymphocytes following acute exposure to ionizing radiation in vitro.

Source

International Journal of Radiation Biology. 64(1):27-37, 1993 Jul.

Abstract

Fluorescence in situ hybridization with chromosome-specific composite DNA probes ('chromosome painting') appears to be a useful tool for quantifying symmetrical cytogenetic damage. However, a thorough comparison between chromosome painting and the conventional methods of GTG-banding and dicentric analysis has not been performed. We have undertaken the validation of chromosome painting using human blood exposed in vitro to

¹³⁷Cs gamma-rays at doses ranging from 0 to 400 cGy, then cultured according to standard procedures and harvested at 52 h. For painting, bound probes were detected either with fluoresceinated avidin and counterstained with propidium iodide, or with ChromoBlue WCP Probe and Giemsa. The first approach utilizes ultraviolet excitation in which painted chromosomes appear yellow and the remaining chromosomes appear red. The ChromoBlue labelling approach requires ordinary light microscopy in which painted chromosomes appear dark blue and the remaining chromosomes appear light blue. With each method, exchanges between painted and unpainted chromosomes appear bi-coloured. Because only a fraction of all possible exchanges are detected, the number of metaphases examined is adjusted according to the fraction of the genome painted. We have performed painting by several methods, including fluorescence with chromosome 4 probe alone, fluorescence with probes for chromosomes 1, 3 and 4 simultaneously, and chromogenic painting with chromosome 4 probe alone. The results obtained by the various painting methods were compared with GTG-banded cells which were examined for both translocations and dicentrics. In addition, unbanded metaphases stained with Giemsa were scored for dicentrics. Our data show that the frequency of chromosome exchanges detected by painting and banding agree with each other and with the number of dicentrics seen in unbanded cells, at least at doses of < or = 200 cGy.

Title

Biological dosimetry of absorbed radiation by C-banding of interphase chromosomes in peripheral blood lymphocytes.

Source

International Journal of Radiation Biology. 63(3):349-54, 1993 Mar.

Abstract

Induction of premature chromosome condensation enables direct observation of radiation-induced cytogenetic damage in non-stimulated, interphase, human peripheral blood lymphocytes. This phenomenon can be explored in radiation protection for biological dosimetry in instances of accidental exposure to ionizing radiation. Quantification of an exposure by means of this approach has been limited so far mainly to the analysis of chromosome fragments. This limitation is due to the fact that conventional Giemsa staining of prematurely condensed chromosomes (PCCs) does not allow visualization of the centromeric regions and, as a result, the identification of dicentrics, centric rings and acentric fragments. In the present report a C-banding procedure, refined to avoid swelling and chromosome distortion of freshly prepared PCCs spreads, is used to identify such aberrations in non-stimulated human lymphocytes. The method allows immediate banding of the centromeric regions and enables scoring of aberrations within a time interval (3-4 h after blood sample withdrawal) that is only a fraction of that normally required when cells stimulated to

proliferate are analysed at metaphase. The dose-response for dicentric and centric rings measured in interphase lymphocytes was found to be similar to that obtained at metaphase. Measurement of dicentric and centric rings in prematurely condensed chromosomes of human lymphocytes would provide valuable information on radiation dose estimates, especially in cases of extreme urgency.

[Evaluation of chromosome damage induced by X-rays in human lymphocytes].
[Spanish]

Source

Revista Medica de Chile. 121(11):1240-4, 1993 Nov.

Abstract

Aiming to assess the DNA damage induced by low doses of ionizing radiations, control and X-ray irradiated (10 rad) whole blood cultured lymphocytes were treated with the following G2 DNA synthesis and repair inhibitors: caffeine (caff), hydroxyurea (hu), aphidicolin (aphi) and 1-beta-D-arabinofuranocylcytosine (ara C). The effects of each inhibitor or its combinations were assessed counting the number of chromatid breaks, which were considered equivalent to unrepaired lesions. Our results showed that 5 mM caff and 2.5 mM Hu were the inhibitors that separately produced the higher frequency of chromatid breaks. Likewise, the combination of 5 mM caff, aphi 5 micrograms/ml and ara C 1 microM, or 2.5 mM HU and 0.1 microM ara C, allowed to detect the highest number of induced lesions arriving G2 lesions. We therefore propose that the use of these two last inhibitor combinations, can be used as alternative methods to detect DNA damage induced by low levels of ionizing radiation, in lymphocytes of occupationally exposed individuals.

Title

Mechanisms for induction of mutations and chromosome alterations.

Source

Environmental Health Perspectives. 101 Suppl 3:225-9, 1993 Oct.

Abstract

Genotoxic agents induce chromosomal alterations, such as aberrations, micronuclei, and sister chromatid exchanges as well as mutations both in vivo and in vitro. Ionizing radiation and typical radiomimetic agents such as bleomycin are very efficient inducers of chromosomal aberrations.

The type of aberrations induced by these agents are cell-cycle dependent, i.e., chromosome type in pre-replication stages and chromatid type in post-replication stages of the cell cycle. Under optimal DNA repair conditions, DNA double-strand breaks (DSBs) appear to be the most important lesion responsible for the production of aberrations. In human lymphocytes, fast-repairing DSBs lead to exchange-type aberrations. The fact that the dose-response curves for induction of exchange aberrations induced by ionizing radiation are similar in vitro and in vivo allows one to use the yield of induced aberrations to estimate absorbed radiation dose in the case of accidents. In this respect, frequencies of translocations detected by the chromosome painting technique appear to be more sensitive. Mutations do not express immediately after exposure and require an expression time before they can be detected. In humans, it is estimated that for the mutations induced in bone marrow, it takes about 2 months for them to express and to be detected in peripheral blood lymphocytes. Hence, frequency of mutations is of limited value for estimating radiation doses immediately after an accident. This holds true for chemical exposure as well.(ABSTRACT TRUNCATED AT 250 WORDS)

Title

Somatic cell gene mutations in humans: biomarkers for genotoxicity.

Source

Environmental Health Perspectives. 101 Suppl 3:193-201, 1993 Oct.

Abstract

Somatic cell gene mutations arising in vivo in humans provide biomarkers for genotoxicity. Four assays, each measuring changes in a different "recorder" gene, are available for detecting mutations of the hemoglobin (Hb) and glycophorin A (gpa) genes in red blood cells and the hypoxanthine-guanine phosphoribosyltransferase (hprt) and HLA genes in T-lymphocytes. Mean adult background mutant frequencies have been established; i.e., approximately 4×10^{-8} (Hb), $5-10 \times 10^{-6}$ (hprt), $10-20 \times 10^{-6}$ (gpa) and 30×10^{-6} (HLA). All the assays have now been used in studies of individuals exposed to physical and/or chemical genotoxic agents, and all have shown elevated values following exposures; examples are presented. In addition to quantitation, the lymphocyte assays allow molecular analyses of in vivo mutations, the definition of background and induced mutational spectra, and the search for unique changes for characterizing specific mutagens. The HPRT system currently has the largest database in this regard. Approximately 15% of adult background hprt mutations are due to gross structural alterations (primarily deletions) having random breakpoints; 85% result from "point" changes detected only by sequencing. In contrast, a specific intragenic deletion due to DNA cleavage at specific sites characterizes fetal hprt mutations, implicating a developmental mistake in their genesis. (This kind of developmental mistake in other genes is frequently observed in

lymphoid malignancies.) Mutational spectra are just beginning to be defined for induced hprt mutations, e.g., ionizing radiation produces large deletions.(ABSTRACT TRUNCATED AT 250 WORDS)

Title

Interleukin-1 and tumor necrosis factor-alpha as radio- and chemoprotectors of bone marrow. [Review]

Source

Bone Marrow Transplantation. 12(6):551-63, 1993 Dec.

Abstract

Administration of interleukin 1 (IL-1) or tumor necrosis factor-alpha (TNF alpha) protects bone marrow precursor cells (BMPC) from ionizing radiation and antineoplastic drugs. The time of injection is critical: the best protective results being obtained when cytokines are given around 24h prior to the induced injury. Multiple daily cytokine injections that precede irradiation or drug administration are more effective than single ones although single doses are quite effective at increasing survival in mice. Protection is positively correlated with both rapid granulocyte recovery and BMPC survival. Mechanisms involved in BMPC radioprotection include: (1) push to the S/G2 + M or arrest in the G0 phases of the cell cycle by IL-1 or TNF alpha, respectively, and (2) induction of mitochondrial manganous superoxide dismutase synthesis. For BMPC chemoprotection, proposed mechanisms are: (1) increase of aldehyde dehydrogenase synthesis, and (2) modulation of multiple-drug resistant gene expression. Stimulation of glutathione synthesis in BMPC could be operating in both radio- and chemoprotection. These findings point to the relevance of IL-1 or TNF alpha in cancer therapy as a means of reducing BMPC sensitivity to cytoreductive drugs or irradiation (including radioimmunotherapy) as well as in in vitro tumor cell purging with drugs in autologous BMT. Prior administration of these cytokines should be also considered for people in imminent danger of exposure to radiation. [References: 165]

Title

A comparison of micronucleus frequency and radiation survival in lymphoblastoid cell lines.

Source

Mutagenesis. 8(6):569-75, 1993 Nov.

Abstract

The relationship between the formation of micronuclei (MN) following the treatment of cell lines with ionizing radiation and the radiation survival of cell lines is important as the MN assay has the potential to predict radiation survival. Studies investigating the relationship have reached conflicting conclusions. We examined the relationship between MN formation and radiation survival measured by a clonogenic assay in six lymphoblastoid cell lines over a dose range of 0-2.0 Gy. We did not find a predictive relationship between the radiation induced MN frequency and the radiation survival in these cell lines. Possible reasons for the lack of correlation include variations in the percentage of scorable cells after irradiation and culture with cytochalasin B, different numbers of cells in the G1 phase of the cell cycle at the time of irradiation, a greater toleration of the loss of MN by hyperdiploid cell lines compared to diploid cell lines and quantitative differences in the conversion of chromosomal fragments into MN for the cell lines.

[Immune status of people participating in the clean-up of after-effects of the Chernobyl Nuclear Power Plant accident living in the industrial region of Donbass]. [Russian]

Source

Gematologiya i Transfuziologiya. 38(7):39-42, 1993 Jul-Aug.

Abstract

The examination of 286 subjects exposed to radiation hazards when taking part in liquidation of the Chernobyl accident aftereffects was performed to compare persons living under ecologically unfavourable conditions (significant air pollution due to heavy industry) against those living in relatively comfortable environment. It was found that immune status of the former displayed imbalance. In the latter immunity was much less damaged. The findings suggest a conclusion on the role of environmental factors in immunological disturbances in subjects exposed to small doses of ionizing radiation.

Synergistic effects of ionizing radiation and 60 Hz magnetic fields.

Source

Bioelectromagnetics. 14(6):545-51, 1993.

Abstract

Experiments designed to evaluate the synergistic production of clastogenic effects by ionizing radiation and 60 Hz magnetic fields were performed using human lymphocytes from peripheral blood. Following exposure to

ionizing radiation, cells were cultured in 60 Hz magnetic fields having field strengths up to 1.4 mT. Cells exposed to both ionizing radiation and 60 Hz magnetic fields demonstrated an enhanced frequency of near tetraploid chromosome complements, a feature not observed following exposure to only ionizing radiation. The results are discussed in the context of a multiple-stage model of cellular transformation, employing both initiating and promoting agents.

Title

Caffeine enhanced measurement of mutagenesis by low levels of gamma-irradiation in human lymphocytes.

Source

Somatic Cell & Molecular Genetics. 19(5):423-9, 1993 Sep.

Abstract

The well-known action of caffeine in synergizing mutagenesis (including chromosome aberrations) of agents like ionizing radiation by inhibition of cellular repair processes has been incorporated into a rapid procedure for detection of mutagenicity with high sensitivity. Effects of 5-10 rads of gamma-irradiation, which approximate the human lifetime dose accumulation from background radiation, can be detected in a two-day procedure using an immortalized human WBC culture. Chromosomally visible lesions are scored on cells incubated for 2 h after irradiation in the presence and absence of 1.0 mg/ml of caffeine. An eightfold amplification of scorable lesions is achieved over the action of radiation alone. This approach provides a closer approximation to absolute mutagenicity unmitigated by repair processes, which can vary in different situations. It is proposed that mutagenesis testing of this kind, using caffeine or other repair-inhibitory agents, be employed to identify mutagens in their effective concentrations to which human populations may be exposed; to detect agents such as caffeine that may synergize mutagenic actions and pose epidemiologic threats; and to discover effective anti-mutagens. Information derived from the use of such procedures may help prevent cancer and newly acquired genetic disease.

Inhibition of poly(ADP-ribose) polymerization preserves the glutathione pool and reverses cytotoxicity in hydrogen peroxide-treated lymphocytes.

Source

Biochemical Pharmacology. 46(12):2139-44, 1993 Dec 14.

Abstract

DNA damage caused by oxygen radicals activates poly(ADP-ribosyl) polymerase (pADPRP), a nuclear enzyme that utilizes NAD⁺ as substrate. It has been demonstrated that pharmacological inactivation of pADPRP rescues human lymphocytes damaged by oxygen radicals, but not those damaged by equitoxic doses of ionizing radiation. In the present paper we demonstrate that the NAD⁺ pool decreases after both damaging treatments and is preserved in a similar fashion by pADPRP inhibition. On the contrary, the ATP pool, cell energy charge and reduced thiols are decreased only by the administration of oxygen radicals, and are preserved if poly(ADP)ribosylation is inhibited. In fact, treatment with oxidant agents depletes the cell energy pools owing to the simultaneous demands of the glutathione (GSH)/NADPH cycle and pADPRP-driven NAD⁺ consumption, while in irradiated cells only the latter mechanism operates. We suggest that, when pADPRP is inhibited, enough energy is available for the preservation of cell thiols, thereby allowing oxidant-treated cells to survive and undergo mitosis. Thus, GSH and energy shortage appear to be the main cause of cell death in oxidant-injured cells.

Title

Ionizing radiation and UV induction of p53 protein by different pathways in ataxia-telangiectasia cells.

Source

Oncogene. 8(12):3307-12, 1993 Dec.

Abstract

Cell cycle anomalies have been described in ataxia-telangiectasia cells after exposure to ionizing radiation. A recent report demonstrates that cells from these patients lack the ionizing radiation-induced increase in p53 protein seen in controls. We report here that an ionizing radiation-induced p53 response is reduced and/or delayed in cells from four ataxia-telangiectasia complementation groups. On the other hand, p53 induction is normal in all A-T complementation groups after exposure to UV-B light, an agent to which these cells are not hypersensitive. Specific inhibitors of protein kinase C and serine/threonine phosphatases prevented the radiation induction of p53 protein. Agents that produced double-strand breaks in DNA and/or inhibition of transcription caused an induction of p53 in the absence of radiation in control cells but not in ataxia-telangiectasia, but inhibitors of cell cycle progression such as mimosine and aphidicolin led to an increase in p53 in both cell types in the absence of radiation. These results suggest that there is more than one signal transduction pathway responsible for activation of p53, one of which is less efficient in ataxia-telangiectasia cells.

27(4):899-906, 1993 Nov 15.

Abstract

PURPOSE: Detailed comparative analyses of the radiation sensitivity of primary clonogenic blasts from children with acute lymphoblastic leukemia (ALL) were performed to achieve a better understanding of clinical radiation resistance in ALL. **METHODS AND MATERIALS:** The radiation sensitivity of primary clonogenic blasts from 74 children with newly diagnosed acute lymphoblastic leukemia (ALL) was analyzed using leukemic progenitor cell (LPC) assays. Primary bone marrow blasts from all 74 patients were exposed to ionizing radiation and subsequently assayed for LPC-derived blast colony formation. Radiation survival curves of primary clonogenic blasts (i.e., LPC) were constructed for each of the newly diagnosed patients using computer programs for the single-hit multitarget as well as the linear quadratic models of cell survival. **RESULTS:** A marked interpatient variation in intrinsic radiation sensitivity was observed between LPC populations. The SF2 values ranged from 0.01 to 1.00 (median: 0.36; mean \pm SE = 0.40 ± 0.03), and the alpha values ranged from 0.00 Gy⁻¹ to 3.27 Gy⁻¹ (median: 0.280 Gy⁻¹; mean \pm SE = 0.43 ± 0.09 Gy⁻¹). Patients were divided into groups according to their sex, age, WBC at diagnosis, cell cycle distribution of leukemic blasts, and immunophenotype. Only immunophenotype provided a significant correlation with the intrinsic radiation sensitivity of LPC. Patients with B-lineage ALL had higher SF2 (0.47 ± 0.04 vs. 0.31 ± 0.05 , $p < 0.05$) and smaller alpha values (0.43 ± 0.09 Gy⁻¹ vs. 0.65 ± 0.10 Gy⁻¹, $p < 0.05$) than T-lineage ALL patients, consistent with greater intrinsic radiation resistance at the level of LPC. Notably, 43% of B-lineage ALL cases, but only 27% of T-lineage ALL cases had LPC with SF2 \geq 0.5. Similarly, 66% of B-lineage ALL cases, but only 37% of T-lineage ALL cases had LPC with alpha values \leq 0.4 Gy⁻¹. Combining the two indicators of radiation resistance, we found that only 34% of the B-lineage ALL patients had none of the two parameters in the respective critical regions (alpha \leq 0.4 Gy⁻¹; SF2 \geq 0.5), while 63% of the T-lineage patients had none ($p < 0.05$). In multivariate analyses, the immunophenotypic B-lineage affiliation was the only significant predictor of radiation resistance at the level of LPC. Whether alone or in combination, none of the other variables examined, including sex, age, WBC, in vitro plating efficiency, S-phase index, and proliferation index were significantly correlated with the radiation sensitivity or resistance of LPC. **CONCLUSION:** These results offer unprecedented evidence for an association between composite immunophenotype (viz., B-lineage ALL vs T-lineage ALL) and radiation

resistance that may form a basis for modifying radiation conditioning regimens.

Title

A role for mitochondrial DNA in the pathogenesis of radiation-induced myelodysplasia and secondary leukemia. [Review]

Source

Leukemia Research. 17(11):907-13, 1993 Nov.

Abstract

The onset of acute myeloid leukemia following ionizing radiation or alkylating agent exposure is antedated months to years by the development of 'preleukemia', or secondary myelodysplastic syndrome (sMDS). Mitochondrial abnormalities induced by chloramphenicol and clonal deletions of mitochondrial DNA (mt DNA) in the bone marrow create hematological defects similar to sMDS, and abnormal dimers of mt DNA are observed in acute leukemia. This suggests a role for mt DNA in the pathogenesis of sMDS and secondary leukemia. We outline disparate experimental evidence to support this concept and suggest a role for select protease inhibitors in the clinical management of this disorder. [References: 33]

Title

Radiation-activated DNA-binding protein constitutively present in ataxia telangiectasia nuclei.

Source

Journal of Biological Chemistry. 268(30):22450-5, 1993 Oct 25.

Abstract

We have recently described the appearance of a specific DNA-binding protein in nuclei from human cells exposed to ionizing radiation which was not detected in nuclear extracts from unperturbed cells (Singh, S. P., and Lavin, M. F. (1990) Mol. Cell. Biol. 10, 5279-5285). We report here a similar activity which is constitutively present in nuclei of both unirradiated and irradiated cells from patients with the human genetic disorder ataxia telangiectasia (A-T). Activity was present in unirradiated nuclear extracts from 3 A-T cell lines of different complementation groups, but was not detected or was present only at a low level in 4 controls. Active protein was detected in the cytoplasm of both cell types. Exposure to ionizing radiation did not change the amount of DNA binding

activity in A-T nuclei but led to an increase in nuclei from 4 control cell lines. Purification of the binding activities from A-T nuclei and control cytoplasm was carried out by affinity chromatography, as described previously for control extracts (Teale, B., Singh, S. P., Khanna, K. K., Findik, D., and Lavin, M. F. (1992) J. Biol. Chem. 267, 10295-10301). Southwestern analysis and UV cross-linking confirmed the presence of a major DNA-binding species at 70 kDa in both cases with a minor binding activity at 47 kDa also evident. It was not possible to distinguish between the binding activities from A-T and control cells under different conditions, and phosphorylation was required for binding activity in both cases. Footprint analysis revealed that the same sequence was being recognized by the control and A-T proteins. The constitutive presence of a specific radiation-responsive DNA-binding protein in A-T cells may be indicative of a continuous state of stress in these cells.

Title

Delayed chromosomal instability induced by DNA damage.

Source

Molecular & Cellular Biology. 13(11):6667-77, 1993 Nov.

Abstract

DNA damage induced by ionizing radiation can result in gene mutation, gene amplification, chromosome rearrangements, cellular transformation, and cell death. Although many of these changes may be induced directly by the radiation, there is accumulating evidence for delayed genomic instability following X-ray exposure. We have investigated this phenomenon by studying delayed chromosomal instability in a hamster-human hybrid cell line by means of fluorescence in situ hybridization. We examined populations of metaphase cells several generations after expanding single-cell colonies that had survived 5 or 10 Gy of X rays. Delayed chromosomal instability, manifested as multiple rearrangements of human chromosome 4 in a background of hamster chromosomes, was observed in 29% of colonies surviving 5 Gy and in 62% of colonies surviving 10 Gy. A correlation of delayed chromosomal instability with delayed reproductive cell death, manifested as reduced plating efficiency in surviving clones, suggests a role for chromosome rearrangements in cytotoxicity. There were small differences in chromosome destabilization and plating efficiencies between cells irradiated with 5 or 10 Gy of X rays after a previous exposure to 10 Gy and cells irradiated only once. Cell clones showing delayed chromosomal instability had normal frequencies of sister chromatid exchange formation, indicating that at this cytogenetic endpoint the chromosomal instability was not apparent. The types of chromosomal rearrangements observed suggest that chromosome fusion, followed by bridge breakage and refusion, contributes to the observed delayed chromosomal instability.

Title

Reactive oxygen intermediates activate NF-kappa B in a tyrosine kinase-dependent mechanism and in combination with vanadate activate the p56lck and p59fyn tyrosine kinases in human lymphocytes.

Source

Blood. 82(4):1212-20, 1993 Aug 15.

Abstract

We have previously observed that ionizing radiation induces tyrosine phosphorylation in human B-lymphocyte precursors by stimulation of unidentified tyrosine kinases and this phosphorylation is substantially augmented by vanadate. Ionizing radiation generates reactive oxygen intermediates (ROI). Because H2O2 is a potent ROI generator that readily crosses the plasma membrane, we used H2O2 to examine the effects of ROI on signal transduction. We now provide evidence that the tyrosine kinase inhibitor herbimycin A and the free radical scavenger N-acetyl-cysteine inhibit both radiation-induced and H2O2-induced activation of NF-kappa B, indicating that activation triggered by ROI is dependent on tyrosine kinase activity. H2O2 was found to stimulate Ins-1,4,5-P3 production in a tyrosine kinase-dependent manner and to induce calcium signals that were greatly augmented by vanadate. The synergistic induction of tyrosine phosphorylation by H2O2 plus vanadate included physiologically relevant proteins such as PLC gamma 1. Although treatment of cells with H2O2 alone did not affect the activity of src family kinases, treatment with H2O2 plus vanadate led to activation of the p56lck and p59fyn tyrosine kinases. The combined inhibition of phosphatases and activation of kinases provides a potent mechanism for the synergistic effects of H2O2 plus vanadate. Induction of tyrosine phosphorylation by ROI may thus lead to many of the pleiotropic effects of ROI in lymphoid cells, including downstream activation of PLC gamma 1 and NF-kappa B.

Title

Flow cytometric analysis of lymphocyte surface markers following a 1-Gy dose of gamma radiation.

Source

Aviation Space & Environmental Medicine. 64(6):528-33, 1993 Jun.

Abstract

Flow cytometric analysis of lymphocytes labeled with monoclonal antibodies was undertaken in order to compare the mean fluorescent intensity of several surface membrane antigens (markers) from irradiated and

nonirradiated blood samples. Whole blood subjected to a 1-Gy (100-rad) dose of 1.25 MeV gamma radiation from a ^{60}Co radioisotope source was compared with nonirradiated blood drawn simultaneously from the same healthy subject. Twenty runs were performed in which the following T and B lymphocyte and natural killer surface markers were analyzed: CD2, CD3, 13, CD4, CD29, CD45RA, CD8, CD56, and CD19. The data demonstrate a radiation-induced decrement in the mean fluorescent intensity of the high molecular weight markers CD45RA and CD56 (decrement is -3.3% and -7.2%, respectively). The statistical validity of these values was confirmed using paired t-tests, which yielded p values of $p < 0.02$ (CD45RA) and $p < 0.01$ (CD56). The fluorescent intensity is proportional to the number of intact binding sites on the lymphocyte surface and the observed decrement directly infers that damage to some sites occurred. These results illustrate a measurable effect on the lymphocyte membrane at a radiation dose at which many lymphocytes will survive, yet may be immunologically altered. This study may have important implications for personnel exposed to ionizing radiation, such as astronauts on long duration missions and radiation workers involved in accidental exposures.

Title

Leukemia, lymphoma, and multiple myeloma after pelvic radiotherapy for benign disease.

Source

Radiation Research. 135(1):108-24, 1993 Jul.

Abstract

The relationship between exposure to sparsely ionizing radiation and mortality due to cancers of hematopoietic and lymphopoietic tissues was studied among 12,955 women treated for benign gynecological disorders at any of 17 hospitals in New England or New York State and followed for an average of 25 years; 9770 women were treated by radiation (intracavitary ^{226}Ra , external-beam X rays), while 3185 were treated by other methods, including curettage, surgery, and hormones. The average age at treatment was 46.5 years, and the mean dose to active bone marrow among irradiated women was 119 cGy. Forty deaths due to acute, myelocytic, or monocytic leukemia were observed among irradiated women. This number was 70% higher than expected based on U.S. mortality rates [standardized mortality ratio (SMR) = 1.7; 90% confidence interval (CI) 1.3-2.3]. A deficit was recorded among nonirradiated women, based on three observed deaths (SMR = 0.5; 90% CI 0.1-1.2). A well-defined gradient in the SMR with dose among exposed women was not detected. The SMR was highest within 5 years after irradiation but remained elevated even after 30 years. The temporal pattern differed by subtype of leukemia: excess mortality due to chronic

myelocytic leukemia occurred almost exclusively within the first 15 years, whereas the SMR for acute leukemia, though also elevated, varied little over time. Cancers of lymphoreticular tissue occurred more often than expected based on U.S. mortality rates, but not appreciably differently for irradiated and nonirradiated women. There was little or no evidence of effects attributable to radiotherapy for chronic lymphocytic leukemia [relative risk (RR) = 1.1; 90% CI 0.5-3.0], Hodgkin's disease (RR = 0.9; 90% CI 0.3-3.2), non-Hodgkin's lymphoma (RR = 0.9; 90% CI 0.6-1.6), or multiple myeloma (RR = 0.6; 90% CI 0.3-1.4). These results corroborate previous findings indicating that acute and myelocytic leukemias are the most prominent malignancies after exposure to sparsely ionizing radiation, occurring in excess shortly after irradiation, and that lymphomas are either not caused by radiation or are induced only rarely.

Title

DNA double-strand break rejoining deficiency in TK6 and other human B-lymphoblast cell lines.

Source

Radiation Research. 134(3):307-15, 1993 Jun.

Abstract

TK6, WI-L2, SB and three other B-lymphoblast lines were deficient in the rejoining of DNA double-strand breaks (DSBs) induced by ionizing radiation. Cells of these cell lines rejoin less than 50% of the breaks in 60 min after exposure, as assayed by filter elution at pH 9.6. The deficiency in TK6 cells was confirmed using the comet assay. IN TK6 cells the percentage of DSB rejoining did not vary markedly with dose and was similar for G1, S, and G2 + M-phase cells. Two B-lymphocyte lines (Raji and GM0606), three T-lymphoblast lines (MOLT-4, Jurkat, and CCRF-HSB-2), HL-60 promyelocytes, and GM3440 human skin fibroblasts rejoined more than 50% of the DSBs in this period after exposure. Radiation sensitivity in terms of cell survival was measured in those cells forming colonies. Of the cell lines tested, those that were deficient in DSB rejoining were radiation-sensitive (TK6 and WI-L2: $D_0 = 0.64$ Gy). However, not all lines that were proficient in DSB rejoining were radiation-resistant, since Jurkat and GM0606 cells were relatively radiation-sensitive ($D_0 = 0.63$ - 0.73 Gy). TK6 and WI-L2 cells were more sensitive to bleomycin ($D_0 = 8$ - 9 micrograms/ml) than were HL-60 and Raji cells ($D_0 = 40$ - 54 micrograms/ml). No relationship of DSB rejoining to V(D)J recombinase activity was observed, since no mRNA hybridizing to the cDNA probes for RAG-1 or RAG-2 was detected in any of the cell lines tested.

Title

Ratios of radiation-produced chromosome aberrations as indicators of large-scale DNA geometry during interphase.

Source

Radiation Research. 133(3):345-50, 1993 Mar.

Abstract

Chromosome aberrations produced by ionizing radiation are assumed to develop from DNA double-strand breaks (DSBs) which interact pairwise. Stable chromosome aberrations that exemplify inter- and intra-chromosomal exchanges are, respectively, translocations and pericentric inversions. By comparing the number of these for each chromosome one can infer results on the randomness of DSB induction or exchange formation and on large-scale chromosome geometry. We analyze frequencies of translocations and pericentric inversions in lymphocytes from 38 A-bomb survivors, using G-banding. A total of 636 translocations and 102 pericentric inversions were found. The 636/102 ratio of translocations to pericentric inversions is approximately 14 times smaller than predicted by a random model, in general agreement with earlier results and results on the ratio of dicentrics to centric rings for in vitro irradiation. Presumably the excess of intra-chromosomal exchanges is due to a spatial proximity effect, implying a localization of chromosomes within the cell nucleus during and shortly after irradiation. The distribution of the pericentric inversions among different chromosomes indicates this proximity effect is roughly the same for all chromosomes, regardless of DNA content; i.e., the ratio of pericentric inversions for two different chromosomes approximately equals the ratio given by a model which takes into account chromosome lengths and centromere locations but otherwise assumes randomness. Possible exceptions are chromosomes 7 and 12, which show some excess of pericentric inversions. The percentage of translocations involving each chromosome corresponds roughly to the percentage expected assuming randomness, except that for chromosome 1 there is a significant excess.

Title

Using three-color chromosome painting to test chromosome aberration models.

Source

Proceedings of the National Academy of Sciences of the United States of America. 90(4):1484-7, 1993 Feb 15.

Abstract

Ionizing radiation induces DNA double-strand breaks (DSB), which interact pairwise to produce chromosome aberrations. There have long been two main

competing theories of such pairwise DSB-DSB interactions. The "classical" theory asserts that an unrepaired DSB makes two ends that separate within the cell nucleus, with each end subsequently able to join any similar (nontelomeric) end. The "exchange" theory asserts that at a DSB the chromatin does not separate completely; rather the DSB ends remain associated until repair, or an illegitimate recombination involving another DSB, occurs. The DSB-DSB interaction mechanism was tested by using three-color fluorescence in situ hybridization to paint chromosomes and observe "three-color triplets": three broken and misrejoined chromosomes having cyclically permuted colors. We observed 18 "three-color triplets" in 2000 cells after 2.25 Gy of gamma-irradiation. On the exchange model in its standard form such three-color triplets cannot occur, so this model is inconsistent with the observations. On the classical model, formalized as a discrete time Markov chain embedded at the transitions of a continuous time Markov chain, the frequency of occurrence of three-color triplets can be computed by Monte Carlo simulations. The number of three-color triplets predicted mathematically by the classical model was found to be slightly larger than the observed number. Thus our data, together with our computer simulations, exclude the standard form of the exchange model but are compatible with the classical model. The results are also compatible with other, more complicated models.

Title

A role for manganese superoxide dismutase in radioprotection of hematopoietic stem cells by interleukin-1.

Source

Blood. 81(3):639-46, 1993 Feb 1.

Abstract

Pretreatment with interleukin-1 (IL-1) has been shown to protect mice from the myelotoxicity associated with irradiation via a mechanism potentially mediated through the induction of the antioxidant enzyme manganese superoxide dismutase (MnSOD). In this study, we have compared the ability of IL-1 to induce MnSOD mRNA in murine bone marrow cells and human cell lines with its ability to protect these cells against the damaging effects of ionizing radiation. Bone marrow cells obtained from mice 6 hours after a single injection of IL-1 demonstrate a dose-dependent increase in the expression of MnSOD RNA. In this same study, IL-1 was also shown to be radioprotective when given to mice 20 hours before lethal irradiation. Similarly, in vitro treatment with IL-1 of bone marrow cells isolated from 5-fluorouracil-treated mice results in elevated levels of MnSOD RNA. Pretreatment with IL-1 also protected bone marrow long-term culture-initiating cells capable of reconstituting irradiated stromal cultures from an irradiation insult. Furthermore, IL-1-treated human bone marrow cells display both elevated MnSOD RNA and protein levels when compared with media controls. The human A375 melanoma, A549

adenocarcinoma, and factor-dependent TF-1 leukemic cell lines demonstrate low basal MnSOD RNA levels that increase following treatment with IL-1. For the A375 cells, this correlates with increased MnSOD protein expression and radioprotection by IL-1 using a colony assay. In contrast, the chronic myelogenous leukemic cell line, K562, displays a high basal MnSOD RNA level, and this RNA expression is not further increased by IL-1 treatment. In addition, these cells are comparatively radioresistant and are not further protected by IL-1 treatment. Finally, the Mo-7 cell line displays a low basal level of MnSOD RNA that correlates with a high sensitivity to irradiation and IL-1 pretreatment has no effect on MnSOD RNA levels. Our results indicate that increased radioprotection by IL-1 correlates with the induction of the antioxidant enzyme MnSOD and this induction may be an important factor in IL-1 radioprotection.

Title

Role of tyrosine phosphorylation in radiation-induced activation of c-jun protooncogene in human lymphohematopoietic precursor cells.

Source

Cancer Research. 53(3):447-51, 1993 Feb 1.

Abstract

We examined the effects of ionizing radiation on c-jun expression in human lymphohematopoietic precursors. Radiation exposure increased the level of c-jun transcripts in a dose- and time-dependent manner, providing direct evidence that ionizing radiation can activate c-jun protooncogene in human lymphohematopoietic precursors. Notable gamma-rays failed to induce c-jun expression in cells pretreated with herbimycin, and the use of cycloheximide did not overcome the inhibitory effects of herbimycin. The lack of c-jun signal in herbimycin-treated cells was not due to nonspecific damage to the distal protein kinase C signaling pathway. Thus, protein tyrosine kinase activation precedes and perhaps mandates radiation-induced activation of c-jun protooncogene expression in human lymphohematopoietic precursors.

Title

Tyrosine phosphorylation is a mandatory proximal step in radiation-induced activation of the protein kinase C signaling pathway in human B-lymphocyte precursors [published erratum appears in Proc Natl Acad Sci U S A 1993 Apr

15;90(8):3775].

Source

Proceedings of the National Academy of Sciences of the United States of America. 90(1):252-6, 1993 Jan 1.

Abstract

Ionizing radiation triggers a signal in human B-lymphocyte precursors that is intimately linked to an active protein-tyrosine kinase regulatory pathway. We show that in B-lymphocyte precursors, irradiation with gamma-rays leads to (i) stimulation of phosphatidylinositol turnover; (ii) downstream activation by covalent modification of multiple serine-specific protein kinases, including protein kinase C; and (iii) activation of nuclear factor kappa B. All of the radiation-induced signals were effectively prevented by the protein-tyrosine kinase inhibitors genistein and herbimycin A. Thus, tyrosine phosphorylation is an important and perhaps mandatory proximal step in the activation of the protein kinase C signaling cascade in human B-lymphocyte precursors. Our report expands current knowledge of the radiation-induced signaling cascade by clarifying the chronological sequence of biochemical events that follow irradiation.

Title

Anticlastogenic effects of a polyvitamin product, 'Pharmavit', on gamma-ray induction of somatic and germ cell chromosome aberrations in the mouse.

Source

Mutation Research. 269(2):251-8, 1992 Oct.

Abstract

The polyvitamin product 'Pharmavit' (Pv), comprising vitamins A, D2, B1, B2, B6, C, E, nicotinamide, and calcium pantothenate, was tested for anticlastogenic properties against gamma-rays in mice. Pretreatment with Pv consisted of daily administration by gavage for 30 days at dose levels corresponding to clinical recommendations for an adult human, as recalculated in terms of mg/kg. Findings indicated a reduction of chromosome aberrations in bone marrow cells from mice exposed to 3.0 Gy ¹³⁷Cs gamma-rays; the reduction concerned predominantly fragments of the chromatid type. Furthermore, a reduction factor of 1.6 was obtained for the frequency of reciprocal translocations induced by spermatogonial irradiation in mice exposed to 4.0 Gy gamma-rays. Pretreatment with vitamin C alone, at the dose present in Pv, proved nearly ineffective in protecting from chromosome aberrations in bone marrow cells. Pharmavit is believed to be a promising agent for application to human populations exposed to the carcinogenic and genetic hazards of ionizing radiation.

Title

Lack of adaptive response to low doses of ionizing radiation in human lymphocytes from five different donors.

Source

Mutation Research. 283(2):137-44, 1992 Oct.

Abstract

Various investigators reported a reduced yield of chromosome and chromatid aberrations in short-term cultures of human lymphocytes if a 'challenge' exposure to ionizing radiation was preceded by an 'adaptive' exposure. In order to examine the cell cycle dependence of the 'adaptive response', chromosome and chromatid aberration yields were estimated after challenge doses in the G1, S or G2 phase of lymphocytes which had been adapted in the early G1 phase. On testing two donors no protective adaptive response was found. Blood samples of four donors were tested for their capability to evoke the adaptive response in a standard experiment with the adaptive dose in the S phase and the challenge dose in the G2 phase. A synergistic response occurred in one out of two similar experiments performed with the same blood sample. The three other blood samples tested did not respond. Apparently these data indicate a high frequency of human lymphocyte cultures that do not display an adaptive response.

Title

Repair of DNA damage induced by oxygen radicals in human non-proliferating and proliferating lymphocytes.

Source

Mutation Research. 274(2):103-10, 1992 Aug.

Abstract

Repair of DNA lesions induced by oxygen radicals, generated by xanthine/xanthine oxidase (X/XO), was studied in human peripheral blood lymphocytes and in PHA-stimulated proliferating lymphocytes from 4 healthy subjects. The lesions included DNA-strand breaks (SSB) and other lesions that are converted to SSB under alkaline conditions. The frequencies of SSB were estimated by fluorometric analysis of DNA unwinding. Maximum production of SSB occurred within 10 min of incubation with X/XO at 22 degrees C; with 0.5 mM or higher concentrations of xanthine; and with 0.1-0.5 units/ml of xanthine oxidase. Proliferating lymphocytes repaired X/XO-induced SSB about 4 times more rapidly than lymphocytes. Lymphocytes repaired X/XO-induced SSB more slowly than SSB caused by gamma-radiation. These findings are consistent with the evidence that a number of DNA-repair enzymes have greater activity in proliferating cells than in resting cells. These findings also support the view that there are differences between the DNA damage due to oxygen radicals and that due to ionizing radiation.

Title

Quantitative detection of DNA damage in cells after exposure to ionizing radiation by means of an improved immunochemical assay.

Source

Mutation Research. 274(1):19-27, 1992 Jun.

Abstract

A simple, sensitive and fast immunochemical method has been developed to quantify the amount of DNA damage in cells of human blood after in vitro exposure to ionizing radiation. The technique is based on the enhancement of the radiation-induced single-strandedness, which occurs in DNA regions flanking strand breaks, by a controlled further unwinding of the DNA in an alkaline solution. Subsequently, the DNA is attached to the wall of polystyrene cups by passive adsorption. DNA damage is then quantified by determining the extent of single-strandedness with a monoclonal antibody, D1B, directed against single-stranded DNA. D1B binding is assayed with a 'second' antibody, labelled with either an enzyme or europium. The latter gives slightly more reproducible results. No radioactive labelling of DNA is required and the assay takes only 3.5 h after the collection of blood. Damage can be detected after doses as low as 0.5 Gy. The potential broader application of the method is discussed.

Title

Cytogenetic and survival adaptive responses in G1 phase human lymphocytes.

Source

Mutation Research. 265(2):273-81, 1992 Feb.

Abstract

Human lymphocytes from six donors were treated with 5 cGy of X-rays followed by 200 or 400 cGy in the first G1 phase after PHA stimulation, and assayed for cytogenetic aberrations and cell survival. Four donors showed cytogenetic adaptive responses with 400 cGy, and one with both 200 cGy and 400 cGy. Both exchanges and deletions were reduced, indicating that the cytogenetic adaptive response acts by restitution of chromosome breaks. Good correlations were found between nonaberrant cells and survival, although the former were often higher than the later, especially with the 400 cGy dose. In four of six donors, 5 cGy alone had significant effects on cell survival; however, this was independent of the 5 cGy effect on high-dose-induced responses. Two donors had survival adaptive responses with 5 + 200 cGy, while none were found with the 5 + 400 cGy

treatment. The comparisons between the cytogenetic and survival responses suggests that a survival adaptive response will only be seen with a sufficient increase in nonaberrant cells. To date, adaptive responses to ionizing radiation have been reported to occur in G0, G1 and late S/early G2 human lymphocytes.

Title

Inter-individual differences in radiation response shown by an in vitro micronucleus assay: effects of 3-aminobenzamide on X-ray treatment.

Source

International Journal of Radiation Biology. 62(6):687-94, 1992 Dec.

Abstract

Among the methods of biological dosimetry of ionizing radiation, we propose the cytokinesis-block micronucleus assay for the measurement of the individual dose absorbed. The dose-response curve was determined for in vitro-irradiated lymphocytes from 25 individuals. The dose-response relationship, fitted by the linear-quadratic function, was $F(MN) = 0.015 (+/- 0.0016) + 0.043 (+/- 0.0075).D + 0.083 (+/- 0.0045).D^2$. Our results are compared with those of other authors. 3-aminobenzamide (3AB) combined with X-rays were used to evaluate the micronucleus dose-response relationship in blood from 14 individuals. While it is known that 3AB inhibits poly(ADP-ribose) polymerase activity in vitro, we demonstrate that it also increases the X-ray-induced micronucleus yields. The resulting dose-response relationship varies from subject to subject. The possibility of using this approach to identify the individual radiosensitivity level is discussed.

Title

Mutations caused by gamma-radiation-induced double-strand breaks in a shuttle plasmid replicated in human lymphoblasts.

Source

International Journal of Radiation Biology. 62(5):555-62, 1992 Nov.

Abstract

The mutagenicity of open-circular DNA (containing base damage and single-strand breaks) and linear DNA (containing base damage, single-strand breaks, and one double-strand break) produced in vitro by gamma-irradiation of shuttle vector pZ189, was analysed after the plasmid's repair and replication in the human lymphoblast line, GM606. By comparing the survival, mutation frequency, and types of mutations in

descendants from the two DNA forms, the effects of the double-strand break were determined. The percentage of viable plasmids from linear DNA was two-fold lower than that from open-circular DNA, 7.8 versus 14.0 (compared with unirradiated, control DNA). The mutation frequency in progenies of the open-circular plasmid was $4.2 \pm 1.7 \times 10^{-3}$, compared with $7.8 \pm 0.1 \times 10^{-3}$ in progenies of the linear DNA, again, nearly a two-fold difference. Approximately 59% of the mutations from the linear DNA were deletions and 34% were base substitutions. In contrast, only 13% of mutations from open-circular DNA were deletions, but 87% were base substitutions. All recoverable deletions were small, ranging from 1 to 205 base pairs, and the majority contained direct repeats at the deletion junctions, indicating non-homologous recombinations. Thus, mutations found among descendants from the linear and open-circular DNAs were qualitatively similar but quantitatively different. The data suggests that producing one double-strand break in DNA by ionizing radiation causes a two-fold increase in both lethality and mutation frequency.

[A possible role of neuroimmunoendocrine interactions and development of post-irradiation pathology]. [Russian]

Source

Radiobiologiya. 32(3):435-40, 1992 May-Jun.

Abstract

On the basis of the literature a postulate is proposed that the immune system contributes to regulating the intensity and direction of endocrine and nervous system functions in normal conditions and after the effect of ionizing radiation. The role of neuroimmunoendocrine interactions and their impairment in the realization of stochastic and nonstochastic sequelae of irradiation at various levels of radiation affecting the organism under normal conditions and in a combination with other unfavourable factors.

[Study of possible influence of mixed lymphocyte reaction on experimental models used in biological dosimetry]. [French]

Source

Comptes Rendus des Seances de la Societe de Biologie et de Ses Filiales. 186(3):226-30, 1992.

Abstract

The study aimed to investigate whether "mixed lymphocyte reactions" could interfere with the results of experiments in which irradiated blood from

one person is mixed with non-irradiated blood from another. This experimental model had been designed to simulate, in vitro, non-homogeneous in vivo exposure such as could occur after accidents with ionizing radiation. The results show that the experimental models gives valid results for donors with related blood characteristics.

[The immune status of patients with neurocirculatory dystonia subjected to ionizing radiation exposure during the cleanup of the accident at the Chernobyl Atomic Electric Power Station]. [Russian]

Source

Vrachebnoe Delo. (5):20-3, 1992 May.

Abstract

The immune state of 77 cleanup workers of Chernobyl power plant accident suffering from vegetative dystonia was studied. The group of comparison consisted of 10 vegetative dystonia patients, who were not subjected to the ionizing radiation influence. The workers showed no specific changes of immunity, but immune state disturbances among them were more frequent and more pronounced than in ordinary vegetative dystonia patients.

Title

Radiation-induced DNA single-strand breaks in freshly isolated human leukocytes.

Source

Radiation Research. 132(2):200-6, 1992 Nov.

Abstract

Single-strand breaks are a major form of DNA damage caused by ionizing radiation, and measurement of strand breaks has long been used as an index of overall cellular DNA damage. Most assays for DNA single-strand breaks in cells rely on measuring fractionated DNA samples following alkali denaturation. Quantification is usually achieved by prelabeling cells with radioactive DNA precursors; however, this is not possible in the situation of nondividing cells or freshly isolated tissue. It has previously been demonstrated that the alkali unwinding assay of DNA strand breaks can be quantified by blotting the recovered DNA on nylon membranes and hybridizing with radiolabeled sequence-specific probes. We report here improvements to the technique, which include hot alkali denaturation of DNA samples prior to blotting and the use of carrier DNA that is non-complementary to the radiolabeled probe. Our method allows both single- and double-stranded DNA to be quantified with the same efficiency, thereby improving the sensitivity and reproducibility of the assay, and

allows calibration for determination of absolute levels of DNA strand breaks in cells. We also used this method to assay radiation-induced DNA strand breaks in freshly isolated human leukocytes and found them to have a strand break induction rate of 1815 strand breaks/cell/Gy.

Title

Retinoid protection against x-ray-induced chromatid damage in human peripheral blood lymphocytes.

Source

Journal of Clinical Investigation. 90(5):2069-74, 1992 Nov.

Abstract

Oral administration of isotretinoin (13-cis retinoic acid) was shown previously (Kraemer, K. H., J. J. DiGiovanna, A. N. Moshell, R. E. Tarone, and G. L. Peck. 1988. N. Engl. J. Med. 318:1633-1637) to reduce the frequency of skin cancers in xeroderma pigmentosum (XP) patients. The mechanism of protection was unclear. In the present study, x-ray-induced chromatid damage in PHA-stimulated blood lymphocytes from five XP patients receiving isotretinoin was approximately half that in blood samples from the same patients before or subsequent to treatment. The x-ray-induced chromatid damage in blood lymphocytes from a normal control was reduced significantly by cocultivation with blood or plasma from an XP patient receiving isotretinoin or by addition of 10^{-6} M isotretinoin to cultures 1 h before x-irradiation. A similar reduction in x-ray-induced chromatid damage was reported previously by adding to the culture medium, mannitol, a scavenger of the free hydroxyl radical, or catalase, which decomposes hydrogen peroxide; both of these products are generated during ionizing radiation. The present observations suggest that isotretinoin acts as a scavenger of such radiation products, thereby providing protection against x-ray-induced chromatid damage.

Title

Ionizing radiation stimulates unidentified tyrosine-specific protein kinases in human B-lymphocyte precursors, triggering apoptosis and clonogenic cell death.

Source

Proceedings of the National Academy of Sciences of the United States of America. 89(19):9005-9, 1992 Oct 1.

Abstract

Very little is known regarding the effects of ionizing radiation on cytoplasmic signal transduction pathways. Here, we show that ionizing radiation induces enhanced tyrosine phosphorylation of multiple substrates in human B-lymphocyte precursors. This response to ionizing radiation was also observed in cells pretreated with vanadate, a potent protein-tyrosine-phosphatase (PTPase) inhibitor, and phosphotyrosyl [Val5]angiotensin II phosphatase assays showed no decreased PTPase activity in irradiated cells. Thus, enhanced tyrosine phosphorylation in irradiated B-lymphocyte precursors is not triggered by inhibition of total cellular PTPase activity. Immune-complex kinase assays using anti-phosphotyrosine antibodies demonstrated enhanced protein-tyrosine kinase (PTK) activity in the immunoprecipitates from irradiated cells, and the PTK inhibitors genistein and herbimycin effectively prevented radiation-induced tyrosine phosphorylation. Immune-complex kinase assays on irradiated and unirradiated B-lymphocyte precursors using antibodies prepared against unique amino acid sequences of p59fyn, p56/p53lyn, p55blk, and p56lck demonstrated that these Src-family tyrosine kinases were not the primary PTKs responsible for enhanced tyrosine kinase activity in the anti-phosphotyrosine antibody immunoprecipitates or for enhanced tyrosine phosphorylation of multiple substrates. Thus, our findings favor the hypothesis that ionizing radiation induces enhanced tyrosine phosphorylation in B-lymphocyte precursors by stimulation of as yet unidentified PTKs. Tyrosine phosphorylation appears to be an important proximal step in radiation-induced apoptosis and clonogenic cell death because inhibition of PTK prevents DNA fragmentation and loss of clonogenicity of irradiated B-lymphocyte precursors. Since PTKs play myriad roles in the regulation of cell function and proliferation, the activation of a PTK cascade, as detailed in this report, may explain some of the pleiotropic effects of ionizing radiation on cellular functions of B-lymphocytes and their precursors.

Title

The ratio of dicentrics to centric rings produced in human lymphocytes by acute low-LET radiation.

Source

Radiation Research. 129(3):304-8, 1992 Mar.

Abstract

Chromosome aberrations produced by ionizing radiation are assumed to develop from DNA double-strand breaks (DSBs) which interact pairwise, in an exchange event. Dicentrics and centric rings are aberrations that exemplify inter- and intrachromosomal exchanges, respectively. We show from a survey of published data that for acute low-LET irradiation of resting human lymphocytes the observed ratio of dicentrics to centric rings is approximately five times smaller than predicted by a pairwise

interaction model which assumes complete randomness. Such a low ratio can be interpreted as evidence for a proximity effect, favoring exchanges of an intrachromosomal type. That is, since DSBs induced close together have an above-average chance of pairwise interaction, the observed excess of centric rings indicates that at the time of irradiation there is some degree of spatial confinement for the two arms of a single chromosome. Assuming the excess of centric rings is indeed due to proximity effects, the data are used to estimate that the volume of a domain, within which any one lymphocyte chromosome is localized at one instant during the G0/G1 phase, is at most approximately 20% of the nuclear volume.

Title

Ionizing radiation increases TNF/cachectin production by human peripheral blood mononuclear cells in vitro.

Source

International Journal of Hematology. 55(2):127-30, 1992 Apr.

Abstract

Human peripheral blood mononuclear cells (PBMC) and monocytes produce a large amount of tumor necrosis factor/cachectin (TNF) in vitro. Our data suggest that X-irradiation can increase TNF production by these cells. After 900 cGy irradiation there were 7-fold (24 h incubation) and 2.3-fold (48 h incubation) increases of TNF production by stimulated PBMC. The irradiation also increased TNF production by both stimulated and unstimulated human monocytes. These findings suggest that TNF overproduction can play an important role in the pathogenesis of radiation disease.

Title

Automated detection of radiation-induced chromosome aberrations following fluorescence in situ hybridization.

Source

Journal of Radiation Research. 33 Suppl:189-205, 1992 Mar.

Abstract

The cytogenetic detection of rare chromosome aberrations induced by ionizing radiation requires the evaluation of large numbers of cells. In this report, an image analysis program based on thresholding of grey level histograms is described for a rapid automated detection of chromosome translocations in metaphase spreads from human lymphocytes following irradiation and chromosome in situ suppression (CISS) fluorescence in situ hybridization (FISH). To classify a metaphase spread as "normal",

"aberrant", or "excluded", a minimum medium time of less than two seconds was required on a general purpose Personal Computer. Using appropriately stained specimen, for the false classification rate an upper limit of about 10% was estimated. The upper limit for the rate of "excluded" cells was estimated to be about 11% (99% confidence ranges). FISH-procedures allow to score chromosome aberrations also in the interphase nucleus. To apply simple threshold algorithms for segmentation of the FISH-stained nuclear areas, it is required that the grey level contrast is sufficiently high. The preliminary results presented here on the image analysis of human lymphocyte nuclei suggest the feasibility of such an approach.

Title

[Concept of the effect of low doses of ionizing radiation on cells and its possible use in the interpretation of medical-biological consequences].

[Review] [Russian]

Source

Radiobiologiya. 32(3):382-400, 1992 May-Jun.

Abstract

A concept is proposed where the events induced by low doses of ionizing radiation with low linear energy transfer have different script than those induced by high doses. Its essence consist in the existence of a small fraction (subpopulation) in clonal heterogeneous population whose cells are determined for a specific programmed response induced by a number of action that are potentially able (at high doses) to decrease the survival of the given population. The function of the postulated cell is a deliberate sacrifice necessary for formation of evolutionary reserve. A mechanism of this response is based on an autogeneration of wide-scale genome rearrangements in cells and is not connected with direct influence of genetically hazardous agents on DNA. This leads to arising of a number of genetic variants (evolutionary reserve cells). Selection among them enhancing survival of the population may in the same time lead to harmful consequences for the organism (if there are malfunctions of the immune system). Medical-biological consequences of the effect of low doses are associated with the appearance of such clones and biologically active products secreted from the exposed cells. Mechanisms responsible for the above phenomena are discussed. [References: 95]

A means of retaining chromosome damage in irradiated human lymphocytes.

Source

Health Physics. 63(3):349-51, 1992 Sep.

Abstract

The method of premature chromosome condensation has been used to determine the damage induced by ionizing radiation to chromosomes in G1 human lymphocytes. The method has also demonstrated the repair of such damage with time following exposure. This study shows how storage at a cold temperature can be used to retain this damage for further biodosimetric study.

Title

Mutation spectrum in gamma-irradiated shuttle vector replicated in ataxia-telangiectasia lymphoblasts.

Source

Radiation Research. 130(3):331-9, 1992 Jun.

Abstract

Cells from ataxia-telangiectasia (AT) patients are hypersensitive to the lethal effects of ionizing radiation. To assess radiation mutagenesis in these cells, the SV40-based shuttle vector, pZ189, was used to analyze gamma-ray-induced mutations following the plasmid's replication in AT lymphoblasts. Progenies from the AT line GM2783 exposed to 50 Gy showed a mutation frequency of 7.6×10^{-3} , 63-fold over background; surviving plasmids were 3.4% of control. Both values were essentially the same as those of irradiated plasmids replicated in a normal lymphoblast line, GM606. In addition, pZ189 exposed to 25 Gy of gamma radiation and replicated in another normal lymphoblast line and in cells of two additional AT lymphoblast lines showed similar mutation frequencies and percentages of surviving plasmids. Qualitative comparison of plasmid mutations from AT and normal cells showed no significant differences, indicating that the damaged DNA was repaired with similar fidelity in AT and normal cells. These studies suggest that there is no correlation between the enhanced sensitivity of AT cells to killing by ionizing radiation and gamma-radiation-induced mutagenesis of plasmid DNA processed in these cells.

Title

Evolution of DNA damage in irradiated cells.

Source

Journal of Mathematical Biology. 30(5):493-511, 1992.

Abstract

Ionizing radiation damage to a mammalian genome is modeled using

continuous time Markov chains. Models are given for the initial infliction of DNA double strand breaks by radiation and for the enzymatic processing of this initial damage. Damage processing pathways include DNA double strand break repair and chromosome exchanges. Linear, saturable, or inducible repair is considered, competing kinetically with pairwise interactions of the DNA double strand breaks. As endpoints, both chromosome aberrations and the inability of cells to form clones are analyzed. For the post-irradiation behavior, using the discrete time Markov chain embedded at transitions gives the ultimate distribution of damage more simply than does integrating the Kolmogorov forward equations. In a representative special case explicit expressions for the probability distribution of damage at large times are given in the form used for numerical computations and comparisons with experiments on human lymphocytes. A principle of branching ratios, that late assays can only measure appropriate ratios of repair and interaction functions, not the functions themselves, is derived and discussed.

Title

Idiopathic hemochromatosis and chromosomal damage.

Source

Human Heredity. 42(2):143-5, 1992.

Abstract

Spontaneous and radiation-induced chromosome damage in cultured lymphocytes was examined in a pilot study of 11 patients with idiopathic hemochromatosis and matched controls. Increased frequencies of chromosome breaks were found in the patients, both spontaneously and after exposure to ionizing radiation, but the differences between patients and controls were not statistically significant (p greater than 0.05) when individual data were analyzed. When pooled (group) data for patients and controls were compared, significant increases in spontaneous and radiation-induced chromosome breaks were found among the patients. The results suggest that iron overload may lead to chromosome damage in idiopathic hemochromatosis.

Title

Endogenous oxidative damage of deoxycytidine in DNA.

Source

Proceedings of the National Academy of Sciences of the United States of America. 89(8):3380-4, 1992 Apr 15.

Abstract

Three major oxidation products of 2'-deoxycytidine (dC)--5-hydroxy-2'-deoxycytidine (oh5dC), 5-hydroxy-2'-deoxyuridine (oh5dU), and 5,6-dihydroxy-5,6-dihydro-2'-deoxyuridine (dUg)--were analyzed from enzymatically hydrolyzed DNA with reversed-phase high-performance liquid chromatography coupled to electrochemical detection. oh5dC and oh5dU can be detected with high sensitivity (50 fmol) and selectivity (0-0.2 V) from hydrolyzed DNA. dUg is not electrochemically active but can be measured by dehydrating it into oh5dU. The quantities of oh5dC, dUg, and oh5dU in untreated commercial-grade calf thymus DNA are 10, 10, and 0.75 fmol/micrograms of DNA, respectively. These levels increased substantially when calf thymus DNA was exposed to ionizing radiation, H₂O₂ alone, H₂O₂ and combinations of Fe³⁺ or Cu²⁺ and ascorbate, near-UV light (365 nm), near-UV light in the presence of menadione, and OsO₄, indicating that oh5dC, oh5dU, and dUg are major oxidative DNA damage products. The steady-state levels of these products were determined from freshly extracted rat tissues and ranged from less than 0.5 fmol/micrograms of DNA for oh5dU to about 10 fmol/micrograms of DNA for oh5dC and dUg in liver and kidney and 22 fmol/micrograms of DNA for oh5dC in brain. The levels of oxo8dG were also determined and in general were somewhat lower than the levels of oh5dC. These findings reinforce the link between DNA damage induced by oxidative metabolism and spontaneous mutagenesis leading to cancer and aging.

Title

Different repair kinetics of radiation-induced DNA lesions in human and murine white blood cells.

Source

Carcinogenesis. 13(3):457-62, 1992 Mar.

Abstract

Exposure of cells to ionizing radiation gives rise to DNA damage, comprising strand breaks and base modifications. All these lesions may contribute to cell death, mutagenesis and/or carcinogenesis, but their relative contributions are likely to be different. It is important, therefore, to study the various damages with respect to their abundance and persistence. To detect radiation-induced DNA damage, the alkaline-elution technique was applied. In a flanking comparative study, a newly developed immunochemical assay was used. Mice were irradiated with X-rays (8 or 12 Gy) and killed at different time intervals after the irradiation. Total white blood cells and bone-marrow were isolated, and the different types of DNA damage determined. Murine blood and bone-marrow cells, as well as human blood, were irradiated in vitro and subsequently incubated at 37 degrees C for different time periods, followed by analysis of radiation-induced DNA damage. Also, white blood cells from leukemia patients receiving chemo- and radiotherapy (total-body irradiation) were investigated, to study the in vivo induction and repair of DNA lesions in

AB The occurrence of serious accidents in complex industrial systems such as at *Three* *Mile* *Island* and Bhopal has prompted development of new models of causation and investigation of disasters. These analytical models have potential relevance in anaesthesia. We therefore applied one of the previously described systems to the investigation of an anaesthetic accident. The model chosen describes two kinds of failures, both of which must be sought. The first group, active failures, consists of mistakes made by practitioners in the provision of care. The second group, latent failures, represents flaws in the administrative and productive system. The model emphasizes the search for latent failures and shows that prevention of active failures alone is insufficient to avoid further accidents if latent failures persist unchanged. These key features and the utility of this model are illustrated by application to a case of aspiration of gastric contents. While four active failures were recognized, an equal number of latent failures also became apparent. The identification of both types of failures permitted the

formulation of recommendations to avoid further occurrences. Thus this model of accident causation can provide a useful mechanism to investigate and possibly prevent anaesthetic accidents.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB BACKGROUND: In the light of a possible link between stress and cancer promotion or progression, and of previously reported distress in

residents near the *Three* *Mile* *Island* (TMI) nuclear power plant, we attempted to evaluate the impact of the March 1979 accident on community cancer rates. METHODS: Proximity of residence to the plant, which related to distress in previous studies, was taken as a possible indicator of accident stress; the postaccident pattern in cancer rates was examined in 69 "study tracts" within a *10-mile* radius of TMI, in relation to residential proximity. RESULTS: A modest association was found between postaccident cancer rates and proximity (OR = 1.4; 95% CI = 1.3, 1.6). After adjusting for a gradient in cancer risk prior to the accident, the odds ratio contrasting those closest to the plant with those living farther out was 1.2 (95% CI = 1.0, 1.4). A postaccident increase in cancer rates near the *Three* *Mile* *Island* plant was notable in 1982, persisted for another year, and then declined. Radiation emissions, as modeled mathematically, did not account for the observed increase. CONCLUSION: Interpretation in terms of accident stress is limited by the lack of an individual measure of stress and by uncertainty about whether stress has a biological effect on cancer in humans. An alternative mechanism for the cancer increase near the plant is through changes in care-seeking and diagnostic practice arising from postaccident concern. Author-abstract.

AN 91203110. 91000. AU Prince-Embury-S. Rooney-J-F. IN Department of Outpatient Psychiatry, Jersey Shore Medical Center. TI Life stage differences in resident coping with restart of the *Three* *Mile* *Island* nuclear generating facility. SO J-Soc-Psychol. 1990 Dec. 130(6). P 771-9. JT JOURNAL OF SOCIAL PSYCHOLOGY. PT JOURNAL-ARTICLE (ART). LG English (EN). AB A study of residents who remained in the vicinity of *Three* *Mile* *Island* (TMI) immediately following the restart of the nuclear generating plant revealed that older residents employed a more emotion-focused coping style in the face of this event than did younger residents. Coping style was, however, unrelated to the level of psychological symptoms for these older residents, whereas

demographic variables were related. Among younger residents, on the other hand, coping style was related to the level of psychological symptoms, whereas demographic variables were not. Among younger residents, emotion-focused coping was associated with more symptoms and problem-focused coping was associated with fewer symptoms, contradicting previous findings among TMI area residents.

JT HEALTH PSYCHOLOGY.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Discusses the nature of stress in the context of problems with its definition and sources of confusion regarding its usefulness and specificity. Stress can be defined as a negative emotional experience accompanied by predictable biochemical, physiological, and behavioral changes that are directed toward adaptation either by manipulating the situation to alter the stressor or by accommodating its effects. Chronic stress is more complex than most definitions suggest and is clearly not limited to situations in which stressors persist for long periods of time. Responses may habituate before a stressor disappears or may persist long beyond the physical presence of the stressor. This latter case, in which chronic stress and associated biobehavioral changes outlast their original cause, is considered in light of research at *Three* *Mile* *Island* and among Vietnam veterans. The role of intrusive images of the stressor or uncontrollable thoughts about it in maintaining stress is explored.

AB Five years after the *Three* *Mile* *Island* nuclear accident, the mental
health of women who had been pregnant and living within 10 *miles* of
Three *Mile* *Island* at the time of the accident was similar to that of
women from the same area who became pregnant after the accident.
Ratings of the development of the two groups of children when they
were 5 years old were also similar. However, women who were pregnant
during the crisis and had been "extremely disturbed" about their
pregnancies rated their children's health as poorer than did the
women who were pregnant later. Author-abstract.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).
LG English (EN).
AB Nuclear energy's share of the world electricity market has been growing over the past 35 years. In 1989, eight generating units entered commercial operation abroad and *three* new units were licensed in the U.S. In early 1990, Mexico became the 26th country to produce electricity from nuclear power. Currently the 426 operating reactors supply one sixth of the world's total electrical capacity. Fourteen countries have now operated nuclear plants for 20 or more years. Since 1980, France has been the leader in the use of nuclear power and currently generates *three* quarters of its electricity from 54 nuclear plants. The U.S. has 112 nuclear plants, the largest number of any country in the world. These plants satisfy almost 20 percent of U.S. electrical energy requirements. Last year *Three* *Mile* *Island,* the would-be icon for everything that is wrong with the nuclear industry was rated as the most efficient nuclear plant in the world. The worldwide trend toward acceptance of nuclear is improving slightly, but many political and societal issues need to be resolved. Whereas recent polls indicate that a majority of the people realize nuclear must be a major contributor to the energy mix of the future, many are reluctant to support the technology until the issue of waste disposal has been resolved. Fears of another Chernobyl, lack of capital, and a new anti-nuclear campaign by Greenpeace will keep the nuclear debate alive in many countries. Additional stumbling blocks in the U.S. include the need to develop a new generation of improved reactor designs which emphasize passive safety features, standardized designs and a stream-lined federal licensing process. Nuclear power is really not dead. Even environmentalists are starting to give it another look. A nuclear renaissance will occur in the U.S. How soon or under what conditions remain to be seen. The next crisis in the

U.S. will not be a shortage of energy, rather a shortage of electricity.(ABSTRACT TRUNCATED AT 250 WORDS). Author-abstract. 42 Refs.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB As a public charge, cancers among the 159,684 residents living within a *10-mile* (16-km) radius of the *Three* *Mile* *Island* nuclear plant were studied relative to releases of radiation during the March 28, 1979, accident as well as to routine plant emissions. The principal cancers considered were leukemia and childhood malignancies. Estimates of the emissions delivered to small geographic study tracts were derived from mathematical dispersion models which accounted for modifying factors such as wind and terrain; the model of accident emissions was validated by readings from off-site dosimeters. Incident cancers among area residents for the period 1975-1985 (n = 5,493) were identified by a review of the records at all local and regional hospitals; preaccident and postaccident trends in cancer rates were examined. For accident emissions, the authors failed to find definite effects of exposure on the cancer types and population subgroups thought to be most susceptible to radiation. No associations were seen for leukemia in adults or for childhood cancers as a group. For leukemia in children, the odds ratio was raised, but cases were few (n = 4), and the estimate was highly variable. Moreover, rates of childhood leukemia in the *Three* *Mile* *Island* area are low compared with national and regional rates. For exposure to routine emissions, the odds ratios were raised for childhood cancers as a whole and for childhood leukemia, but confidence intervals were wide and included 1.0. For leukemia in adults, there was a negative trend. Trends for two types of cancer ran counter to expectation. Non-Hodgkin's lymphoma showed raised risks relative to both accident and routine emissions; lung cancer (adjusted only indirectly for smoking) showed raised risks relative to accident emissions, routine emissions, and background gamma radiation. Overall, the pattern of results does not provide

convincing evidence that radiation releases from the *Three* *Mile*
Island nuclear facility influenced cancer risk during the limited
period of follow-up. Author-abstract.

AB Psychological stress has been shown to affect immune system status
and function, but most studies of this relationship have focused on
acute stress and/or laboratory situations. The present study
compared total numbers of leukocytes and lymphocyte subpopulations
(determined by flow cytometry) and antibody titers to latent and
nonlatent viruses among a group of chronically stressed individuals
living near the damaged *Three* *Mile* *Island* (TMI) nuclear power plant
with those of a demographically comparable control group. Urinary
catecholamine and cortisol levels were also examined. Residents of
the TMI area exhibited greater numbers of neutrophils, which were
positively correlated with epinephrine levels. The TMI group also
exhibited fewer B lymphocytes, T-suppressor/cytotoxic lymphocytes,
and natural killer cells. Antibody titers to herpes simplex were
significantly different across groups as well, whereas titers to
nonlatent rubella virus as well as IgG and IgM levels were
comparable. Author-abstract.

 AB This study examines the stress-related behavioral effects that may be associated with living near an ambient stressor: a toxic-waste landfill. Results are based on a telephone survey of 426 persons living in *three* distance strata from the landfill (within 1 1/2 *miles,* 1 1/2 to 5 *miles,* and 5 to 10 *miles*).* The instrument was adapted from the Hopkins Life Checklist (SCL-90) and from surveys used by researchers studying the effects of the *Three* *Mile* *Island* nuclear accident. No significant differences were found across area or amount of stimuli exposure on the dependent variables of bodily effects, anger-hostility, and demoralization. Scattered effects across age, sex, educational level, and home ownership (v rental) occurred; however, these could not be attributed solely to the landfill. Author-abstract.

JT ARCHIVES OF ENVIRONMENTAL HEALTH.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Studies of Memphis and *Three* *Mile* *Island* have noted a positive
association between actual residential distance and public concern
about exposure to the potential of contamination, whereas none was
found at Love Canal. In this study, concern about environmental
contamination and exposure was examined in relation to both perceived
and actual proximity to a toxic waste disposal site (TWDS). It was
hypothesized that perceived residential proximity would better

predict concern levels that would actual residential distance. The data were abstracted from a New York State, excluding New York City, survey using all respondents (N = 317) from one county known to have a large number of TWDs. Using linear regression, the variance explained in concern scores was 22 times higher with perceived distance than for actual distance. Perceived residential distance was a significant predictor of concern scores, while actual distance was not. However, perceived distance explained less than 5% of the variance in concern scores.  LG English (EN).
 AB On April 28, 1986 heavy radioactive fallout from an unknown source
 was reported from Sweden. Later, it was discovered that two days
 earlier, a nuclear power reactor at Chernobyl, in the Soviet Union,
 had exploded releasing an enormous cloud of effluent containing 40
 million Ci of ¹³¹I, 3 million Ci of ¹³⁷Cs, and 50 million Ci of xenon
 radioisotopes. This far exceeded the 15 Ci of ¹³¹I escape in the
 notorious *Three* *Mile* *Island* accident. Chernobyl reactor IV, of an
 antiquated design, was a graphite-moderated reactor which suffered a
 steam explosion when the operating staff attempted an experiment
 involving preservation of safety functions during a planned shutdown.
 Following the explosion, a fire started in the graphite core which
 required ten days to control. Thirty-one persons died, two in the
 initial explosion and 29 of various combinations of thermal and
 radiation burns, and gamma irradiation. Existing emergency plans
 were invoked involving treatment on the scene and evacuation of
 seriously injured patients to a special hospital in Moscow, as well
 as to nearby Kiev. Later, 135,000 residents of the immediate
 neighborhood were surveyed and evacuated after fallout radiation
 levels began to rise. Fallout patterns around Europe and the
 northern hemisphere were closely tracked. Consequences of the
 accident in human and monetary terms will require years of
 evaluation. Although the United States has no power reactors of the
 Chernobyl type, the country does have a radiation disaster management
 plan, often rehearsed at the state level. As a consequence of
 Chernobyl certain international agreements dealing with radiation
 disaster information and management have been forged.

 Island.

SO J-Human-Stress. 1987 Summer. 13(2). P 75-83.

JT JOURNAL OF HUMAN STRESS.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB The present study was concerned with the relationship between chronic
 stress and sleep disturbance. Previous research has provided
 evidence of chronic stress responding among people living near the
 Three *Mile* *Island* nuclear generating facility. Compared to control
 subjects, the TMI group has exhibited greater symptom reporting,
 poorer performance on behavioral measures of concentration, and
 elevated levels of urinary norepinephrine and epinephrine. Other
 research has suggested a relationship between arousal and insomnia.
 The extent to which stress and sleep disturbances were experienced by
 residents at TMI was examined and compared to levels of stress and
 sleep disturbance among a group of control subjects. The
 relationship between stress and sleep disturbances was also examined.
 Results indicated that TMI area residents exhibited more stress than
 the controls and reported greater disturbance of sleep. Modest
 relationships among stress and sleep measures suggested that the
 symptoms of stress measured in this study were not primary
 determinants of sleep problems. Author-abstract.

SO Am-J-Community-Psychol. 1987 Apr. 15(2). P 167-84.

JT AMERICAN JOURNAL OF COMMUNITY PSYCHOLOGY.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB The investigation directly compared the long-term mental health consequences of two community-wide stressors, the *Three* *Mile* *Island* (TMI) nuclear accident and widespread unemployment due to layoff, in demographically comparable samples of women. Results showed a marked degree of similarity in the stressors' effects: Levels of subclinical symptomatology were elevated to similar degrees in each sample during the year following stressor onset, and symptom levels remained elevated in each sample 2 to 3 1/2 years later. Moreover, variables identified as predictors of enduring psychological distress were virtually identical for the two samples. Additional analyses revealed that the mental health status of unemployed husbands mediated the negative psychological effects of layoff on their wives. Implications of these results for understanding the long-term consequences of exposure to community-wide stress are discussed. Author-abstract.

AB The causes and progress of the accident at Chernobyl are described,
and a comparison between the Chernobyl accident and the 1979 accident
at the *Three* *Mile* *Island* nuclear power station is made. Significant
similarities between Chernobyl and *Three* *Mile* *Island* include
complacency of operators and industry, deliberate negation of safety
systems, and a lack of understanding of their plant on the part of
the operators, which shows the critical importance of the human
element. The Chernobyl accident has implications for nuclear power
in the United States; it will affect the research program of the
Nuclear Regulatory Commission, regulation of Department of Energy
reactors, new reactor designs, and public attitudes.

 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB About 20% of the Swedish land area was considerably contaminated by
 radionuclides released by the *nuclear* *accident* at Chernobyl, Ukraine,
 in April 1986. However, less than 10% of the arable land was
 contaminated. The heavy contamination was closely correlated with
 the amount of rain received during the first days of May 1986.
 Immediate restrictions on grazing limited the early uptake of
 contaminants in animal products. Changes in management of animals,
 especially sheep, goats, and reindeer in the contaminated areas have
 effectively reduced the transfer of radionuclides to human beings.
 One important factor was the possibility of obtaining uncontaminated
 feeds from unaffected parts of the country. The direct costs during
 the first 2 years after the *accident* were approximately +10 million
 for analyses and +90 million for compensation to farmers for
 condemned products (milk, mutton, and reindeer meat) and
 reimbursement for purchase of uncontaminated feeds from other parts
 of the country. Author-abstract.

AB The immediate medical response to the *nuclear* *accident* at the
Chernobyl *nuclear* power station involved containment of the
radioactivity and evacuation of the nearby population. The next step
consisted of assessment of the radiation dose received by
individuals, based on biological dosimetry, and treatment of those
exposed. Medical care involved treatment of skin burns; measures to
support bone marrow failure, gastrointestinal tract injury, and other
organ damage (ie, infection prophylaxis and transfusions) for those
with lower radiation dose exposure; and bone marrow transplantation

for those exposed to a high dose of radiation. At Chernobyl, two victims died immediately and 29 died of radiation or thermal injuries in the next three months. The remaining victims of the *accident* are currently well. A *nuclear* *accident* anywhere is a *nuclear* *accident* everywhere. *Prevention* and cooperation in response to these *accidents* are essential goals. Author-abstract.

LG German (GE).
AB Both determination and significance of radiation exposure limits are dependent on the respective situation. The simplest case is the determination of limits for direct effect of a clearly defined radiation dose upon organism, which occurs at doses above a value of about 25 rem. Determination and significance of a limiting value for the maximum permissible dose for radiation workers are also obvious; it indicates the calculated increase of risk and its value (5 rem/a) refers to the "tolerated risk" in other professions. An essentially different situation occurs if the radiation doses in question are far below 5 rem/a, as it is the case in consequence of the Chernobyl *nuclear* *accident.* In this case there is no opportunity of determining a relation between radiation dose and its effect in a scientific and objective way: the relation is postulated by extrapolation of the calculated values. There are two possible solutions: either determination of the limit as a certain fraction of the limiting value for professional exposure (as it has been practiced in France and Switzerland), or consideration of the ICRP

recommendation to keep the limits "as low as reasonably achievable" with regard to social, economical and psychological factors. Austria has chosen this solution. Public information about origin and meaning of these limiting values is a necessary condition to avoid that a value above the limits is considered necessarily harmful.

AB The principles of radiation protection for the population in Austria as applied in context with the catastrophic releases of radioactivity from the Chernobyl *nuclear* power reactor are presented. The main results of the first air filter analyses, which allowed an identification of the problem are discussed. The following measurements show, that after radioactive decay of Iodine-131, the main route for intake of Cesium-137 will be ingestion with the foodstuffs over a longer period. Dose estimations give 80 to 100 mrem/year (0.8 to 1.0 mSv/a) effective committed dose equivalent caused by the *nuclear* *accident.* Author-abstract.

AB The medical care given to a victim of a radiation *accident* is one aspect of a larger emergency response that involves the establishment of control of the radiation source, *prevention* of secondary contamination of all persons having contact with the injured, organization of a general evacuation, and panic control. We have discussed the basic knowledge required to render medical care within the first few hours and days following an industrial *nuclear* incident. The fact that we have such knowledge should not be taken as an argument for the survivability of populations whose countries contemplate *nuclear* wars. At Chernobyl, radiation acutely injured about 300 persons and killed at least 31. And yet the enterprise needed to deal with the injured, the dying, and the evacuation of thousands taxed the medical resources of a superpower. Clearly, even the limited medical response available to physicians treating radiation victims rests on an infrastructure of facilities, equipment, drugs, transportation, communication, and organization that would surely be destroyed or severely incapacitated in a *nuclear* exchange. JT CANADIAN JOURNAL OF ANAESTHESIA.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB The occurrence of serious accidents in complex industrial systems such as at *Three* *Mile* *Island* and Bhopal has prompted development of new models of causation and investigation of disasters. These analytical models have potential relevance in anaesthesia. We therefore applied one of the previously described systems to the investigation of an anaesthetic accident. The model chosen describes two kinds of failures, both of which must be sought. The first group, active failures, consists of mistakes made by practitioners in the provision of care. The second group, latent failures, represents flaws in the administrative and productive system. The model emphasizes the search for latent failures and shows that *prevention* of active failures alone is insufficient to avoid further accidents if latent failures persist unchanged. These key features and the utility of this model are illustrated by application to a case of aspiration of gastric contents. While four active failures were recognized, an equal number of latent failures also became apparent. The identification of both types of failures permitted the formulation of recommendations to avoid further occurrences. Thus this model of accident causation can provide a useful mechanism to investigate and possibly prevent anaesthetic accidents.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB The causes and progress of the accident at Chernobyl are described, and a comparison between the Chernobyl accident and the 1979 accident at the *Three* *Mile* *Island* nuclear power station is made. Significant similarities between Chernobyl and *Three* *Mile* *Island* include complacency of operators and industry, deliberate negation of safety systems, and a lack of understanding of their plant on the part of the operators, which shows the critical importance of the human element. The Chernobyl accident has implications for nuclear power in the United States; it will affect the research program of the Nuclear Regulatory Commission, regulation of Department of Energy reactors, new reactor designs, and public attitudes.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Tested in a field experiment (N = 647) the hypothesis that perceptions of personal susceptibility are important in decisions to test one's home for radioactive radon gas. Experimental group subjects received a personal telephone call to tell them they lived in a high-risk area and a personal letter to reinforce the telephone message. After the intervention, experimental subjects were significantly more likely than minimal-treatment subjects to acknowledge the possibility of high radon levels in their homes.

Perceptions of susceptibility and illness severity were significantly correlated with orders of radon test kits and with testing intentions. Nevertheless, there were no differences between groups in test orders or intentions. Results are discussed in terms of the difficulty of getting people to acknowledge susceptibility and the factors other than risk perceptions that influence self-protective behavior. Author-abstract.

AB In-depth interviews with seven atomic veterans and their families indicated powerful psychological effects on all family members from exposure to low-level ionizing *radiation.* Four themes emerged: the invalidation of their experiences by government and other authority figures; family concerns about genetic effects on future generations; family members' desire to protect each other from fears of physical consequences; and desire to leave a record of their experiences to help prevent future suffering. AB Phenomenology and time course of psychic disorders in persons exposed
to life-threatening emergency situations provoked by the Chernobyl
accident have been analyzed. Three states could be identified
according to differences in their psychogenic impact: acute, delayed
and long-term. Psychic dysadaptation and disorders might be
presented as results of a single process beginning with acute anxiety
responses followed by asthenic disorders which backed the relatively
steady neurotic and psychopathic states. Author-abstract.

AB Invisible environmental contaminants are those contaminants that
possess environmental and/or medical invisibility. Recent studies
indicate: (1) that these contaminants can and do have traumatic
psychological effects on those individuals who have been exposed to
them and (2) that there is a remarkable uniformity to these traumatic
affects as they have been found in the various invisible exposures

that have been studied to date. The common denominators in all of these situations is the invisibility of the involved contaminants. The adverse psychological effects of the invisible contaminants are as follows: (1) experienced uncertainty, (2) adaptational dilemmas, (3) hypervigilance, (4) nonempirical belief systems about the exposure, and (5) traumatic neuroses. This paper will: (1) review the data that documents the occurrence of psychological effects of the invisible environmental contaminants, (2) present an adaptational model that explains the manner in which these psychological trauma develop, and (3) examine the clinical and public policy implications of these findings. PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Currently available treatments for *radiation-induced* nausea and vomiting either are ineffective or reduce performance. The new antiemetic and gastrokinetic agent zacopride was tested in rhesus monkeys to assess its behavioral toxicity and its ability to inhibit *radiation-induced* emesis. Zacopride (intragastric, 0.3 mg/kg) or a placebo was given blindly and randomly in the basal state and 15 min before a whole-body 800 cGy 60Co *gamma-radiation* dose (except for the legs which were partially protected to permit survival of some bone marrow). We determined (1) gastric emptying rates; (2) the presence and frequency of retching and vomiting; and (3) the effect of zacopride on the performance of a visual discrimination task in nonirradiated subjects. No vomiting, retching, or decreased performance was observed after either placebo or zacopride in the control state. Following irradiation plus placebo, 70 emeses were observed in 5 of 6 monkeys, and 353 retches were observed in all 6 monkeys. In contrast, only 1 emesis was observed in 1 of 6 monkeys.

and 173 retches were seen in 4 of 6 monkeys after irradiation plus zacopride (P less than 0.01). Zacopride also significantly inhibited *radiation-induced* suppression of gastric emptying. When given after the first vomiting episode in a separate group of irradiated monkeys, zacopride completely prevented any subsequent vomiting. The present results demonstrate that intragastric administration of zacopride significantly inhibited *radiation-induced* retching, vomiting, and suppression of gastric emptying in rhesus monkeys and did not cause detectable behavioral side effects when given to nonradiated monkeys. This observation has important implications in the treatment of *radiation* sickness. Author-abstract.

AB Three hundred fifty-seven college students were surveyed to assess later adolescents' awareness of the status of nuclear arms development and possible effects of a nuclear war on people and the environment. Chi-square analyses were performed to determine whether the frequency of correct responses differed with regard to participants' sex, political orientation, and position toward the United States' possession of nuclear weapons. Results suggest that later adolescents are extremely uninformed regarding the current status of nuclear issues and the consequences of a nuclear war.

These data, coupled with findings from previous studies reporting children's and adolescents' concerns and fears about nuclear war, indicate that there is a strong need to educate young people concerning nuclear issues. Author-abstract.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB In December 1973 a technician was accidentally irradiated when attempting to bring under control a sealed 60Co source (110 TBq) which had been lodged in the head of a medical irradiation unit during a replacement operation. In the early period after the accident, severe skin changes on the left hand, epilation in a small area of the left temporal region and minor deviations in peripheral blood developed. In the following years, repeated surgery due to secondary skin defects of the left hand resulted in the loss of the fingers 2-5. Since 1975, changes in the lens of the left eye began to appear leading gradually to the deterioration of visual acuity. Later, opacities of the lens of the right eye were found. The patient's psychological and emotional attitude about the accident changed in the course of time. The factors influencing the psychic

state of the patient are identified. Author-abstract.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB We have tried to estimate the toxic potential of *waste* from *nuclear* power plants and from power plants burning fossil fuels. The potential risks have been expressed as 'risk potentials' or 'person equivalents.' These are purely theoretical units and represent only an attempt to quantify the potential impact of different sources and substances on human health. Existing concentration limits for effects on human health are used. The philosophy behind establishing limits for several carcinogenic chemicals is based on a linear dose-effect curve. That is, no lower concentration of no effect exists and one has to accept a certain small risk by accepting the concentration limit. This is in line with the establishment of limits for radiation. *Waste* products from coal combustion have the highest potential risk among the fossil fuel alternatives. The highest risk is caused by metals, and the fly ash represents the effluent stream giving the largest contribution to the potential

risk. The *waste* from *nuclear* power production has a lower potential risk than coal if today's limit values re used. If one adjusts the limits for radiation dose and the concentration limit values so that a similar risk is accepted by the limits, *nuclear* *waste* seems to have a much higher potential risk than *waste* from fossil fuel. The possibility that such risk estimates may be used as arguments for safe storage of the different types of *waste* is discussed. In order to obtain the actual risk from the potential risk, the dispersion of the *waste* in the environment and its uptake and effects in man have to be taken into account. Author-abstract.

AB This study investigates the potential impacts of the proposed *nuclear*
 waste repository at Yucca Mountain, Nevada, upon tourism, retirement
 and job-related migration, and business development in Las Vegas and
 the state. Adverse impacts may be expected to result from
 perceptions of risk, stigmatization, and socially amplified reactions
 to "unfortunate events" associated with the repository (major and
 minor accidents, discoveries of radiation releases, evidence of
 mismanagement, attempts to sabotage or disrupt the facility, etc.).
 The conceptual underpinnings of risk perception, stigmatization, and
 social amplification are discussed and empirical data are presented
 to demonstrate how *nuclear* images associated with Las Vegas and the
 State of Nevada might trigger adverse economic effects. The
 possibility that intense negative imagery associated with the
 repository may cause significant harm to Nevada's economy can no
 longer be ignored by serious attempts to assess the risks and impacts
 of this unique facility. The behavioral processes described here
 appear relevant as well to the social impact assessment of any
 proposed facility that produces, uses, transports, or disposes of
 hazardous materials. Author-abstract.

 LG English (EN).
 AB Various situations are described in which societal action may be
 interpreted as a dollar value placed on averting a human fatality,
 and numerical values are derived in each case. Situations included
 are a variety of medical screening and medical care programs and of
 automobile and highway safety measures, food for overseas relief, air
 pollution control, fire prevention, industrial safety, and several
 radiation-related activities including standards for radium in
 drinking water, radwaste systems in *nuclear* plants, and defense and
 civilian high-level *waste* management. Values varying from a few
 thousand dollars to hundreds of millions of dollars per fatality
 averted are obtained. An attempt to derive data of this type from

polling is described. The problem of discounting when money is spent now to save lives far in the future (as with *nuclear* *waste*) is discussed. It is concluded that nearly all of the vast variation in the results is unjustified and represents a need for educating the public, especially in the area of radiation protection.

TI The *nuclear* power industry in the United States: status and projections.
SO Semin-Nucl-Med. 1988 Jan. 18(1). P 25-35.
JT SEMINARS IN *NUCLEAR* MEDICINE.
PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).
LG English (EN).
AB One sixth of the electricity in the United States is now being generated in *nuclear* power plants, a remarkable achievement for a technology whose basic *nuclear* reaction was not even known 50 years ago. On the other hand, many of the nation's electric utilities are experiencing great difficulties completing the construction of their *nuclear* plants; 41 partially constructed plants have been abandoned. Those abandoned plants plus about 110 in operation and 15 still to be completed comprise the first generation of *nuclear* power plants in the United States. When, and even if, there will be a second generation is much in doubt. Data are presented to show that the absence of a second generation of *nuclear* plants will place large demands on the fossil fuels, with attendant high energy prices and high environmental costs the expected outcome. It appears that the future will bring large economic forces to start new orders for *nuclear* plants. On the other hand, the opposing institutional forces appear equally strong. Among the problems creating these institutional forces are the difficulty the United States is having in finding a politically acceptable approach to *nuclear* *waste* disposal and the vulnerability of power plant builders and operators to litigation and high financial risk. At present, the issue of a second generation of *nuclear* plants is stalemated. Author-abstract. 17 Refs.

TI A review of the high-level *nuclear* *waste* repository siting analysis.
SO Risk-Anal. 1987 Jun. 7(2). P 219-23.
JT RISK ANALYSIS.
PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB We critique two 1986 Department of Energy reports concerning the selection of sites for characterization as the nation's first high-level *nuclear* *waste* repository. We find that the multiattribute utility analysis of the five nominated sites was well done, although we express concern about the assessed probabilities, question the construction of two important attribute scales, and disagree with some of the value tradeoffs that were used. In contrast, we find the logic of the recommendations report to be weak and unconvincing.

TI An analysis of the portfolio of sites to characterize for selecting a *nuclear* repository.

SO Risk-Anal. 1987 Jun. 7(2). P 195-218.

JT RISK ANALYSIS.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB The U.S. Department of Energy has selected three sites, from five nominated, to characterize for a *nuclear* repository to permanently dispose of *nuclear* *waste.* This decision was made without the benefit of an analysis of this "portfolio" problem. This paper analyzes different portfolios of three sites for simultaneous characterization and strategies for sequential characterization. Characterization of each site, which involves significant subsurface excavation, is now estimated to cost \$1 billion. Mainly because of the high characterization costs, sequential characterization strategies are identified which are the equivalent of \$1.7-2.0 billion less expensive than the selected DOE simultaneous characterization of the three sites. If three sites are simultaneously characterized, one portfolio is estimated to be the equivalent of \$100-400 million better than the selected DOE portfolio. Because of these potential savings and several other complicating factors that may influence the relative desirability of characterization strategies, a thorough analysis of characterization strategies that addresses the likelihood of finding disqualifying conditions during site characterization, uncertainties, and dependencies in forecast site repository costs,

preclosure and postclosure health and safety impacts, potential delays of both sequential and simultaneous characterization strategies, and the environmental, socioeconomic, and health and safety impacts of characterization activities is recommended.

AB Immunizations have been among the most successful of preventive
interventions. However, concern exists in the United States that
recent epidemics of vaccine-preventable diseases and low rates of
childhood immunizations may signal the existence of major underlying
problems in immunization policy. Additionally, the effectiveness of
national, state, and local public health programs in administering
these and other preventive services to children has been called into
question. This article examines the current state of childhood
immunizations in this country and offers a broad range of suggestions
for policy modification. Author-abstract.

 AB The clinical activities of the Baffin Consultation Service of the Clarke Institute of Psychiatry were examined. Demographic and clinical data are described based on clinical interviews and questionnaire items from 581 initial psychiatric referrals. More women than men were referred to the service; the mean age of the patients seen was 27.3 +/- 13.4 years. The majority of referred patients were single and unemployed. The most common reasons for referral were depression, suicidal ideation, suicide attempts and family problems. The major diagnoses made were adjustment reactions and depressive disorders. Treatment was largely carried out in an

outpatient setting through local health care professionals. The implications of these findings for this population and the development of community-based intervention programs are discussed. Author-abstract.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB The West Virginia School of Osteopathic Medicine (WVSOM) educated and
retained more primary care physicians for practice in rural
Appalachia than did any other U.S. medical school from 1978 through
1990. This article describes the most important methods used at
WVSOM to place physicians in rural areas: (1) The school has a
focused, achievable mission (to provide primary care physicians who
are trained to meet the medical needs of rural Appalachia and to
improve the health care of the rural Appalachian population) that is
agreed upon by the administration, faculty, and students; (2) it
participates in a multistate educational exchange program with a
similar mission; (3) it emphasizes personalized and interactive
recruiting, admission, and placement processes aimed to attract
nontraditional, rural students; (4) it provides early and long-term
clinical training in rural sites (both hospitals and physicians'
offices); (5) it is dedicated primarily to the education of medical
students rather than to research or other goals; and (6) it is a
freestanding school in a rural environment. The authors state that
although WVSOM is unusual in some respects, at least some of its
methods may be useful to other medical schools as they seek to
produce more primary care physicians for rural and other *underserved*
areas. Author-abstract.

 AB It is recognized that health care in rural communities could be improved significantly with the assistance of telehealth, the term by which the combined application of computer and telecommunications technologies to health care has come to be known. Yet in spite of its obvious potential, the telehealth literature has shown a surprising lack of growth. This paper reports an analysis which revealed that, between 1975 and 1990, few telehealth articles were catalogued by the National Library of Medicine, and suggests why this might have been the case. Following a brief discussion of the origins of telehealth, terminology, and the rural health care crisis, this overview examines the status of telehealth in terms of its main applications: telemedicine and tele-education. An analysis of the pattern of publications between 1975 and 1990 is then used to suggest why telehealth has not fulfilled its potential. Corrective measures are proposed and the paper concludes with a summary of recent telehealth initiatives. Author-abstract.

10.5 million inhabitants of the rural *underserved* areas, with federal
government resources in 18 states. This study compares the structure
and functioning of the IMSS-Solidaridad Program with Local Health
Systems, as they have been proposed by the Panamerican Health
Organization for country members and by the Ministry of Health of
Mexico, particularly in relation to the decision-making process at
local level. Some assets and limitations of the IMSS-Solidaridad
Program are analyzed and, finally, concrete procedures to improve
coordination between the IMSS-Solidaridad Program and other health
services for similar populations (populations without social security
protection) in Mexico are suggested, with the purpose of using
resources more adequately and succeed in the national goal to achieve
equity in health. Author-abstract.

AB AIDS is inexorably involving all parts of the country and all strata

of society, with 10% of the urban and 3% of the rural population infected with HIV. It is increasingly a disease of women and children. The major cofactors for transmission are also sexually transmitted. For most developing countries, in spite of all education efforts, the "silent epidemic" of AIDS continues. AIDS is known but not understood; counselling modifies behavior in only 10-20% of at-risk persons. Under optimal conditions, HIV discordant females have seroconversion rates of 4.7% per year and pregnancy rates of 10.4% per year. The recent political unrest in Zaire and Haiti will further enhance the spread of AIDS in these countries. Despite these difficult periods, the work can and must continue. After all, during our 10th year of collaboration with a Haitian private research group, the Haitian government and Cornell University, Haiti has known seven different political rulers. Finally, I want to make a pledge on behalf of the millions of people who face a certain death from HIV infection and AIDS and who will never make the front page of any newspaper. For these people, you can make a difference. You must give us the tools to carry on this fight. The clinical trials must be done where they are most needed: the developing countries. Vaccines represent the only viable alternative despite the recognized obstacles of viral heterogeneity, immunogenicity, and delivery. Author-abstract.

 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB In the 1970s, Japan's physician manpower policy was to increase the number of medical students and medical schools to ease the difficulties caused by shortage of doctors and their maldistribution. 34 medical schools were established during this time, which eventually doubled the number of newly certificated physicians from about 4000 to about 8000 per year by the mid 1980s. To examine the success of this policy, we analysed the numbers of physicians in relation to the population in all municipal bodies (n = 3268) in Japan. Between 1980 and 1990, the number of practising physicians increased by about 37%, and the ratio of physicians per 100,000 population increased from 127 to 165 throughout the country. However, analyses by the Lorenz curve and the Gini coefficient indicated that the inequality in physician distribution did not improve. While municipal bodies with a population over 30,000 gained

proportionally more physicians, most communities with fewer than 10,000 residents showed little gain. Our findings have important implications for policy changes now being considered by the government to plan the future supply of physician manpower in Japan. A policy that will alleviate physician maldistribution also needs to be devised. Author-abstract.

AB Although the United States spends more on health care than any country in the world, access to that care is becoming increasingly difficult. The National Cancer Institute and other federal agencies are sponsoring innovative research for delivering effective medical services, particularly to *underserved* populations. Models of successful collaboration between private and public sectors concerned

with health care can be adapted and implemented at the national, state, and local levels. However, other measures are needed to ensure access to adequate health care for all Americans. Minimal but effective regulations are needed to ensure quality control, reduce duplication of services, and minimize cost increases. Public and private sectors also need to consider ways to extend adequate health insurance coverage to all Americans and to provide compensation for preventive services. Author-abstract.

AB We describe how the federal government, the City of Chicago, and the State of Illinois worked together to increase the availability and accessibility of health care services on Chicago's *underserved* west side by reopening a bankrupt, federally-funded community health center. The federal government made the building available to the City which then contracted with a state university medical center to be the provider of services. This partnering has allowed the Chicago Department of Health to offer services in a previously *underserved* area. The University has gained an opportunity for community-based primary care teaching, as well as community relations. Patients have increased access to a wide variety of specialty and inpatient care. If public health providers are to be successful in this financial climate, they must look to new partners and new ways of delivering services to increase availability of services at a time when they are greatly needed. AB The authors review curricular characteristics of combined baccalaureate-M.D. programs at 28 U.S. medical schools from 1961, when the first programs started, until 1991-92. Initially, in the 1960s, these programs were created (1) to offer talented high school graduates an accelerated track leading to the baccalaureate and M.D. degrees, (2) to reduce educational expenses, (3) to improve education in the humanities, and (4) to attract outstanding students into careers in medicine. In the 1970s these objectives were modified to address national health care needs, particularly the need to graduate more physicians more quickly, especially primary care physicians for *underserved* areas. In the 1980s the objectives were broadened to achieve more diverse goals, including emphases on the humanities, community medicine, and biotechnology, in addition to the continued stress on the education of primary care physicians.

 SO Soc-Sci-Med. 1992 Oct. 35(8). P 1015-25.
 JT SOCIAL SCIENCE AND MEDICINE.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB Sale of modern medicines by untrained peddlers, general merchants,
 and other drug sellers is common throughout the developing world.
 Drug sellers operating in the 'informal sector' are often the first
 source of health care outside the home. Reasons given by patients
 for using private drug sellers include expediency, convenience,
 efficacy of the medicines, dependability of supply, and reasonable
 cost. At the same time, self-medication through private drug sellers
 can be ineffective, wasteful, and at times distinctly harmful.
 Regulatory approaches to controlling drug selling in the informal
 sector, widely endorsed on paper through national drug control
 legislation, require a cadre of professional regulatory staff and
 enforcement mechanisms which are too often beyond the current
 economic and political reach of countries. In Nepal, where rugged
 terrain has limited infrastructure development, the doctor to
 population ratio is 1:23,000, utilization of government health
 services averages only 0.2 visits per person per year. Retail drug
 outlets outnumber health posts and health centers by a ratio of 4:1
 and private drug sellers often offer the only access to modern
 medicine for much of the population. Community surveys have found
 that drug retailers are very often the first and only source of
 health care outside the home. Given the importance of retail drug
 outlets and the lack of trained pharmacists, the Department of Drug
 Administration in 1981 established a 45-hr course for drug retailers
 which emphasized practical training as well as formal teaching on
 pharmacology, ethics, storage of drugs, and legal issues. By the end
 of 1989, 4096 drug retailers had graduated from the course. Still
 run by the Ministry of Health Department of Drug Administration, the
 course has proven to be administratively feasible and has been quite

popular with drug retailers. Initial reservations expressed by doctors and some pharmacists were soon overcome, and the course is now well accepted by professional groups. Because the course is offered in different locations, geographic coverage has also been very good despite Nepal's logistic constraints. The operating cost of the course averages about U.S. \$18 per trainee. Informal evaluations have resulted in plans for refresher training more narrowly focused on safe dispensing and appropriate referral for a limited number of important public health problems. Since 50-90% of pharmaceutical expenditures typically pass through the informal private sector in developing countries, it is suggested that other countries consider focused drug retailer training as a response to the problems of manpower shortages and drug dispensing by unqualified staff. Author-abstract.

 AB Minnesota's health care reform plan (by any name) is a
 cost-containment bill with provisions to provide health insurance for
 some uninsured people, to examine quality of care, to increase
 support for rural provider education and migration to rural practice,
 and to develop state and regional health planning procedures. It is
 an ambitious bill with very tight time frames, vague language, and
 heavy reliance on regional commissions and volunteer groups that are
 just now being established. Will it have an impact on rural health
 care? Undoubtedly, it will. But somewhere between what the bill
 says and the desired outcome is a void that physicians can help fill
 with constructive work and criticism. If physicians do not take the
 lead, someone else will fill that void--nonphysician providers,
 legislators, bureaucrats, or consumers. Or the structure could
 implode, taking all of us with it. Author-abstract.

 AB A collaboration established in 1974 between the Pennsylvania State Office of Mental Health and Western Psychiatric Institute and Clinic of the University of Pittsburgh Medical Center provides a comprehensive program of continuing mental health education, skills development, and program consultation to state hospitals and publicly

funded community programs in rural and semirural western Pennsylvania. The authors describe the development of the program and discuss its current organization and activities. In 1990-91 a total of 60 faculty and 150 staff members from the institute contributed more than 1,200 hours of direct programming. The collaboration's activities have broadened in both hospital and community sectors and currently involve all of the university's health and medical care schools. Author-abstract.

AB OBJECTIVE--To examine the hypothesis that medical schools vary
systematically and predictably in the proportion of their graduates
who enter rural practice. DESIGN--The December 1991 version of the
American Medical Association Physician Masterfile was used to examine
the rural and urban practice locations of physicians who graduated
from American medical schools between 1976 and 1985. Selected
characteristics of the medical schools--including location,
ownership, and funding--were linked to the Physician Masterfile.
MAIN OUTCOME MEASURES--The percentage of the graduates from each

medical school who were practicing in rural areas in December 1991, disaggregated by physician specialty. RESULTS--Of the practicing graduates from our study, 12.6% were located in rural counties; family physicians were much more likely than members of other specialties to select rural practice, particularly in the smallest and most isolated rural counties. Women were much less likely than men to enter rural practice. Medical schools varied greatly in the percentage of their graduates who entered rural practice, ranging from 41.2% to 2.3% of the graduating classes studied. Twelve medical schools accounted for over one quarter of the physicians entering rural practice in this time period. Four variables were strongly associated with a tendency to produce rural graduates: location in a rural state, public ownership, production of family physicians, and smaller amounts of funding from the National Institutes of Health. DISCUSSION--The organization, location, and mission of medical schools is closely related to the propensity of their graduates to select rural practice. Increasing policy coordination among medical schools and state and federal governmental entities would most effectively address residual problems of rural physician shortages. Author-abstract.

AB OBJECTIVE--To contrast the retention of physicians serving National Health Service Corps (NHSC) Scholarship Program obligations in rural settings to that of non-NHSC physicians working in the same or similar practices, and to identify promising retention-enhancing strategies. DESIGN--Cohort study. PARTICIPANTS--Four hundred twelve primary care physicians initially identified during an earlier study as working in a national stratified random sample of 178 externally subsidized rural clinics in 1981. Thirty-six percent were serving obligations to the NHSC, nearly all through the NHSC's Scholarship Program. The NHSC and non-NHSC inception cohorts (those first coming to their 1981 "index" practices from May 1979 through December 1981) were created from within the entire group for use in most analyses. INTERVENTION--In 1990, physicians were resurveyed to learn of their backgrounds, experiences in their index practices, and their subsequent career moves. RESULTS--By 1984 and in each year thereafter, fewer NHSC than non-NHSC physicians of the entire respondent cohort remained (1) in their index practices, (2) in their index communities, and (3) in practice in any rural county (P less than .001). In the inception cohort, fewer NHSC than non-NHSC physicians were retained within all three settings by the third year after their initial dates of employment (P less than or equal to .01). After 8 years of employment, group retention rates for NHSC and non-NHSC inception cohort physicians were 12% vs 39% in the index practice and 29% vs 52% in nonmetropolitan practice. Physicians in both NHSC and non-NHSC groups who left their index practices generally left rural practice altogether. CONCLUSIONS--When compared to non-NHSC physicians working in comparable rural settings, the retention of rural NHSC physicians is seen to be poor and only partially explained by fixed physician, practice, or community variables. Long-term retention of NHSC providers is now receiving much needed attention at the federal level. Author-abstract.

 JT JOURNAL OF THE AMERICAN BOARD OF FAMILY PRACTICE.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB BACKGROUND: Decreased numbers of obstetric providers during the last
 decade have limited access to obstetrics care, especially for some
 groups of women. Increasing or stabilizing the number of providers
 could increase access. METHODS: A questionnaire was mailed in 1989
 to 1965 Washington State family physicians and obstetricians to
 determine their attitudes toward the practice of obstetrics.
 Sixty-six percent of physicians responded to the survey. RESULTS: Of
 those who had quit obstetrics in the previous 3 years, 42 percent of
 responding family physicians and 19 percent of responding
 obstetricians would consider resuming. Those family physicians
 willing to consider resuming their obstetric practices were more
 likely to have been in practice fewer years, employed by a health
 maintenance organization (HMO), or located in a rural area. A
 majority of all respondents cited excessive malpractice premiums and
 fear of malpractice suit as reasons for stopping obstetric practice.
 Family physicians willing to consider resuming obstetrics were more
 concerned about the overall number of obstetric providers in their
 area. Rural family physicians willing to consider resuming
 obstetrics listed poor backup or shared call more often as a reason
 they had quit. CONCLUSIONS: Attention targeted to the concerns of
 family physicians who have been in practice for a short time, who
 work for HMOs, or who are in rural practice might help induce some
 physicians to resume obstetrics. Author-abstract.

TI Psychiatric admissions and social deprivation: is the Jarman
underprivileged area score relevant?
SO J-Epidemiol-Community-Health. 1992 Jun. 46(3). P 245-7.
JT JOURNAL OF EPIDEMIOLOGY AND COMMUNITY HEALTH.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB STUDY OBJECTIVE--The aim was to assess the relationship between
social deprivation, as measured by the Jarman under-privileged area
score (UPA score), and psychiatric admission rates and length of stay
within an inner London borough. DESIGN--The study was a
retrospective survey of psychiatric admission rates for electoral
wards in the London borough of Islington in relation to Jarman UPA
scores and subscores. SETTING--Islington Health Authority
psychiatric admission wards at the Whittington and Friern Hospitals.
PATIENTS--All admissions during the year of 1985 were studied (n =
778). MAIN RESULTS--No correlation was found between the total
Jarman UPA score and either admission rates or length of stay. There
was, however, a correlation between the Jarman UPA subscore for
ethnic minorities and admission rates ($r = 0.409$, p less than 0.05),
and between the Jarman UPA subscore for lone parents and length of
stay ($r = 0.390$, p less than 0.05). CONCLUSIONS--The Jarman UPA
score at electoral ward level is not related to psychiatric
morbidity, and should not therefore be used for planning local
service provision. Author-abstract.

AB The frequently quoted ratio of 1:10,000 psychiatrists to population originated in Canada in 1962 and was later adopted as the minimum by the American Psychiatric Association. Since then both Canada and the United States have found this ratio to be inadequate. Canada has since advocated an optimal target ratio of 1:6,500, but recommended a more attainable pragmatic ratio of 1:8,000 for the foreseeable future. The Royal Australian and New Zealand College of Psychiatrists' recently recommended range of 1:7,500 to 1:10,000 is applauded. Reasons are given why a reasonable upper limit to the ratio of psychiatrists to population is desirable. Author-abstract. 18 Refs.

AB The main objective of this study was to describe the psychiatric disorders seen in patients presenting for treatment in rural New South Wales. The patients were seen primarily in the community, in both public and private practice, but also in the local base hospital and prison. Seven hundred and seven patients were consecutively

examined during the study period. The results of this study were compared with a previous Australia-wide study to identify specific disorders that were more prevalent in rural areas. Alcohol abuse and dependence stood out as being much more prevalent. Life problems such as domestic violence, sexual assault, and incest occurred commonly in women referred for psychiatric assessment. More than ten percent of the study patients were children aged under 17, who had similar prevalence rates of the various psychiatric disorders to a national comparison. It is concluded that alcohol abuse is very common in rural New South Wales, particularly in men, although there are also high rates in women, and this is probably related, in part at least, to the high rates of domestic violence, sexual assault and incest. It appears probable that there is a cycle of alcohol abuse in men leading to domestic violence and sexual abuse in women and children. This may contribute to the latter becoming anxious and depressed. The rates of the major functional psychiatric disorders were similar to those seen nationally. There is a great need for the maldistribution of psychiatrists between metropolitan and rural areas to be addressed. Author-abstract.

AB This is a description of the psychiatric services at present provided to the Far West Region of New South Wales. On account of the isolation of the region, and noting that the area probably has a higher than normal rate of psychiatric and psycho-social morbidity, there are special problems involved in the provision of comprehensive treatment services. I am the only resident psychiatrist within the region, and work as both a Visiting Medical Officer to the Broken Hill Base Hospital, to Wilcannia Hospital, and to the Prison Medical Service, as well as half time in private practice. The Mental Health Services to the area are at present being considerably expanded, and in this paper their structure and function will be described, and the special problems of providing a comprehensive service to an isolated area of the bush will be discussed. The inequity of service allocation to the region will be highlighted. It is noted that the region's total share of the financial mental health cake has dropped by about 40% in the last ten years as a result of the setting up of local community services and dramatically reduced in-patient hospitalisation costs in Sydney and Adelaide. Author-abstract.

AB The episodes of morbidity over a 6 month period were recorded at 179 households comprising 1715 people living in the district of Bandiagara (Mali). This population was subdivided into groups according to their distances from the nearest district health centre and educational services, their scholarization, socio-economic and hygiene levels. The subjects interviewed were asked to report illnesses using their vernacular names, the type of therapy selected,

the decision process, the time-lapse between onset and remedial action, the treatment undergone and its effect. Subsequent analysis of the data recorded indicates that the frequency of morbidity episodes is inversely proportionate to the household's level of hygiene. It also appears that factors such as the household's hygienic, socio-economic and educational levels along with the type of illness and its duration, are more decisive when resorting (or not resorting) to treatment than is the proximity factor. This seems particularly true in the case of traditional medicine, chosen even where cosmopolitan resources are available and by people with a relatively high socio-economic, hygienic and educational level. In the specific situation under study this paper indicates those areas for further study with a view to improving public health education. Author-abstract.

JT WEST VIRGINIA MEDICAL JOURNAL.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB West Virginia family physicians feel that they are able to assess the
health care needs of their communities. There is a need for more
physicians in all of the major specialties in West Virginia, but the
largest numbers of physicians are needed in family practice and
obstetrics. More registered nurses and licensed practical nurses are
needed than any other health care professionals. Twenty-five percent
of the respondents are actively recruiting associates, and 48 percent
have seriously considered leaving, or are leaving West Virginia. The
most commonly cited reasons for leaving are inadequate reimbursement,
the state's economy, SB-576, lack of tort reform, and state
government in general. The greatest advantage given to practicing in

the state are its people, the quality of life, and home and family. In addition, the greatest problems are reimbursement, state government, the malpractice climate and the state economy. The survey shows that state government needs to show a good faith effort to enact tort reform to improve relations with physicians. The threat of losing more physicians is real and must be addressed. Improving the climate for the practice of medicine is a viable solution to West Virginia's manpower problems. There is also a need to continue all present health care professional training programs. More emphasis should be placed on recruitment and retention of nursing students. There is expressed support for nurse midwives, nurse practitioners, and physicians' assistants all working under the supervision of physicians. The finding that home and family are frequently listed as advantages to practicing here indicates recruitment and nurturing of students from *underserved* areas should be increased.(ABSTRACT TRUNCATED AT 250 WORDS). Author-abstract.

AB This article reports findings from a national random sample of nurse practitioners (NPs) who were actively practicing in adult primary care settings during 1986. An analysis of their demographic and practice characteristics revealed a statistically significant association between certain characteristics and the NPs' prescribing status. Nurse practitioners with prescriptive authority had more years of experience and were more likely to practice in rural or suburban areas and work in nongroup settings than NPs without prescriptive authority. These findings suggest that giving NPs' prescriptive authority may be an enabling factor that supports NP practice in *medically* *underserved* locations. Author-abstract.

AB Studies of doctor location have, for the most part, focused on geographic variations in access to care, rather than the continuity of care provided at different locations. This paper examines regional and city size variations in turnover rates in general practice and shows that they are highest in the southern and most

rural regions of New Zealand. However, an unexpected finding was that no significant differences occurred by doctor origin. While more foreign than New Zealand medical graduates have located in rural New Zealand, similar turnover rates between the two groups indicates that their presence has not resulted in any improvement in the continuity of care provided. Author-abstract.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Although numerous estimates of the prevalence of seizure disorders in
populations in the less developed world have now been published,
these estimates are difficult to interpret due to lack of
comparability of study methods and criteria for case definition. The
results reported in this paper are from a large, collaborative study
of disabilities in 2- to 9-year-old children in which standard
research procedures and case definitions were used in three diverse
populations (located in Bangladesh, Jamaica and Pakistan). A
two-phase study design (screening followed by professional
evaluations) was used in this study allowing for the professional
evaluation to serve as the criterion in the estimation of prevalence,
even for rare disorders. As a result, the prevalence estimates
reported here have a high degree of comparability across populations
and exhibit unusually strong validity for population surveys.
Febrile seizures were the most common type of seizure history in all

three populations, with point estimates of lifetime prevalence ranging from 10.9 to 62.8 per 1000. The lifetime prevalence rates of epilepsy (recurrent unprovoked seizures) ranged from 5.8 to 15.5 per 1000. Lifetime prevalence rates of neonatal, all provoked and all unprovoked seizures, as well as estimates of the prevalence of active epilepsy, are also reported. Author-abstract.

AB Technology is only one solution to a complex problem.

Speech-language pathologists need to evaluate and apply existing service delivery systems carefully. We also need to develop innovative and creative alternatives. Rather than continuing to fit our clients into the existing systems, we need to promote systems that more adequately meet their needs, regardless of barriers. Given the diversity of rural America, no single model or strategy is enough. A model that may work in one remote/rural island or desert area may not work in a rural farm community. At times a combination model may be the most efficient and effective means for serving our clients. The problems in service delivery to the *underserved* populations in remote/rural areas can be solved. The solutions require flexibility and adaptability of traditional, alternate, and innovative service delivery models, depending on the unique characteristics of the community. Author-abstract.

 AB Recent studies indicate a great need for dental treatment and
 preventive services in dentally *underserved* communities in southern
 Africa. Geographic inaccessibility, limited financial resources, and
 a maldistribution of dental personnel are the main barriers to oral
 health care. This project describes the evolution and utilization of
 a unique, purpose-built, mobile dental unit (MDU). From a compact 2
 x 2.5 meter box trailer, an enclosed area of 8 x 9 meters is formed
 by deploying a cover system housed on top of the trailer. Once
 deployed, the unit becomes four fully equipped dental operatories and
 a combined waiting and educational area, with all-weather protection.
 Comprehensive care is provided by dental auxiliaries. The underlying
 philosophy of the service is based on the primary oral health care
 approach. To date, the MDU has visited a wide variety of rural and
 urban communities where several thousand patients have been examined
 and treated. Assessment of the MDU indicates that it is an effective
 and viable alternative oral health delivery system.

JT ARCHIVES OF INTERNAL MEDICINE.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB BACKGROUND--Long Island (NY) has the highest incidence of human immunodeficiency virus infection of any suburban area in the United States. Until 1988, however, no patient with the acquired immunodeficiency virus had been admitted to any one of the 61 Long Island nursing home facilities. METHODS--A 10-bed acquired immunodeficiency syndrome unit was established in a county-owned skilled nursing facility. Before implementation of the unit, all staff members underwent extensive training and education, and standard precautions against infection were emphasized. Meetings were held with current residents of the nursing home and their families to address their fears and concerns. The unit was staffed entirely on a volunteer basis. RESULTS--The unit was opened in October 1990, and 16 patients have been admitted since that time. The geriatric and human immunodeficiency virus-positive patients interact well, and no complaints have been received from the geriatric patients or their families. No known breaches in infection control policies have occurred. There have been no problems in staff recruitment. CONCLUSIONS--Long-term care for patients with human

immunodeficiency virus in an existing nursing home facility is an achievable goal. Author-abstract.

- PT JOURNAL-ARTICLE (ART).
- LG English (EN).
- AB The paper is an attempt to analyse the pattern of cross-boundary flows to maternity clinics. The question is whether the expectations of expectant mothers who often travel long distances in order to give birth can be (i) explained by the lack of adequate levels of care in the out-flow areas, and (ii) justified in terms of birth outcomes. Infant mortality is used as a measure of the effectiveness of medical care. The results show that maternal mobility is indeed the result of inadequate provision of services. However, regional variations in infant mortality do not relate to availability of medical care. Mortality rates among infants born in the areas with net outflow of births are lower than the national average, while better-equipped areas experience higher infant mortality rates. Moreover, expectant mothers that move to Athens and Salonica (the main receiving areas) from the net outflow areas seem to face worst survival chances for their babies than those who stay. The nature of data does not permit control for risk factors and obstetric histories. However, it is argued that the sheer scale of maternal mobility and infant mortality differentials revealed in the paper imply that the possibility that moving itself significantly increases the risk of infant mortality should be looked at more carefully. The paper recommends the introduction of health policy initiatives in provincial Greece, aimed at increasing availability, improving standards and restoring public confidence to locally available medical services. The standards of care in maternity clinics should also be subject to audit mechanisms.

It is finally necessary that maternal mobility is confined to cases for which good medical reasons exist. Author-abstract.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Oklahoma physicians in three specialty areas (ob/gyn, family practice, and general practice) were surveyed in regard to their practice of obstetrics. The 611 physicians who responded included a representative sample in regard to county of practice, rural vs

urban, age, degree (DO & MD), specialty, and type of practice. Respondents accounted for 51% of the total 1989 births in Oklahoma during calendar year 1989. The vast majority (greater than 90%) of respondents report that they normally provide delivery services and prenatal care in combination. Cesarean sections are performed by almost all ob/gyns (97.6%), more than half of the family practitioners (56.5%), and a very few general practitioners (18.9%). Half of all physicians responding have made changes in their obstetric practice in the last 3 years. The most common changes are: reducing care of *medically* high risk, uninsured, and/or Medicaid patients. The most important reasons for these changes are: fear of obstetric malpractice suits, inconvenience of obstetrics and excessive professional liability insurance premiums. Specific reasons for reducing care to *medically* high risk patients were reported to be: increased medical legal liability, belief that high risk patients should be cared for by specialists, and lack of Medicaid reimbursement for diagnostic services. Almost 90% of the physicians responding to the survey are required to carry a minimum amount of professional liability insurance by the hospital where they practice with the most frequently stated amount being \$1,000,000. Current average "global fees" reported by the respondents were \$1,202 for a spontaneous vaginal delivery and \$1,543 for a cesarean delivery.(ABSTRACT TRUNCATED AT 250 WORDS). Author-abstract.

 AB Many users consider telemedicine a partial solution to problems of delivering health care to remote areas or areas *underserved* by clinicians. Current telemedical technology benefits from recent developments such as the decreased cost and improved quality of the coder-decoder (codec) equipment used in interactive digital video systems and the expansion of fiber-optic cable networks. The authors outline some pioneering telemedicine programs of the 1960s and 1970s and describe two recently activated systems in Texas. One network, serving the western two-fifths of the state, links faculty members from four campuses of Texas Tech University Health Sciences Center with almost 40 rural communities. The other connects the state hospital and three other facilities in Austin with four health care sites in the town of Giddings, 65 miles away. Besides serving patients, the systems provide continuing medical education and support to reduce the isolation of rural health care professionals. Primary goals include evaluation and certification of telemedical training and analysis of the cost feasibility of telemedical services. Author-abstract. 39 Refs.

 AB The 5-year survival of cancer of the breast in socioeconomically disadvantaged women is much too low because treatment is given for late stage disease. A screening mammography program at primary-care

facilities for *medically* *underserved* women has markedly increased in situ and local stage of disease and decreased distant disease. This has produced an estimated 50% decrease in mortality and a significant decrease in treatment costs. Unacceptable delay from positive mammogram to biopsy and pathologic diagnosis remained, so a one-stop breast center was established to perform breast physical examination, screening mammography, biopsy, and pathologic interpretation at one site on one visit for optimal cost-effectiveness. JT ACADEMIC MEDICINE.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Jefferson Medical College has developed a program to successfully meet the goal of teaching ambulatory care to all medical students, by providing each of its 223 third-year students with a required six-week clerkship in family medicine. The structured clerkship takes place at one of seven residency-based family practice centers, is supplemented by a formal curriculum, and is based on the active clinical involvement of caring for patients under full-time family medicine faculty supervision. This clerkship has been in existence for 16 years, and has added over 400,000 student-patient encounters to the clinical education of over 3,500 students. Student evaluations of the clerkship have rated it the highest of the six required core clerkships at Jefferson. In addition, over 16% of Jefferson graduates have entered family medicine residency training programs, a rate higher than that of any other school in the northeastern United States, and significantly higher than the average for all U.S. medical schools (12%). Jefferson's experience suggests that ambulatory care can be taught as a core component of the clinical education of all medical students. To be successful, however, strong institutional support, a structured curriculum, an adequate number of patients, a dedicated faculty, a sufficient number of training sites, an appropriate evaluation process, and significant financial support are all necessary. Author-abstract.

AB OBJECT: to determine whether the contracted general practices were situated in areas of greatest health need. METHOD: the health and equity index was used to determine the level of health need of the geographical location of the contracted practices. RESULTS: the health and equity index for the urban contracted practices showed a high level of health need. In the rural practices, the census area unit in which the practices were located showed a high level of health need, however when surrounding census area units were considered, they were located in areas of average health need. CONCLUSION: the general practice contract scheme was well targeted. Author-abstract.

JT FAMILY PLANNING PERSPECTIVES.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Abortion services are provided in hospitals, doctors' offices and various types of clinics, but about two-thirds of procedures are performed in specialized abortion clinics. While this system appears

to work well for most women, some women seeking abortion face obstacles related to distance, cost, harassment and special medical conditions. Nine percent of nonhospital abortion patients must travel more than 100 miles and 18 percent travel 50 to 100 miles for services. The average woman having a first-trimester nonhospital abortion paid \$251 in 1989. Fees were higher in facilities with small abortion caseloads. An abortion at 10 weeks' gestation in a hospital cost an average of \$1,757. Charges for abortions at 16 weeks averaged \$509 in abortion clinics, compared with \$1,539 in hospitals for curettage and \$2,246 for instillation procedures. Some women face other barriers: Only 43 percent of all abortion facilities offer services past 12 weeks, and 27-37 percent of nonhospital facilities say they do not treat patients who test positive for the human immunodeficiency virus (HIV), the virus that causes AIDS. Women who need special services such as an administration of Rh immunoglobulin, general anesthesia or HIV testing usually pay extra for these services. In addition, 85 percent of nonhospital facilities that serve 400 or more abortion patients a year reported some form of antiabortion harassment in 1988, most commonly picketing; there was virtually no change in this proportion between 1985 and 1988. Author-abstract.

 JT SOCIAL SCIENCE AND MEDICINE.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB The relation between current place of work (area of the country) and factors that might possibly represent doctors geographical attachments was studied in a sample of 322 Norwegian medical

specialists. Location of hospital residency, age and geographical origin of spouse were associated with current location. Geographical attachment seems to influence doctors' locational choices from start of medical school until the end of their residency. The probability that a doctor shall locate in peripheral areas may increase from less than 10% to more than 50% if the doctor has the residency training in the periphery. Hence, favoring entrance to medical schools of students from the *underserved* areas, and location of graduate and postgraduate medical training in the *underserved* areas, as far as it is feasible while still maintaining medical standards, is suggested by the study. Author-abstract.

TI Cross cultural communication to help physician assistants provide unbiased health care.

SO Public-Health-Rep. 1992 Jan-Feb. 107(1). P 113-5.

JT PUBLIC HEALTH REPORTS.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Teaching cross cultural communication typically involves instruction in differences between groups. As part of this course in cross cultural communication, six specific *underserved* population groups are introduced to students as a cultural experience. Additionally, instruction is provided to sensitize students to their personal biases and prejudices through videotaped mock interviews. The combination of instruction and experience forms a paradigm for teaching cross cultural communication in a way that has personal and immediate impact on faculty members and students. The model, "Differences + Discomforts = Discoveries," inhibits factionalizing and promotes depth of knowledge about *underserved* groups as well as personal awareness of prejudicial feelings. As a result, students learn techniques to provide unbiased health care to these, and other, populations. Author-abstract.

AB Through a nurse-midwifery service in a mixed urban and rural agricultural community, we compared maternal risk factors, prenatal care, labor and delivery, and adverse birth outcomes in low-income Mexican-American Hispanic, white (Caucasian), and Southeast Asian women--a three-way analysis rarely reported in the literature. Southeast Asian women were older and had more children. Hispanic women bore children at a younger age. Both Southeast Asians and Hispanics made fewer prenatal visits than did Caucasian women, and used less analgesia and anesthesia during delivery. The incidence of Cesarean section (7.7 percent) and low birthweight (5.9 percent) was compared to local, state, and national reference statistics. Prospective case-controlled studies and cost/benefit analyses of nurse-midwifery services could yield more definitive information. But until more precise data are collected for birth certificates, these studies will be difficult. Author-abstract.

 AB To study the effect that the decline in physicians in the National
 Health Service Corps (NHSC) pipeline will have on access to care for
 patients at sites to which NHSC physicians are assigned, a survey was
 sent to all NHSC physicians completing their obligated service in
 1989. Seventy-four (74) percent of the respondents believed that the
 decreased number of NHSC doctors in the pipeline would threaten the
 existence of their site and 52 percent reported that no doctors or
 clinic sites would be able to provide free or subsidized care if
 their NHSC site were forced to close. Of the physicians who stated
 that their NHSC patients would be able to find an alternative source
 of care, the most commonly cited (33 percent) alternative was the
 local hospital emergency room. We conclude that access to care for
 patients at NHSC sites will be seriously impaired by the decline in
 physicians in the NHSC pipeline. Author-abstract.

TI Relationship of infant mortality to the availability of obstetrical care in Indiana.
SO J-Fam-Pract. 1991 Dec. 33(6). P 609-13.
JT JOURNAL OF FAMILY PRACTICE.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB BACKGROUND. Projects that are currently under way in Indiana to improve access to obstetrical care have not addressed the availability of these services in nonmetropolitan areas. This study was designed to identify all physicians who were providing obstetrical services in every county throughout the state to determine if there is a correlation between the availability of these services and the infant mortality rate in nonmetropolitan counties. METHODS. A state-wide physician profile maintained by the Indiana Academy of Family Physicians was cross-referenced with a telephone survey of all hospitals in the state to identify those physicians providing obstetrical services within each county in Indiana. The number of physicians in each county was then compared with the number of births per year by mothers from that county to determine whether nonmetropolitan counties had sufficient physicians to provide

obstetrical services. Finally, these findings were compared with the most recent infant mortality rate for each nonmetropolitan county. RESULTS. A total of 610 family physicians, 311 obstetricians, and 75 general practitioners were providing obstetrical care in Indiana. There were 10 counties that did not have a physician who delivered babies practicing in that county. Thirty-two counties had more women who needed obstetrical care than the current number of physicians could serve. There was a negative correlation between physician availability and infant mortality in Indiana's nonmetropolitan counties ($r = -.38$; P less than .02). CONCLUSIONS. Access to care for pregnant patients is a major problem in rural Indiana and hampers Indiana's ability to reduce its current infant mortality rate.

AB Underutilization of community mental health services by minorities has been an ongoing concern in the field of mental health. Many agencies are mainstream and ethnocentric in their services to culturally diverse clients, resulting in color-blind treatment approaches. During the era of civil rights, the concept of difference was used to exclude groups of individuals, families, and communities from access to resources. However, ethnicity does matter and make a difference. This article will address the need for culturally relevant services for African-American clients with the dual diagnosis of substance abuse and mental illness. The intent is to provide mental health care providers with a culturally specific model that will render culturally relevant and culturally competent services to individuals from diverse cultural backgrounds.

AB Shortcomings in the organization of medical care for watch keepers lead to the imperfection in the selection of professionals, narrowing of specialized care volume under conditions of watch, differences in the pattern and frequency of applications for medical care, limitation in the access to medical care for the workers of the basic industries, misrepresentation of the essence of the follow-up method, morbidity assessment by applications for medical care and temporary disability. The detected differences require the development of a basically new organizational model for the provision of medical care to persons engaged in expeditionary-watch labour including mobile medical facilities (physician's ambulatory office, sanatorium department with a unit of psychophysiological relief) subordination of public health institutions to the single management cycle, introduction of a document such as "Healthbook of a watch-keeper", reorientation of northern health units to a certain volume of follow-up measures for securing continuity of observation during watch, inter-watch (home) periods, carrying out of medical examinations before and after the flights. AB There are only 350 child psychiatrists in Canada. It is therefore unrealistic to expect them to be able to provide sufficient direct treatment, even in small densely populated communities with abundant resources. Such expectations are even more unrealistic in underserved, sparsely populated areas. A review of the literature on psychiatric consultation in underserved areas is presented along with a description of the consultation process, taking advantage of the "multiplier effect." Some of the realities of mental health consultation in underserved areas are discussed, stressing the importance of consultation as a way of professional life. Some guidelines for the psychiatric consultant are outlined which would enhance the "multiplier effect". It is maintained that the training of psychiatric residents should include a supervised experience consulting in underserved areas. Finally, it is hoped that psychiatric training programs, funding bodies, hospitals, and agencies, will recognize the value of this use of psychiatric expertise. Author-abstract.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).
LG English (EN).
AB In the United States, the decades preceding the 1980s were
characterized by a decline in the incidence of tuberculosis. More
recently, the trend has undergone a significant reversal: Case rates
have been increasing by 3% to 6% annually. In 1990, more than 25,700
cases were reported to the Centers for Disease Control. In a sense,
tuberculosis is adapting to the '90s. The recent increase in its
incidence tends to affect populations with identifiable
characteristics. Among the most important of these groups are the
populations at high risk for infection by the human immunodeficiency
virus. The increase is also fueled by cases in populations that are
medically *underserved,* including foreign-born persons from
high-prevalence countries, persons with low incomes, and persons
living in long-term-care facilities--especially persons with previous
tuberculosis infection. Thus, factors such as homelessness, chronic
alcohol or drug abuse, malnutrition, and crowded living conditions
continue to favor development and transmission of disease. The
increase in the incidence of tuberculosis appears to be greatest when
subpopulations in such circumstances are also at high risk for HIV
infection. Complex issues in the diagnosis and treatment of
tuberculosis arise from these epidemiologic patterns. HIV infection
is associated with unusual presentations of tuberculosis. Thus, the
clinician must maintain a high index of suspicion for the disease in
the setting of HIV infection or risk of the infection. The
populations at greatest risk are likely to be mistrustful of the
medical system, making the long-term administration of potentially

toxic chemotherapy more difficult than it already is. Chronic substance abuse may complicate compliance and add further difficulties to the monitoring of chemotherapy. At the same time, the monitoring becomes even more important in the physician's effort to minimize adverse effects of the medications. Outbreaks of drug-resistant disease have recently occurred, complicating the selection of drugs and affecting the duration of treatment. Despite all of these problems, it is essential to establish a diagnosis and initiate treatment rapidly, both to arrest the disease process and to limit its transmission. Since Mycobacterium tuberculosis is spread to uninfected persons in aerosols generated by coughing or sneezing, the infectiousness of a patient with active disease can be related, at least in part, to the number of organisms seen on sputum smears. Initiation of therapy is followed by a rapid decline in infectivity. Author-abstract. 10 Refs.

AB The 1979/1989 patterns of General Dental Service provision in the Northern Region and its nine FPC/FHSA areas have been examined in relation to intraregional variations and assessed against the national average and other regions. Attention is drawn to the Northern Region's failure to reach national averages in a number of key measures of dental care, owing to the low numbers of practitioners working within the Region. It is clear that redistribution of dental manpower will not be generated under the present system. Alternatives are required if dentistry is to continue to be an essential part of a comprehensive health service

for all. Author-abstract.

JT PUBLIC HEALTH REPORTS.
PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).
LG English (EN).
AB There are approximately 600 Community and Migrant Health Centers (C/MHCs) providing preventive and primary health care services principally to *medically* *underserved* rural and urban areas across the United States. The need to develop geriatric programs within C/MHCs is clear. Less clear is how and under what circumstances a comprehensive geriatric program can be adequately financed. The Health Resources and Services Administration of the Public Health Service contracted with La Jolla Management Corporation and Duke University Center on Aging to identify successful techniques for obtaining funding by examining 10 "good practice" C/MHC geriatric programs. The results from this study indicated that effective techniques included using a variety of funding sources, maintaining accurate cost-per-user information, developing a marketing strategy and user incentives, collaborating with the area agency on aging and other community organizations, and developing special services for the elderly. Developing cost-per-user information allowed for identifying appropriate "drawing card" services, negotiating sound reimbursement rates and contracts with other providers, and assessing the financial impact of changing service mixes. A marketing strategy was used to enhance the ability of the centers to provide a comprehensive package of services. Collaboration with the area agency on aging and other community organizations and volunteers in the aging network was found to help establish referral networks and subsequently increase the number of elderly patients served. Finally, development of special services for the elderly, such as

adult day care, case management, and health education, was found to increase program visibility, opportunities to work with the network of services for the aging, and clinical utilization.

LG English (EN).

AB In some parts of Dade County, Florida, perinatal mortality rates have revealed serious problems in the delivery of health care to poor pregnant women. From 1982-1985, the reported perinatal mortality rates varied from 32-36 per 1000 live births, more than double the national average. Under the leadership of the Primary Health Care Consortium of Dade County (a federation of community health centers and other primary care providers), National Health Service Corps obstetricians and pediatricians served inner-city, *medically* needy patients as part of a coordinated perinatal plan from 1987-1989. Data on fetal and neonatal deaths, collected from census tracts adjacent to the community health centers, were used to study the

impact of Corps obstetrician and pediatrician placement. The respective perinatal mortality rates were compared with those of 1986 as historic controls. Within a year, the overall perinatal mortality rate was reduced by 45%. As a result, an estimated 320 lives were saved between 1987-1989. This public health achievement represents a measurable impact due to assignment of National Health Service Corps physicians and can be used as a working model to reduce perinatal mortality in *medically* *underserved* communities in the United States. Author-abstract.

LG English (EN).
AB The worldwide pandemic of acquired immunodeficiency syndrome (AIDS)
has the potential to cause catastrophic medical and social effects
that will influence world health well into the 21st century. The

causative agent, a lentiretrovirus called human immunodeficiency virus (HIV-1), is spread by intimate exposure to blood and bodily fluids through sexual, parenteral, and mother-to-infant exposure. The natural history from exposure to disease has a median incubation period of 8-10 years and is characterized by progressive depletion of CD-4 positive T lymphocytes as well as effects on other immune and central nervous system cell populations. The World Health Organization (WHO) estimates that between 8 and 10 million persons are currently infected with the virus worldwide, with 8 to 10 times this level projected by some estimates into the 21st century. Recent leveling off of AIDS incidence in the U.S. appears to represent the positive benefits of antiretroviral therapy, and considerable benefit could be seen if such therapies were made more widely available to *medically* *underserved* populations. With prolonged survival, however, other long-term sequelae such as cancer and lymphoma may emerge as significant complications of prolonged immunodeficiency. Furthermore, the large pool of already infected persons and continued spread of the virus make the development of additional therapies and an effective anti-HIV vaccine priorities of medical research. Author-abstract. 54 Refs.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB There is an urgent need to reduce cancer mortality among black Americans and other minorities. Although much progress has been made, cancer statistics are not as positive for these groups and the *medically-underserved* populations. Getting Americans to change their behavior patterns--particularly with regard to cigarette smoking--is vitally important. In this regard, physicians and other health care professionals, as well as public and government officials, must speak out. Early detection of risk factors is also critical. Government

has an obligation to make Americans aware of how to reduce adverse health indicators and of making individuals responsible for their own life as well as for the lives of their family members.

AB The homage of 135 abandoned children in the city of Resita, south west Rumania, has been checked by a medical team from the University of Innsbruck for social, clinical and hyginical situation. The local government had applied for such an investigation. Most of the infections and other diseases are based on a dramatically bad hygienical situation. 52% of checked sera were HIV positiv by RIA and Western Blot, moreover 60% Hepatitis B antigen positiv. We assume a high rate of horizontal transmission of the HIV virus. One of the main clinical symptoms was maternal-deprivation syndrome, with an incidence of 80%. Consequences in personal policy of the homage as well as medical strategies have to follow. Author-abstract.

AB Before the political change took place in the autumn of 1989, there had hardly been any discussions in the former German Democratic Republic regarding the emergency situation in hospitals in respect of patient care (shortage of nurses, funds, and equipment). However, available analyses prove that many problems were already well known. Not only has the lack of nurses been a severe obstacle to humane care, but the fundamental material prerequisites have also been lacking. Comprehensive changes are imperative to create conditions in all hospitals that will ensure that the hospital staff can look after their patients with maximum efficiency and dispatch to promote

speedy patient recovery. Author-abstract.

AB Access to pregnancy-related care for women and their infants and to reproductive health services for adolescents are significant concerns to the American College of Obstetricians and Gynecologists (ACOG). Adolescent and young adult women are among those most likely to be uninsured and lack access to health care services. Adolescent pregnancy, low-birth weight, and infant mortality remain major national burdens. The ACOG has taken the position that quality health care should be accessible to all women. The ACOG recommendations regarding health services for adolescents and the ACOG Committee on Health Care for *Underserved* Women's statement of principles regarding universal access for pregnancy-related care, which includes the basic scope of benefits, the characteristics of the providers, and the organization of services are described.  AB One hundred and sixty four ENT patients were observed at the Kashima
 village hospital located on the remote, isolated islands (Islands of

Koshiki), Kagoshima prefecture, during two years of April 1987 to March 1989. They were composed of the following conditions; 1. Of the 164 individuals, 46 cases, showing 28.1% were admitted from the other inconvenient districts. 2. About a half of all the patients with acute infectious diseases might be treated by their home doctors. 3. The patients required operative care were contained in the individuals with chronic inflammatory diseases. 4. Most of the cases with acute otitis in summer were caused by naked diving to catch the fishes in these islands. 5. The incidence of the chronic ENT diseases such as perceptive hearing disturbances including the presbycusis, chronic otitis media, chronic sinusitis, and laryngopharyngeal paresthesia in order, were the same as one of the previous reports in the other remote isolated islands. All the general practitioners worked in the remote isolated islands should be necessary to have a special training of fundamental knowledges and clinical skills in otolaryngology. Author-abstract.

SO Fam-Plann-Perspect. 1991 Jan-Feb. 23(1). P 6-16.
JT FAMILY PLANNING PERSPECTIVES.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB An evaluation of the reproductive health programs of six diverse school-based clinics measured the impact of the clinics on sexual behavior and contraceptive use. All six clinics served low-income populations; at five of them, the great majority of the students served were black. An analysis of student visits by type of care given found that these clinics were not primarily family planning facilities; rather, they provided reproductive health care as one component of a comprehensive health program. Student survey data collected in the clinic schools and nearby comparison schools (four sites) or collected both before the clinic opened and two years later (two sites) indicated that the clinics neither hastened the onset of

sexual activity nor increased its frequency. The clinics had varying effects on contraceptive use. Providing contraceptives on site was not enough to significantly increase their use; in only one of the three sites that did so were students in the clinic school significantly more likely than students in the comparison school to have used birth control during last intercourse. However, condom use rose sharply at one clinic school that had a strong AIDS education program and was located in a community where AIDS was a salient issue. At another clinic school, where pregnancy prevention was a high priority and staff issued vouchers for contraceptives, the use of condoms and pills was significantly higher than in the comparison school. A third clinic school--which focused on high-risk youth, emphasized pregnancy prevention and dispensed birth control pills--recorded a significantly higher use of pills than its comparison school. Although the data suggest that the clinics probably prevented small numbers of pregnancies at some schools, none of the clinics had a statistically significant effect on school-wide pregnancy rates. Author-abstract.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB A systematic effort is underway to rationalize the planning of physician supply. This paper summarizes the current methodologies available and focuses on the attempts to determine the optimal psychiatrist-to-population ratio in Canada. The impact of several variables influencing this ratio is discussed. An outline of the correlation between target physician supply and requirements of future trainees is presented. While the relevant methodology is rapidly evolving, an improved process of data collection is urgently required. A number of challenges for our profession lay ahead, such

as the need for sensitive and reliable measures of the adequacy of psychiatrist and subspecialist supply and public issues arising from the poor geographic distribution of psychiatric manpower.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB About half the 6 million blind people in sub-Saharan Africa have surgically curable cataract. The available manpower and resources can only provide services for less than 10% of the new blind cataract patients each year, and little is being done for the estimated 3 million "cataract backlog". A serious limiting factor to the development of prevention of blindness programmes is lack of trained manpower. Despite an increase in the number of ophthalmologists trained in cataract surgery (which varies greatly from country to country), this number is not keeping pace with increased demand for eye-care services, especially in large rural populations. Initiatives that will help to overcome this dilemma are specific post-graduate courses in community ophthalmology in Africa, plans to develop a one-year diploma in ophthalmology course for English-speaking West African countries, and a proposal to upgrade a similar course in Zimbabwe. Additionally there is a need for the training of more ophthalmic assistants, cataract surgeons, and nurses in the diagnosis and management of common ophthalmic disorders. Experienced expatriate ophthalmologists also have an important role in the teaching of doctors and ophthalmic assistants how to select patients and carry out successful inexpensive cataract surgery with appropriate technology and limited facilities. TI Surplus or shortage? Unraveling the physician supply conundrum.

SO West-J-Med. 1991 Jan. 154(1). P 43-50.

JT WESTERN JOURNAL OF MEDICINE.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).

LG English (EN).

AB Although the supply of physicians in the United States has doubled during the past 20 years, there is still disagreement as to whether we currently have or should expect a significant surplus of physicians. The evidence suggests that despite the rapid expansion in the pool of available physicians, serious physician shortages persist for certain rural populations, ethnic and occupational groups, and other *medically* disadvantaged segments of the population. Medical students' declining interest in rural practice and primary care specialties suggests that problems of geographic and specialty maldistribution may worsen despite a rising population of physicians. It is unlikely that a significant physician surplus will develop unless there is a conscious attempt to limit the proportion of

national wealth expended on medical care. Pockets of shortage can be reduced by broadening the availability of health insurance, lessening large income disparities between different specialties, changing the way teaching institutions are reimbursed for their training costs, and supporting direct governmental service programs such as the National Health Service Corps. AB Millions of residents of the United States have difficulty obtaining health care. Barriers impeding access to care include poverty, physical unavailability of health care services, absence of health insurance, and physicians unwilling to care for uninsured patients. Many patients do not successfully use health services because of educational, cultural, and language barriers. A major access barrier is lack of health insurance. Over 30 million people in the United States have none, the so-called *medically* indigent. Among them are over 3 million people with neurologic disorders. They have additional barriers to overcome because often they cannot work, cannot drive, have difficulty using public transportation, and have major cognitive and communication impairments. Medical and governmental bodies are debating solutions to the health care access crisis. Physicians should actively participate in this national debate. Neurologists should address the special needs of patients with neurological disorders. Author-abstract.

 TI The historical development of western psychiatric practice in
 northern Nigeria--an uphill struggle.
 SO West-Afr-J-Med. 1990 Oct-Dec. 9(4). P 311-6.

JT WEST AFRICAN JOURNAL OF MEDICINE.

PT CURRENT-BIOG-OBIT (CBO). HISTORICAL-ARTICLE (HRT). JOURNAL-ARTICLE (ART).

LG English (EN).

AB The historical development of psychiatric services in what was Northern Nigeria is given. It started with the time when the only thing done for very psychotic patients was custodial in prisons. The appearance of many psychopharmacological agents after 2nd World War made possible the establishment of psychiatric units in general hospitals for the treatment of acute cases only. The arrival of Oshodi in 1961 led to the evolution of modern psychiatric services with the unit he started in Kaduna-Zaria at the apex of the services provided throughout the Northern States. The unit in Kaduna was to evolve into a University Teaching Department. It is still at the apex of psychiatric services of most of the ten Northern States. Some of the other erstwhile peripheral units have also metamorphosed into nuclei of the four younger University Teaching Units. From only one psychiatrist up to 1977, there are now 12 out of the just over 60 psychiatrists in the whole country, practicing in the Northern States. Relative mental health for the more than 50% of the 100 million people of Nigeria living in the Northern States by the year 2000 is very much in doubt unless something is done with dispatch. TI Health service resources as determinants of infant death in rural Bangladesh: an empirical study.

SO Soc-Sci-Med. 1991. 32(1). P 43-9.

JT SOCIAL SCIENCE AND MEDICINE.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Using empirical data collected from a rural area of Bangladesh, this paper examines the relative importance of availability of health care resources on infant death. Following many health care studies, this paper hypothesizes that the likelihood of infant death is a function of accessibility to different types of health facilities and personnel. Both univariate and multivariate analyses of data indicate that the distance to a qualified physician of Western medicine exerts significant influence on infant deaths. Other variables considered are distance to Upazila Health Complex (UHC),

Family Welfare Center (FWC), and non-qualified doctors.

AB It is evident that the setting up of efficient psychiatric services
today is not feasible without elaborating serious theoretical
concepts. In the authors' opinion, the method which would make it
possible to rapidly design the system of psychiatric services for any
region on the basis of the data on its geography, population and
resources rather than concrete universal services is to be the final
product of the theory of psychiatric services. To design such a
method, it is necessary to explore a number of important problems of
the epidemiological and ++medico-demographic character. The authors
provide a list of the studies to be carried out according to the

indicated directions as well as of the problems to be solved within the framework of the investigations of the models proper of psychiatric services. Author-abstract.

 AB Diagnosis and treatment of cancers at advanced stages have
 contributed to a significantly lower survival rate among individuals
 of low socioeconomic status compared with those in higher brackets.
 In an effort to increase the accessibility and acceptability of
 cancer screening among such individuals in Dade County, Florida, the
 Cancer Control Division of the Sylvester Comprehensive Cancer Center
 at the University of Miami School of Medicine initiated a pilot early
 detection program in 1987. The program initially provided breast
 cancer screening for women, aged 40 and older, who attended ten
 community health care centers located in low-income neighborhoods.
 With the selection of Miami by the American Cancer Society as one of
 three sites for conducting a screening demonstration project for the
 socioeconomically disadvantaged, this program has recently been
 expanded to include pelvic screening for women, aged 40 and older,
 and prostate screening for men, aged 65 and older. Author-abstract.

 JT PUBLIC HEALTH REPORTS.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB Strategies designed to meet the health care needs of Americans should
 include the issues of access as well as financing. And primary care
 and clinical preventive services should receive as much national
 attention as acute care and long-term care. The public health system
 at the Federal, State, and local levels with its mandate to assure
 conditions in which people can be healthy must also be incorporated
 into the national debate. Publicly funded infrastructures for
 delivering primary health care have become a significant element of
 assuring access at the community level. This paper examines the
 expanding role of public health in assuring access to the delivery of
 primary health care and clinical preventive services to vulnerable
 populations within the larger issue of who should have access to care
 and how it should be made available. Special attention is paid to
 the part played by the Health Resources and Services Administration
 (HRSA) of the Public Health Service, which, in the Federal fiscal
 year that began on October 1, 1989, administered some \$1.8 billion
 worth of programs for health care of targeted populations and for the
 support of training in the health professions. Author-abstract.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB As the Federal agency that provides leadership in expanding access to primary health care, the Health Resources and Services Administration (HRSA) manages some 50 programs directed toward the delivery of services and strengthening the base of national health resources. An enabling element of the agency's strategy is the expansion of partnerships with national associations, private foundations, and other entities that share a concern for the health care of the *medically* *underserved.* Cooperative efforts with national organizations are intended to promote the integration of public and private resources and encourage adoption of efficient approaches to organizing and financing health care. Medical education in the primary care specialties, State programs for women and children, involvement of managed care organizations with low-income populations, and programs concerning the uninsured are the foci of some of these collaborative relationships. Author-abstract.

- AB An analysis of reported state and federal adjudication from 1950 through 1989 was undertaken to identify trends in litigation involving medical students and undergraduate medical education. Of the 110 cited judicial decisions during that time, 59 (54%) involved disputes over financing medical education; 43 (73%) were litigated since 1985. This dramatic increase arises primarily from challenges to National Health Service Corps obligations and from attempts to discharge or reorganize debt under the Bankruptcy Code. Medical school graduates enjoyed very little success in these cases. Analysis of court decisions points to a need for informed counseling for medical students, particularly as to the consequences of timing in default on service obligations and of incurring loans under the Health Education Assistance Loan (HEAL) program as opposed to other loan sources. The growing educational debt of today's medical students foreshadows continued litigation in this area. Author-abstract.

AB Within the United States Public Health Service, the programs of the Bureau of Health Care Delivery and Assistance have played an important role in improving access to primary care services in rural America. In part, this has been accomplished through the administration of grants to assist in establishing systems of care and the assignment of National Health Service Corps (NHSC) health professionals. From a peak of over 1,600 NHSC-obligated scholarship recipients available for service in 1985, the number of available obligated practitioners has decreased to around 120 in 1990. A main focus of the NHSC has, therefore, necessarily changed from the placement of obligated health professionals to the recruitment of volunteers and increased emphasis on the retention of current providers. The systems of care that have been most successful in their retention efforts have been: group practices, composed of a nucleus of individuals who had been at the site for three to five years; community-oriented, utilizing non-physician providers as part of the delivery team; and those committed to continued provider education. The NHSC has initiated programs to help increase the likelihood that medical students will choose a primary care career and spend all or part of that career serving those most in need. These programs include the National Medical Association Minority Mentor Network, the American Medical Student Association Health Promotion/Disease Prevention Program, the Commissioned Officer Student Training and Externship Program, and the American Academy of Family Physicians Residency Advocate Program. To meet the future needs for access to care in rural America, partnerships with academic centers must be enhanced and expanded. Author-abstract.

AB Rural health care can thrive if innovative tactics are used. Four assumptions can influence how health care occurs in rural areas. One assumption is to view the world in a "both/and" view of human phenomena. Second is to recognize that competition is a dominant mode; and that using integrative/collaborative solutions could enhance all health care. Cultural ethnocentricity and professional ethnocentricity, the third assumption, are counterproductive. This is especially true in rural America. The fourth assumption, one can only accomplish what one can imagine, sets an infinite range of possibilities for rural health care. Education must change to incorporate a commitment to collaboration and to integrative, innovative solutions to problems. Author-abstract.

SO Acad-Med. 1990 Dec. 65(12 Suppl). P S32-40.

JT ACADEMIC MEDICINE.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Solo practice is the dominant mode of rural medical care delivery. At the same time, it is the most likely not to succeed, because the solo physician is choosing to leave the rural community. Group family practice is the most stable form of rural practice, is acceptable, and is sought by the majority of family practice residents seeking to establish new practices. Characteristics of successful rural practices include group practice, retention of the same health care providers for more than three years, a community-oriented focus, integration of non-M.D. health care providers, and a commitment to education within the practice. Academic medical centers with area health education centers (AHECs) should consider developing expanded AHECs to provide the education, planning, consultation, and expertise now needed by rural communities. Academic medical centers without AHECs should consider creating offices of rural health to provide the education, planning, consultation, and expertise needed in rural communities. Author-abstract.

 AB A number of efforts can be attempted in rural medical education initiatives in recruitment, socialization, curricular reform, and community technical assistance. Further work is needed in identifying strategies that are most appropriate and cost effective in different states and regions that may have different situations and needs. Careful consideration needs to be given to reasons why such ideas have not moved beyond the demonstration stage over the past 20 years; it is suggested that without substantial reform of payment systems favoring rural and primary care, educational reform will have marginal effectiveness and remain at the demonstration level.  AB Although legislators have intermittently focused their attention on physician manpower issues, the needs of rural America for physicians remain unmet. These needs will not be met unless there is an adequate supply of physicians receptive to and appropriately trained for the challenges and opportunities of practice in a rural community. A declining interest by matriculating and graduating medical students in primary care practice makes it problematic that the needs of rural America can be met in the near future unless

medical schools attempt to reverse the trends in medical students' specialty choices. In October 1989, the University of Washington School of Medicine conducted a working conference on physician manpower issues facing rural communities in Washington, Alaska, Montana, and Idaho. The discussions and conclusions of this conference about increasing the percentage of graduates entering rural practice apply to other regions of the country, and this paper summarizes the conference's recommendations. JT BAILLIERES CLINICAL OBSTETRICS AND GYNAECOLOGY.
PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).
LG English (EN).
AB Antenatal care providers vary from one country to another. In Europe, most of the care is provided by obstetricians in some countries, while the role of midwives is important in other

countries. Many women are attended by general practitioners in Canada and, to a lesser extent, in the US. Involvement of traditional birth attendants in antenatal care in more than 5% of the pregnancies has been reported in Guatemala, Honduras and Mexico only. Several indicators may be used to measure the utilization of antenatal care: the percentage of women receiving care, timing of the first visit, proportion of women receiving late or no care, number of visits and indexes of adequacy of antenatal care. Recent world data are provided. The percentage of women receiving antenatal care is higher than 90% in many countries, including some developing countries. However, the proportion of women with late or no care is increasing in the US. Women of low sociodemographic status are at high risk of having inadequate care. Financial barriers play a major role. Inadequate system capacity, distance, long waiting time, lack of child care and differences in culture, attitude and knowledge are other important barriers. Improving the services and outreach of non-participating women may both increase the utilization of antenatal care. Overutilization should also be a matter of concern. It could be better addressed by decreasing the recommended number of visits than by requesting payment of a part of the costs by the users. Author-abstract. 94 Refs.

LG English (EN).
AB This first, extensive, facility-based study of health services utilization in central, southern and western Ethiopia reveals steep distance decay gradients and underutilization of rural health services, the result of numerous geographical, socioeconomic, cultural and facility-based barriers. Out-patients statistics of 280,656 first-visit polyclinic patients in 8 hospitals, 8 health centres and 9 health stations in 7 administrative regions and of 10,885 sick children, 7767 antenatal attendants, 902 family planning acceptors, 275 vaccinated children and mothers and 1066 free patients, as well as in-patient statistics of 11,221 patients in 5 hospitals were analysed to determine catchment areas and utilization rates. On the average, 46% of the polyclinic patients were residents of the same town or village, 39% of the same awraja (district) and 5% of other administrative regions. Sick children, family planning attendants, free patients and in-patients lived relatively nearer to health facilities than polyclinic out-patients. Interviews with polyclinic out-patients showed that type and cost of transportation, type of illness, patient preferences, socioeconomic status of patients and referral patterns were important factors in utilization.

Aggregation of all available health services data indicates that whereas some towns approach the targeted 2.5 per capita patient visits per year, coverage of the rural population is relatively low. Suggestions are made on how to overcome the problem of underutilization of rural health stations and to improve the health services information system. Author-abstract.

 AB A mobile child and youth psychiatric service is presented that concerned with the mental health care of a county with a population of 239,000 inhabitants. This kind of service was conceived especially to meet the demands of rural regions which are high, as empirical investigations about administrative and real prevalence have shown. The hypothesis that child and youth psychiatric or other specialized institutions create demands not normally existing, could be refuted. The service proved to be an efficient model for mental health care in rural regions so that it can be looked upon--especially in areas which are not sufficiently provided with child psychiatric institutions--as a fully valid alternative to other kinds of mental health services. Still, there is the problem of financing, which is not yet completely solved. A standardized regulation for the whole Federal Republic is suggested with the participation of the health insurance funds. Author-abstract.

SO Probl-Tuberk. 1990. (1). P 12-6.

JT PROBLEMY TUBERKULEZA.

PT JOURNAL-ARTICLE (ART).

LG Russian (RS).

AB Though in the Far North areas there is a decrease in the epidemic causes of tuberculosis, one can observe a greater role of negative social and sanitary factors influencing its morbidity. In the pattern of factors predisposing to newly diagnosed cases of the disease, unsatisfactory housing and living conditions as well as unqualified physical labour performed under unfavourable production and extreme climatic conditions, which are often combined with hazardous habits and concomitant diseases, are becoming more common. Higher tuberculosis morbidity among the aboriginal population with lower rates of their contamination are directly related to the level of their social and sanitary conditions, traditional way of life, occupational activities and disadvantages in the social development of the areas of their preferential habitation. In this connection, while taking further steps against tuberculosis in the Far North areas, it seems necessary to intensify social and preventive measures as well as antituberculous care of the groups which are influenced by clearly negative social and sanitary factors. Author-abstract.

JT JOURNAL OF THE NATIONAL MEDICAL ASSOCIATION.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB The NMA has long had the participation and leadership of those in
primary care and those who practice in *medically* *underserved* or
medically indigent areas. We, therefore, are most supportive of the
objectives and goals you have presented. We have offered suggestions
to strengthen your "White Paper" by emphasizing the vital nature of
the current and future role of primary health care delivery; by
stating the effects that changes in physician reimbursement,

especially utilizing the Relative Value Scale, will have on the expectations of those who are considering primary care; by continuing to offer scholarship assistance and loan forgiveness to those who are willing to commit during their medical education to a primary care career through the NHSC; by making a priority the effort to recruit older physicians by providing well-defined incentives, including liability relief; and by emphasizing the continued recruitment, retention, and encouragement of minority and disadvantaged applicants entering health care careers and stressing the support they must receive to be able to afford to practice in *underserved* areas. The National Medical Association welcomes the chance to undertake any collaborative efforts which may aid our mutual missions. Therefore, we are willing to assist you in helping to solve the critical need for primary care physicians in *medically* *underserved* communities. Author-abstract.

SO J-Sch-Health. 1990 Mar. 60(3). P 87-91.

JT JOURNAL OF SCHOOL HEALTH.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Resolution 162, which was adopted at the 1987 Annual Meeting by the Board of Trustees, called on the American Medical Association to study the efficacy of school-based health clinics. Recent data show that a significant number of school-aged youth are in need of an adequate source of health care. School-based health programs constitute a promising avenue for providing health services to adolescents, particularly in *medically* *underserved* areas. Although there are insufficient data to support universal establishment of school-based health programs, small-scale studies suggest that such programs are a viable means to increase access to health care for youth. Author-abstract.

 urban black community: a conceptual model.
 SO Health-Educ. 1989 Dec. 20(5). P 56-60.
 JT HEALTH EDUCATION.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB The community organization and development process is not new and has
 its roots in social action ideology from the 1960s. The difference
 between the 1960s and the 1990s is in bringing together of target
 community consumers with representatives of private and public sector
 resources (with consumers in the majority), to form a community
 coalition board. This community coalition board must make policy
 decisions. Combining these community organizers and development
 techniques with the mission of health promotion is a viable
 methodology for addressing the needs of *medically* *underserved* and
 unserved communities. The approach is a multifactorial one, as
 illustrated in Figure 1. The Health Promotion Resource Center at
 Morehouse School of Medicine seeks to combine the ideology of
 community organization and development with culturally sensitive and
 linguistically appropriate health promotion curriculum materials and
 intervention strategies. Within the HPRC lies the Statewide
 Coordinating Center for Georgia which has been funded by the Henry J.
 Kaiser Family Foundation. Its mandate is to assist minority and poor
 communities in Georgia in developing community-based health promotion
 initiatives which address the areas of cancer, cardiovascular
 disease, adolescent pregnancy, substance abuse, and violence and
 unintentional injury. Our strategy in carrying out this mandate is
 the community organization and development model described in this
 article. Author-abstract.

JT SOUTH DAKOTA JOURNAL OF MEDICINE.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Physician numbers and placement continue to be major health delivery concerns in the rural state of South Dakota. This study of four-year graduates (1977-1985) of the South Dakota School of Medicine looks at current factors affecting physician placement and compares placement and location selection factors to a previous study of graduates of the medical school when it was a two-year program (1969-1973).

Factors influencing physicians locating in South Dakota were:

closeness to their home town and or spouses' home town, residency training in small towns, payment of educational loans, medical school clerkships, time of decision, etc. Factors influencing physicians locating in rural communities (less than 5,000) were: growing up in small communities, residency training in small communities, early location decisions, payment of loans, and high medical need.

PT HISTORICAL-ARTICLE (HRT). JOURNAL-ARTICLE (ART).

LG German (GE).

AB An enormous transformation of health care delivery to the proper Bernese Oberland took place because of improvements in the transportation system, a raising number of practitioners, the nearly complete financial coverage of the population for the cost of this improved health care system and finally the raising awareness of the population for modern medicine. Expectations not only towards an increased life-expectancy but towards improved quality of life developed stormingly. According to valleys the changes in population, prominent types of physicians, birth, death and epidemics are reviewed. Financial and transportation-related problems, developments in care at home and outsiders are briefly highlighted.

AB A general deterioration is occurring in the quality of life of rural Americans, and it is affecting the quality of health and mental health service delivery. About 24% of the U.S. population lives in nonmetropolitan areas where the citizens are older, less well educated, have lower incomes, and are more homogeneous in terms of race and ethnicity. Medicare and private insurance discriminate against rural services in their reimbursement policies, and there is a shortage of health personnel in rural areas. However, there has been renewed congressional action to meet rural needs. Both the House and Senate have established rural caucuses, and an Office of Rural Health Policy has been established in the federal executive branch. Legislative successes were achieved between 1985 and 1988. Rural initiatives will provide psychology with unique opportunities in the next several years. Author-abstract.

JT JOURNAL OF THE MEDICAL ASSOCIATION OF GEORGIA.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Physician supply in Georgia must be considered an urgent issue. Several important points must be recognized and addressed. The lowest physicians rates are in the more rural county population groupings. The only county population grouping with a surplus of physicians is in the over 150,000 population. The majority of physicians are concentrated in the metropolitan counties. Sixteen percent of all physicians practice in the 134 counties having less than 50,000 population. The majority of physicians are in primary care specialties. Family practice is the most dominant specialty in rural areas. By the year 2000, Georgia can expect to add 5,600 physicians due to growth. By the year 2000, Georgia can expect to lose 2,600 physicians due to retirement. Family practitioners are the most uniformly distributed of the specialties examined. They are also the specialty most needed. The average age of Georgia physicians is 46. General surgeons are in the oldest average age group (50), whereas internists are in the youngest (44). Older physicians are concentrated in the more rural areas. A significant number of all physicians are over age 55. The majority of these will be retired by the year 2000. Physicians over age 65 represent 9.2% of all physicians from the survey. In Georgia, 13.6% of all physicians were Foreign Medical School Graduates. They tend to locate their practices in *medically* *underserved* areas. The specialty choices most frequently favored by FMGs are: pediatrics, internal

medicine, family practice, and obstetrics/gynecology. A total of 71.2% of all physicians accept Medicare patients; 83.8% accept Medicare patients. Ninety-two percent of all obstetricians accept obstetric patients, but this participation is threatened by problems with malpractice insurance. Author-abstract.

TI Extradural haemorrhage: strategies for management in remote places.

SO Injury. 1988 Sep. 19(5). P 307-12.

JT INJURY.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB A study of 109 cases of extradural haemorrhage (EDH) treated in South Australia over a period of 7 years showed that 35 cases (32.1 per cent) presented in country areas at considerable distances from a neurosurgical service: the mortality in these country cases was 22.9 per cent, comparing unfavourably with a mortality of 12.2 per cent in metropolitan cases. The country series contained a disproportionately large number of cases with multiple intracranial haemorrhages, which are known to have a poorer outcome; when these cases were excluded, the rural mortality (12.5 per cent) was only a little over the metropolitan mortality (9.7 per cent). These data suggest that it is possible to manage extradural haemorrhages successfully even in places remote from a neurosurgical centre, if communications and air transport are used effectively. However, it was found that emergency operations carried out in country hospitals were sometimes inadequate or done too late. Medical retrieval teams based on city hospitals were sent out on 15 occasions, either to assist a general surgeon to complete an emergency operation, or to provide intensive care during transfer to a neurosurgical unit. Osmotherapy (mannitol and/or frusemide) has been useful in gaining time for transfer; the choice between immediate operation and transfer may be difficult, and decisions should take transfer time, clinical state and rate of deterioration into account.

AB The University of British Columbia Child and Family Psychiatry
Outpatient Department has, since 1974, conducted intensive child
psychiatry assessments of patients referred from outlying areas. The
marathon assessment, as we have called it, requires up to three days
during which clinic staff conduct interviews with the referred
patient and family, and perform specific investigations as necessary.
By the end of the third day, the clinic team presents its findings
and recommendations to the family, and by phone and letter to the
referral source with arrangement for follow-up by physicians and/or
mental health clinics in the patient's geographic region. The
marathon evaluation has proven a worthy alternative to outreach
visits by a travelling child psychiatrist and to inpatient hospital
evaluations. The reasons for the advantages are enumerated.

TI Evaluation of a primary health care program for the poor.
SO J-Community-Health. 1989 Summer. 14(2). P 107-20.
JT JOURNAL OF COMMUNITY HEALTH.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB This paper examines the success in implementing a major program
involving a partnership between public and private providers to
deliver primary health care services to the poor. In 1985, the 69th
Texas Legislature passed the Primary Health Care Services Act,
authorizing the Texas Department of Health to contract for or
directly provide primary health care services in those parts of the

state that are *medically* *underserved* and have large numbers of people in poverty. This paper evaluates the potential impact of the projects with respect to access and cost. The study revealed that the basic concept of allowing local public and private providers to develop projects reflecting their community's unique needs and resources was successful. The approach lead to a wide variety of different types of projects, but the basic goals and activities of the projects are consistent with the legislation. The evaluation identified three major program areas that could be improved: (1) patient monitoring and follow-up to ensure the accessibility of the priority primary care services, (2) the need for the development of projects in other high need areas of the state, and (3) greater efficiency in service delivery. Author-abstract.

AB Physicians seem to prefer to practice in communities where there is already an adequate number of physicians, rather than in *underserved* rural areas. Virtually all studies examining this problem base their data on subjects who are already within or beyond the medical education process. Thus, such studies may obscure the degree to which practice site preferences are a result of the medical education selection process, or to what degree they were present in the premedical student population. Medical school applicants were surveyed about their intended practice site choices, as well as a number of characteristics thought to be correlated with intended practice sites. Eleven characteristics were found to be associated with intended practice sites. A disproportionately large number of applicants intended to practice in mid-size communities, a disproportionately low number of applicants in rural areas. There was no statistically significant difference in the acceptance rates of applicants who planned to practice in rural areas and those who did not. Author-abstract.

AB The National Area Health Education Center (AHEC) Program and the family practice specialty were both created around 1970, in part to help meet the health care needs of *medically* *underserved* populations.

Because these two entities share the common goal of alleviating physician shortages in rural areas, a study was conducted to determine the nature and extent of their interaction. Questionnaires were mailed to all AHEC projects and all nonmilitary family practice residency programs. Response rates were 100% and 79%, respectively. Elective rural rotations (usually preceptorships) are offered by 135 (49%) residencies, but only 84 (31%) require them. Fourteen (64%) AHEC projects interact with family practice residencies; however, only 9% (15/167) of the programs in those states utilize AHEC resources. The authors conclude that additional rural rotations could be offered to family practice residents by taking advantage of under-utilized resources of the National AHEC Program.

AB Proceeding from the analysis of the organization of reception of
patients in 4 city polyclinics having 104 therapeutic sectors, the
study demonstrated decrease of the amount and breach of continuity of
medical care rendered to the residents of the sectors where doctors
were absent during the reception. It was proposed to appraise and
monitor the work of sector physicians during their reception of
patients through a complex indicator of intensity of consultation
rates at other medical sectors. The introduced system of extra
payment of physicians and paramedical staff for reception of patients
from other sectors where the sector physician was absent could raise
continuity of care and eliminate patients' complaints and discontent
of medical workers. Author-abstract.

 AB Graduates of four rural and four urban family practice programs were
 interviewed to determine the nature of their practices and the
 factors that had influenced their practice location decisions. All
 programs gave residents substantial experience providing continuity
 of care for *underserved* populations. Of the 158 physicians surveyed,
 58 (46%) were working in areas designated as *underserved.* The
 percentage of physicians in *underserved* areas was higher than that
 reported in other studies and was much higher than would be expected
 if practice sites were selected on the basis of population
 distribution alone. Notable differences in personal and practice
 characteristics were found between the physicians who chose to work
 in *underserved* areas and those who did not and between those who
 established practices in rural and in urban *underserved* areas.

 JT INJURY.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB There is a need to put more emphasis on primary surgical care centred
 on provincial and district hospitals in the developing world using
 simple equipment which needs little maintenance and low running
 costs. The general duty doctors and paramedicals who are at the
 first point of contact with the patient, need practical on-site
 instruction in dealing with common surgical emergencies, of which
 injury forms a large part. To achieve this change in emphasis,

provision should be made for surgical trainees and experienced surgeons from the United Kingdom or else where to work in selected provincial and district hospitals where support services can be adequately provided. The experience they would gain, would in turn benefit their patients in the National Health Service. If this activity is to have any chance of success, the training and research potential must be recognized by the Royal Colleges as valid experience in higher surgical training programmes. The National Health Service and the Health Authorities must accept these periods overseas as integral parts of a career in the National Health Service. This would include provision for superannuation, encouraging proleptic appointments to consultant posts, and secondment or early retirement of Consultants. Funding should be sought from international and national agencies for a pilot project based on a direct link between a district hospital in this country and a selected district or provincial hospital in a developing country.(ABSTRACT TRUNCATED AT 250 WORDS). AB An extramural dental education experience which is a required component of the University of Florida College of Dentistry is described. The program, established in 1977, is conducted on a contractual basis between the college and the Lafayette-Suwannee Rural Health Corporation, Inc., the governing body of the Dental Center clinic located in the town of Mayo, Florida, which is 65 miles from the dental school. The program has brought high quality comprehensive dental care to a previously *underserved* population. Dental students are provided with experiences that enhance social sensitization, and that are perceived by them as a help in bridging

the gap between dental school and dental practice after graduation.
The program has made valued contributions to the education, research,
and service components of the dental school's mission.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Of cancer patients in Nigeria, 92% report at a late stage before
treatment. Those with tumours of the head and neck region in

particular, pose serious problems with management. Their advanced disease means that they are often inoperable and results of treatment by radiation are poor because the dose is limited to what the tissues can tolerate and also because the larger the tumour volume involved, the less the amount of radiation dose possible, so the response is poor. The problem is made worse by inadequate radiotherapy facilities. At the time of the study only one moderately equipped radiotherapy centre served the whole of Nigeria (with a population of 100 million) and neighbouring Ghana, Sierra-Leone and the Cameroons. There is usually a patient waiting list of about 3-4 months at any time, thus making prompt treatment impossible. These local problems and the search for an alternative approach led to this prospective study, which took place between 1980 and 1984. Two hundred and five adult patients with histologically proven, and locally advanced, epidermoid carcinoma in the head and neck region were given combination chemotherapy with Vincristine, Bleomycin and Methotrexate as the first line of management. There was a tumour regression rate of 68% (complete + partial), such that further treatment with surgery, radiotherapy, or a combination of both was then possible.

AB Resolution 162, which was adopted at the 1987 Annual Meeting by the Board of Trustees, called on the American Medical Association to study the efficacy of school-based health clinics. Recent data show that a significant number of school-aged youth are in need of an adequate source of health care. School-based health programs constitute a promising avenue for providing health services to adolescents, particularly in *medically* *underserved* areas. Although there are insufficient data to support universal establishment of school-based health programs, small-scale studies suggest that such programs are a viable means to increase access to health care for youth. AB The confluence of forces slowing the growth of the physician supply despite a continued shortage of primary care physicians, the encouragement of competitive medical practices that centralize resources in larger places, and the changing of the rural population's character to one of more dependence on medical care may bring on another "rural health crisis" in the decade ahead.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Health care costs and government cutbacks in Canadian training posts
have caused concerns about physician manpower. To determine the
present pediatric manpower situation a cross-country survey was

undertaken of all pediatricians and their practice patterns. Of the 2060 recipients of a questionnaire 5% were found to not be pediatricians. Of the remaining 1960, 69% returned a completed questionnaire. Overall, 70% of the pediatricians were men, although among those less than 35 years of age 49% were women. Across Canada 37% of the pediatricians practised primary care, 25% secondary care and 38% tertiary care. There were wide regional differences in practice patterns, with large numbers of primary care pediatricians in Winnipeg, Toronto, Ottawa and the province of Quebec; few pediatricians in the Maritimes and the remainder of western Canada practised primary care. Non-Canadian graduates accounted for 33% of the pediatricians and represented a considerable proportion of tertiary care pediatricians. Cutbacks in numbers of pediatric training positions and restrictions on immigration of foreign pediatricians may lead to unexpected deficiencies in the availability of some types of pediatric practitioners, especially those in tertiary care. Author-abstract.

 AB The purpose of this study was to assess changes in the
 physician-population ratio in non-SMSA Minnesota counties between
 1965 and 1985 using county specific data published by the American
 Medical Association. The physician-population ratio actually
 decreased by 2 per cent for primary care physicians and by 11 per
 cent for family practitioners in the non-SMSA counties. The large
 increase in the number of physicians in Minnesota has not translated
 into improved access to primary care physicians in Minnesota's rural
 areas. Author-abstract.

 JT NEW ZEALAND MEDICAL JOURNAL.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB Three hundred urban and 350 rural mothers were surveyed about their subjective perceptions of the availability of a doctor for their child. A third of rural mothers and a quarter of urban mothers expressed concern about lack of access. Shared parenting, a high socioeconomic status of mother and her partner and further training on leaving school, were associated with a greater satisfaction with existing services. Mothers with chronic psychiatric morbidity were more likely to express concern. Approximately one quarter of mothers expressed satisfaction with services overall. Specific improvements for child health services included reduced costs and waiting times together with an increase in the range of services available.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Persons with developmental disabilities living in the community have
a greater number and variety of health care needs than the average
population of the same age and sex. The erroneous assumption that
the generic health care system would be able to provide all necessary
services to the large number of individuals recently transferred from
state residential facilities to the community has proved to be an
unexpected disappointment to human service policymakers. In an
effort to remedy this situation, a program of health care services
was established by the New Jersey Department of Human Services at a
community teaching hospital to supplement the existing generic system
of medical care. Within four years, the program had rapidly grown to
provide care for 729 patients who had come to rely on the center for
primary care, specialty medical and dental services, and medical case
management. The demographic characteristics of this program are

described as well as data on morbidity, service utilization, and special problems encountered when care was provided to this complex and *medically* *underserved* population. Author-abstract.

TI Epilepsy in developing countries: a review of epidemiological,
sociocultural, and treatment aspects.
SO Epilepsia. 1988. 29 Suppl 1. P S36-54.
JT EPILEPSIA.
PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).
LG English (EN).
AB In this report, aspects of epilepsy that differ in developing and in
developed countries are reviewed. This is inevitably an incomplete
and impressionistic survey, because data on many aspects in
developing countries are scarce, and because it is difficult to
generalise meaningfully about the enormous diversity of countries and
populations that make up the developing world. Epidemiological
studies of prevalence and incidence are reviewed with an emphasis on

the problems inherent in work in this area in developing countries. Data concerning seizure type, aetiology, and severity of seizures in the Third World are contrasted with those from developed countries. Sociocultural aspects of epilepsy have been poorly studied, and yet are fundamental to effective medical management. The social effects of epilepsy and the local perceptions of cause and of treatment are discussed from work in Africa, Asia, and South America. The principles and success of treatment in the Third World may differ considerably in developing and developed countries. In the Third World, medical manpower is scarce, and epilepsy is managed essentially by primary care resources, without specialised investigations or personnel. The principles of drug therapy may not be understood by patients, and the supply of drugs is often erratic; and these are major reasons for poor compliance with treatment. World Health Organisation (WHO) initiatives have stressed the extensive use of paramedical personnel and of an essential drugs list, but this emphasis may be misdirected, and in practice neither proposal has achieved much success. The recommendation that phenobarbital be extensively used in the Third World, because of its cheapness and efficacy, is also of doubtful merit, as there are well-known and major drawbacks to the widespread use of this drug. Computations of treatment gap figures in three developing countries suggest that between 80-94% of patients with active epilepsy are not receiving anticonvulsant therapy, and cost is only one of a number of reasons for this. The key to improvements in medical treatment lie with a better understanding of the patients' cultural concepts of epilepsy and its treatment, improved drug supply and availability, and efforts to improve education amongst general practitioners and other primary care medical personnel. AB The authors recognize that social, economic and political factors
play a larger role in determining public health policy than do
epidemiological principles such as the analysis of needs, demand and
supply. Nevertheless, demographic and mortality statistics,
information from the 1983 registers of medical and dental
practitioners, and that of nurses, as well as information on hospital
beds were reviewed to describe health care requirements and resources
in South Africa. The maldistribution observed in health needs and
services closely parallel the divisions in South African society
imposed by the apartheid policy. It is concluded that fundamental
political change is required to reduce this maldistribution. The
provision of preventive and promotive health services for children in
African rural and peri-urban areas was identified as a health care
requirement of high priority. It is thought that the need in these
geographical regions might best be met by employing primary health
care workers at a lower level of training than doctors with an
accessible, supporting referral system. In addition, the quality of

health care data being collected needs to be improved. It is suggested that both these problems be approached on a regional basis, and preferably under a single health authority, rather than the current fragmented health service. Author-abstract.

JT JOURNAL OF MEDICAL EDUCATION.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB The Rural Physician Associate Program (RPAP) at the University of Minnesota Medical School is a clinical education experience for third-year students that lasts nine to 12 months. In 1970 the Minnesota legislature required the medical school faculty to find an educational method to redistribute physicians into the *medically* *underserved* rural areas of Minnesota or lose state funds for the medical school. After 16 years of the program, all 87 counties in Minnesota have an acceptable ratio of general physicians for the first time in the state's history. RPAP students work directly with and are supervised by general physicians practicing in rural areas; these preceptors have an average age of 40 years, are board-certified, and have 12 years of clinical experience. They give their teaching services and a \$2,500 stipend to the student; the state provides \$7,000 to the student with no obligation that the student practice in rural Minnesota after training. The preceptors, RPAP staff members, and visiting university faculty members provide 50, 30, and 20 percent, respectively, of a student's grades for the program; the student receives six months of credit for the program. As of 1986, 57 percent of the former RPAP students in practice were practicing in rural communities, with a majority in Minnesota and a majority in towns with populations less than 10,000.

 SO Public-Health-Rep. 1987 Nov-Dec. 102(6). P 686-91.
 JT PUBLIC HEALTH REPORTS.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB Federal funding programs have, since the 1960s, been available in a
 variety of forms to deal with problems of access to medical care for
 the *medically* *underserved.* Certain programs, such as the National
 Health Service Corps, have recently pulled back from their points of
 maximal impact in terms of numbers of obligated physicians in the
 field. This change leaves a need for greater contributions by State
 and local entities in the face of Federal retrenchment. The health
 service district (HSD) is one such mechanism for filling the gap. It
 has been available under this name in Arizona law since 1977, but the
 first such district in the State is only now under development in a
 small copper mining community. Similar to school districts in
 concept, the HSDs allow residents in their catchment areas to tax
 themselves for the purpose of delivering primary health care. Two
 successful HSDs--or similar entities--in other States are described.
 One program is in Stickney, IL, and other in Condon, OR. The
 political success and financial viability of the Condon program are
 documented. Author-abstract.

 LG English (EN).
 AB Selected urban and rural Alabama populations were compared by age, sex, and race on the prevalence of hypertension and uncontrolled hypertension and the percentage of treated hypertensives with controlled blood pressure. We found the following results: (1) Rural women had a significantly higher prevalence of hypertension than urban women. (2) The prevalence of uncontrolled hypertension was significantly higher for urban white men than for their rural counterparts. (3) The prevalence of uncontrolled hypertension was significantly higher for rural black women aged 30 to 39 than for the same age group of urban black women. (4) Rural dwellers generally had much better blood pressure control than urban, though this was not manifested evenly across groups. Statistically significant differences were found for white men and women of all ages combined and in three of four age groups. Reasons for the rural-urban differences are unclear, but the rural area surveyed was served by nurse practitioner clinics that strongly emphasized patient education. Author-abstract.

SO J-Med-Educ. 1987 Oct. 62(10). P 810-7.
JT JOURNAL OF MEDICAL EDUCATION.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB In an effort to make the geographic distribution of physicians closer
to the distribution of the population as a whole, in 1971 the states
of Washington, Alaska, Montana, and Idaho established the WAMI
Program. In a departure from the Flexnerian model of medical
education, the WAMI Program was organized to distribute the
components of medical education throughout the region, both at the
medical center at the University of Washington School of Medicine and
at remote sites. In the present article, the authors describe the
results of the first seven years of the program (1975-1981) in terms
of the geographic and specialty distribution of the school's
graduates before and after the establishment of the program. At the
time of the study, 23 percent of the graduates with WAMI Program
experience practiced in nonmetropolitan areas as defined by the U.S.
Bureau of the Census. Only 13 percent of all U.S. physicians
practiced in such areas in 1981, while 24 percent of the U.S.
population lived there. In addition, 61 percent of the graduates
with program experience were in primary care practice in contrast to
35 percent of all U.S. physicians. If all U.S. physicians behaved
as these graduates do, the distribution of U.S. physicians would be
reversed, with the proportion of physicians practicing primary care
in nonmetropolitan areas being larger than the proportion of the
population living in those areas. Author-abstract.

TI Incantations in the dark: Medicaid, *managed* *care,* and maternity *care.*

SO Milbank-Q. 1988. 66(4). P 661-93.

JT MILBANK QUARTERLY.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Public program reforms in the 1980s have substantially increased the numbers of poor pregnant women potentially eligible for Medicaid coverage. Structural deficiencies in the Medicaid program, together with inadequate arrangements in *managed-care* plans, however, have not led to generally acceptable levels of maternity *care.* Demonstration projects indicate that Medicaid can be modified cost effectively to underwrite early, continuous, and comprehensive *care* delivery. Recommendations are suggested for eligibility guarantees, enrollment safeguards, benefit and treatment protocols, provider recruitment, quality control, and sufficient payment rates to overcome barriers to adequate levels of material health *care.* Author-abstract.

AB In a client-centered case management model, the case manager's
personal relationships with the client and caregiver help the case
manager to effectively assess the client's needs, coordinate needed
care, and monitor services provided. At Connecticut Community *Care,*
Inc (CCCI), case management is a six-step process that includes
referral, assessment, *care* planning, service coordination,
monitoring, and documentation. The program is particularly notable
for its use of a structured, comprehensive assessment tool and a case
management team consisting of a nurse and a social service
professional. Author-abstract.

 AB The driving concern of policy thinking in regard to both the elderly and AIDS patients has been cost containment. It has been presumed that the best way to cut costs, as well as to serve the medical and emotional needs of AIDS patients, is to limit hospital and nursing home stays and expand the role of community-based services. The experience of the elderly has demonstrated, however, that these services have had little impact on the use of institutional *care,* only limited outcome benefits, and have not reduced the overall costs; rather, they have increased the utilization of all services and total expenditures. In the case of AIDS patients, a preoccupation with community *care* alternatives to hospitalization fails to acknowledge the central role of medical *care* in the management of the disease. JT INQUIRY.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Mandatory *managed-care* programs for Medicaid beneficiaries typically require enrollees to select the provider who will act as gatekeeper to the medical *care* system. A substantial number of beneficiaries, however, do not exercise this choice and are assigned a gatekeeper. Using consumer survey data from the Missouri *Managed* Health *Care* Project, we examined characteristics and use experiences of assignees compared with selectors. We found that the assignees enjoyed better health than the selectors and were less likely to have had a regular source of *care* prior to the program. The utilization experience was similar for both groups. We conclude that the basis for not making a choice is one of indifference. Author-abstract.

TI Nursing case management. Resolving the DRG paradox.
SO Nurs-Clin-North-Am. 1988 Sep. 23(3). P 503-20.
JT NURSING CLINICS OF NORTH AMERICA.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Nursing Case Management as described here was developed in an ideal conditions: a full census, a 30 per cent increase in patient volume over five years, a nursing shortage, no grants or outside funding, no clinical specialists or clinical ladder, and no computerized documentation system. No more staff or salary was added as we focused our attention on the new tools, roles, and structures necessary to achieve cost and quality outcomes. However, nursing case management has worked because of some very key elements: 1. A firm commitment to the belief that staff nurses must be accountable for the outcomes of the *care* that they have planned, given, *managed,* and continuously evaluated. 2. A combination of top-down organizational development strategies with excellent staff nurse involvement at each juncture. 3. Negotiation and collaboration with physicians and hospital administration at key turning points. This includes the relentless articulation of patient-centered *care.* 4. A willingness to learn and risk together as a whole department--across levels, across specialties. This includes a constant balance of moving from concrete examples and problems to reconceptualizing the issues. 5. Listening, responsiveness, humor, and acknowledging contributions of everyone. More than any other

principal, the case manager must be a central caregiver to a patient to ensure cost/quality outcomes. Otherwise case management only adds to the cost of health *care* by adding another level of bureaucracy. Nurses have always *managed* the *care* of patients, but to stay effective and committed, they need to take increased authority in their patients' entire episode of *care* and develop formal collaborative practice groups. In other words: "Prospective payment has changed the health *care* product from a day of *care* (or a visit) to an entire case or episode of illness. More than just a new way of paying for *care,* it has changed our way of planning, managing, and thinking about health *care.*" Looking at the future entails understanding our business, and then changing our practice patterns for the change in the times. Necessity will foster invention; Nursing Case Management provides a model and technology for innovation. Author-abstract.

AB The traditional, *stepped-care* approach to the treatment of hypertension has been challenged by the introduction of new and more expensive medications. Because hypertensive patients include those who can least afford high-priced medication, such prescribing patterns may result in noncompliance and, further, may cause patients to switch to physicians or *managed-care* systems more considerate of their economic needs. Physicians should therefore consider cost-effectiveness in treatment of hypertensive patients.

JT MEDICAL *CARE.*
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB The prescription refill records of centralized pharmacies are a

potential source of information about patient compliance with long-term medications. We developed a method for assessing compliance in such settings and validated our measures using pharmacy data and clinical information from patients with seizure disorders and hypertension. For patients taking the anticonvulsant medication phenytoin, compliance with the drug correlated significantly with mean plasma phenytoin level. For patients on antihypertensive medications, compliance with the treatment regimen correlated with control of diastolic blood pressure. Many patients (15% in the phenytoin validation, and 33% in the blood pressure validation) obtained substantial oversupplies of medications; for these patients, the direct relationship between compliance and drug effect was not evident. A majority of seizure patients with "subtherapeutic" mean plasma phenytoin levels were identified as noncompliant using our measures. We conclude that our method of assessing compliance in obtaining medications is feasible in *"managed care"* settings, appears to be a valid correlate of drug effects, and may be useful in research and patient *care.* Author-abstract.

TI Identifying catastrophic psychiatric cases. Targeting *managed-care* strategies.

SO *Med-Care.* 1988 Aug. 26(8). P 790-9.

JT MEDICAL *CARE.*

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Case management programs, a specialized form of utilization review (UR), focus their interventions on catastrophic cases, which comprise the minority of patients while accounting for the majority of costs. Many case management programs base their case identification and review criteria on diagnosis alone, although research has shown that it is a poor predictor of length of stay. Using claims data from a large nationwide insurer, the authors developed an empirical approach

to identifying potentially catastrophic cases. The findings suggest that, in addition to diagnosis, other factors such as age and treatment setting contribute to long stays and high costs and thus should be used to identify catastrophic cases for case management interventions. Strategies to target case management programs must be considered not only in light of their impact on cost but on the quality of *care* for individual patients. Author-abstract.

 care?

SO JAMA. 1988 Jun 3. 259(21). P 3145-9.
 JT JAMA.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB In what proportion of a patient's total health *care* is the primary physician involved? By means of calendar diaries and telephone interviews, 211 primary *care* patients from community practices of the Dartmouth Primary *Care* Cooperative Information Project were followed prospectively for one year. We found that a substantial proportion of *care* was *managed* (that is, either actually provided or coordinated in advance) by the patient's primary physician. Specifically, criteria for a primary physician's role in management were met by 75% of 1379 ambulatory visits to physicians, 33% of 786 visits to nonphysician health *care* providers, 81% of 26 nonemergency hospitalizations, and 78% of 2769 prescriptions. Primary physicians in these settings appear to function as case managers even when they are not participating in formal *managed-care* systems.

TI Can neurologists survive or thrive with health *care* reform?
`editorial:.
SO Ann-Neurol. 1993 May. 33(5). P 441-4.
JT ANNALS OF NEUROLOGY.
PT EDITORIAL (EDI).
LG English (EN).
AB The economics of present-day health *care* and the politics of recent
elections will forever change the practice of neurology. *Managed*
care, outcomes research, limits on price and volume of services,
diagnostic and treatment restraint, divestiture of ownership in
health facilities, malpractice reform, increased use of preventive
services, and administrative simplifications will all be part of the
new practice of medicine, and hence neurology. The challenge for
neurologists will be to define cost-effective neurological services,
put greater emphasis on the most prevalent and costly diseases of the
nervous system, and convince primary *care* providers and patients of
their value. Health *care* reform is an opportunity and challenge for
neurologists to improve patient access while achieving acceptable
financing mechanisms. Author-abstract.

 TI Pneumonia mortality reduction and quality improvement in a community hospital.
 SO QRB-Qual-Rev-Bull. 1993 Apr. 19(4). P 124-30.

JT QRB. QUALITY REVIEW BULLETIN.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Rather than explain adverse results on the basis of flawed data, a physician-directed quality improvement program was initiated to improve the delivery of *care* to patients admitted to Forbes Health System (Monroeville, Penn) with community-acquired pneumonia. Following the introduction of standardized physician orders and modification and elimination of inefficient processes of *care,* the mortality rate for this infection decreased from 10.2% to 6.8%. This initial exposure to the quality improvement process led to the participation of the medical staff in other related clinical and support service initiatives. In addition, Forbes and its clinical partners are now better positioned to respond to increasing government, *managed* *care,* and consumer inquiries relating to cost and quality outcomes. Finally, this positive experience facilitated the organization's transition from inspection-based quality assessment to quality improvement activities, which should assist in efforts to meet or exceed new accreditation standards. Author-abstract.

JT JOURNAL OF CASE MANAGEMENT.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Ethnic identity has been commonly stereotyped in the gerontological literature as a disability for the elderly, placing them in so-called double jeopardy. However, new knowledge and changing attitudes in American society have resulted in a far more positive attitude toward the role of cultural pluralism. Ethnographic field research strongly suggests that ethnic affiliation can proffer the elderly a spectrum of psychological, social, and cultural resources not generally available to them in the larger society. For case managers with largely ethnic client populations, understanding the dynamics of ethnicity can enhance their ability to meet client needs successfully with resources from both within and outside the client's culture.

 LG English (EN).
 AB This article reviews some critical elements of case management as they apply to Puerto Ricans seeking quality and consistency in health *care* and social services in a system which is culturally foreign, difficult to negotiate, and frequently unresponsive, especially to those with limited economic resources and government rather than private insurance. Following a brief outline of some principles of case management, we discuss aspects of Puerto Rican history, family organization, and health-seeking behavior that relate to case management. Descriptions of three programs illustrate several case management approaches that combine methods to access *care* with those needed to organize coordinated inter-institutional *care.* Finally, we suggest ways for case managers to successfully work with Puerto Rican families.  TI National health policy: back to the future. Ad Hoc Committee on
 National Health Policy American Speech-Language-Hearing Association.
 SO ASHA-Suppl. 1993 Mar. 35(3 Suppl 10). P 2-10.
 JT ASHA. SUPPLEMENT.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB After an extensive review of the literature and discussion of both
 national and state proposed health plans, the committee arrived at
 the following conclusions: 1. The issues that prompted development
 of the 1971 American Speech-Language-Hearing Association's (ASHA)
 Position Statement on National Health *Care* have not been resolved or
 altered. 2. Few significant national health plans or policies are
 being supported by the Bush Administration other than *managed-care*
 plans. 3. A national health policy will be driven by the
 development of state health policies and plans. 4. Implementation
 of national or state health plans will affect both professions at all
 service provision sites, including public schools. 5. Five general
 models apply to all existing or proposed national and state health
 policies or plans: single payer (e.g., a Canadian-style plan) minimum
 basic benefits ("play or pay") expanded Medicare or Medicaid benefits
 rationed healthcare (e.g., Oregon plan) *managed* *care* (e.g., health
 maintenance organizations) 6. There will be continued efforts to
 eliminate Medicaid mandates. 7. ASHA needs to advocate for the
 inclusion of rehabilitative services as basic rather than optional
 services in all health plans. 8. ASHA must advocate for adequate
 access to quality *care* regardless of healthcare or education provider
 setting. Author-abstract.

LG English (EN).
AB Ear infections, commonly referred to as otitis media, are one of the most commonly occurring problems of childhood. The "hit and miss" treatment of this disorder can result in parental frustration and early referral for surgical treatment. The application of *managed* *care* principles require that a standard approach to *care* be employed for the treatment of this condition. It should be high-quality, low-cost, and accessible to the patient population. The use of group appointments for common medical problems was first recommended by the military-commissioned PRISM III report of the early 1980s. It was felt that this technique could increase access and improve quality of *care.* A modification of this concept was tested that allowed the advantages of group parent teaching and medical history intake while

preserving the individualized approach to *care* for a larger number of patients. This method was found to increase the productivity of the clinic by over 100%, while reducing the referral of patients outside the AF clinic to less than 1%. Author-abstract.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB OBJECTIVE--To develop and test a method for comparing the
appropriateness of hysterectomy use in different health plans.
DESIGN--Retrospective cohort study. SETTING--Seven *managed* *care*
organizations. PATIENTS--Random sample of all nonemergency,
non-oncological hysterectomies performed in the seven *managed* *care*
organizations over a 1-year period. Patients who were not
continuously enrolled in a plan for 2 years prior to their
hysterectomy were excluded. MAIN OUTCOME MEASURES--Proportion of
women undergoing hysterectomy in each plan for inappropriate clinical
reasons according to ratings derived from a panel of *managed* *care*
physicians. RESULTS--Overall, about 16% of women underwent
hysterectomy for reasons judged to be clinically inappropriate. Only
one plan had significantly more hysterectomies rated inappropriate
compared with the group mean (27%, unadjusted). Adjusting for age
and race did not affect the rankings of the plans and had little
effect on the numeric results. CONCLUSION--The rates of
inappropriate use of hysterectomies are similar to those for other
procedures and vary to a small degree among health plans. This
information may be useful to purchasers when they consider which
health plans to offer their employees. Author-abstract.

JT JOURNAL OF THE NATIONAL MEDICAL ASSOCIATION.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB In the search for fairness of access to health *care,* value for the
money spent, and high quality of patient *care,* the United States has
vacillated between advocacy of government regulations (the 1970s) and
of market-driven, pro-competitive (1980s) approaches. The possible
enactment of President Clinton's health reform plan with a
managed-care strategy (1990s) calls for paying physicians and other
providers in a manner that often induces them to minimize the
provision of services to patients per episode of illness. This
article discusses the impact of such legislation on patients,
physicians, and other providers. It then argues that the President's
managed competition approach, which micromanages *health-care*
services, will fail except by concurrently implementing his proposed
National Health Board's global budgetary concept. The major reason
is that health reform for the 36.6 million uninsured Americans, who
are mostly the working poor and their dependents, is only practical
and affordable if stringent policies are adopted that reorganize
available *health-care* resources and simultaneously implement
cost-containment constraints. Author-abstract.

 AB A new approach to universal health insurance combining *managed*
 competition and global budgets promises to break the impasse blocking
 comprehensive health reform. The central innovation is the
 development of regional health insurance purchasing cooperatives
 (HIPCs) as managers and reorganizers of the market and platforms for
 global budgets. Financing would be based on community-rated
 premiums, with obligations to employers capped as a percentage of
 payroll and to individuals as a percentage of family income. Budgets
 would cap the mandated core of spending and set a target for
 out-of-pocket expenditures. Author-abstract.

 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB Illustrative estimates suggest that if all acute health *care* services were delivered through staff- or group-model health maintenance organizations (HMOs), national health spending might be almost 10 percent lower. If the delivery of all such services (except those now provided by staff- or group-model HMOs) were subject to utilization review arrangements incorporating precertification and concurrent review of inpatient *care,* spending might be 1 percent lower. The estimates assume no changes in the health *care* system apart from expansion of these two forms of *managed* *care* to cover all

insured persons. They also assume that moving to universal *managed*
care would produce a one-time drop in the level of national health
spending with no subsequent effect on spending growth.

JT HEALTH AFFAIRS.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB *Managed* competition in health *care* is an idea that has evolved over
two decades of research and refinement. It is defined as a
purchasing strategy to obtain maximum value for consumers and
employers, using rules for competition derived from microeconomic
principles. A sponsor (either an employer, a governmental entity, or
a purchasing cooperative), acting on behalf of a large group of
subscribers, structures and adjusts the market to overcome attempts
by insurers to avoid price competition. The sponsor establishes
rules of equity, selects participating plans, manages the enrollment
process, creates price-elastic demand, and manages risk selection.

Managed competition is based on comprehensive *care* organizations that integrate financing and delivery. Prospects for its success are based on the success and potential of a number of high-quality, cost-effective, organized systems of *care* already in existence, especially prepaid group practices. As it is outlined here, *managed* competition as a means to reform the U.S. health *care* system is compatible with Americans' preferences for pluralism, individual choice and responsibility, and universal coverage. Author-abstract.

AB This DataWatch estimates the public cost of providing universal coverage under a *managed* competition model. First, a uniform benefit package is specified; next, the lowest-cost premium for this coverage is estimated, based on average costs in a *well-managed* health maintenance organization (HMO). Based on these estimates, the cost of premium subsidies and tax revenue effects are determined. It is estimated that if coverage is extended to currently uninsured persons using these estimates and assumptions, spending for these persons will increase 73.9 percent over current levels. The authors estimate a net increase of \$47.9 billion in 1993 health spending under a *managed* competition program with low patient cost sharing. This includes savings of \$4.5 billion from wider use of *managed* *care* and \$11.2 billion in administrative cost savings. Author-abstract.

AB The essays in this volume concentrate heavily on *"managed*

competition," which is merely a particular form of controlling the flow of funds from an insurance pool to the providers of health *care.* By contrast, this essay emphasizes the funneling of money into the insurance fund. It is argued inter alia that American business has been a quite unreliable partner in the financing of American health *care* and also a major cost driver. A reformed health system should reduce the role of business to the mere collection of premiums at the nexus of payroll. Author-abstract.

AB Because *managed* *care* is likely to feature prominently in a reformed
health *care* system, policymakers need to examine the impact *managed*
care will have on medical practice, physician supply, and access to
primary *care* providers. Goals for work-force reform should focus on
five areas: (1) training physicians in the generalist disciplines of
family practice, general internal medicine, and general pediatrics;
(2) shaping the physician work force to reflect the nation's ethnic
diversity; (3) distributing physicians in a geographically equitable
way; (4) maintaining the current physician-to-population ratio rather
than letting it continue to grow; and (5) establishing supply needs
for nurse practitioners, primary *care* physician assistants, and
certified nurse midwives. Author-abstract.

JT DERMATOLOGIC CLINICS.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Protein issues confront the dermatologic practitioner in this last decade of the twentieth century, including 1) the role of *managed* *care;* 2) the decline of direct access to the specialist; 3) malpractice liability and the need for reform; 4) declining reimbursements in the face of escalating practice overhead; and 5) conflict between the individual's right to *care* and society's ability to subsidize that right. Correcting and improving the American health *care* system demands a return to the emphasis and values that made that system the envy of the entire world. We must re-emphasize the sanctity of the doctor-patient relationship, halt the incursion upon physician autonomy, and eliminate those third party factors such as insurance companies, bureaucrats, and administrators that accentuate commerce instead of compassion in medicine. It is hoped that by expanding and equalizing the American health *care* system, it is not made unpalatable and unresponsive to every citizen.

JT AMERICAN JOURNAL OF CLINICAL PATHOLOGY.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Largely because of increased *health-care* costs, a variety of *managed-care* programs have been developed, and payment plans based on capitation will probably predominate in the future. Capitated, per-case, or per diem payment plans alter the traditional independence of *health-care* providers from the payment system. In these systems, clinical laboratory use becomes a resource to be *managed,* rather than a neutral third party or a source of income. Under capitated payment systems, clinicians will be motivated to reevaluate their own clinical laboratory resource use. Successful laboratory medicine specialists will understand these trends as well as the impact of newer payment plans on the relationship between themselves and clinicians, and develop new strategies to work with clinical colleagues to effect change. Author-abstract.

PT HISTORICAL-ARTICLE (HRT). JOURNAL-ARTICLE (ART).
LG English (EN).
AB This article provides a short historical review of the HMO movement to set the stage for current HMO developments. It notes the underlying causes of the proliferation of HMO *managed* *care* models. It defines what should be the rudiments of a quality HMO program and how the changing societal environment will bring new pressures to bear on HMO programs of the future. As related to the future, the author outlines a direction for national health *care* reforms. The article concludes that the health *care* emphasis of the 90s should be in returning some of the responsibility of health *care* to individual Americans through *self-care* programs that focus on behavioral change, in turn, leading to healthier Americans, the keys to containing out of control health *care* costs. PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).
LG English (EN).

AB The phenomenon of *managed* *care* is misperceived by its critics as a movement. Atheoretical in nature, and driven by spiralling health *care* costs, it represents the introduction of an executive function into the free-for-all (a supremely ironic term) of American medicine. Part one of this article traces the origin and development of the mental health carve-out, relating it to its antecedents, and describing its 3 overlapping phases: utilization review, discounted fees, and network development and management. Part two describes the key concept of the continuum of *care* and the role of the case manager in monitoring a *care* episode. The article concludes by anticipating seven future trends and calling for mental health leadership to recognize and ally with the need to manage resources in a more rational and efficient manner. Author-abstract. 41 Refs.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB HMO staff model mental health programs have particular expertise in providing these services in an integrated fashion within the context of a total medical *care* system. "Carve-out" approaches to *managed* mental health *care* risk losing the added value found in primary *care* based integrated mental health services. Employers as purchasers of *care* are seeking demonstrated value in services, and the rise of specialty mental health *managed* *care* firms is bringing the efficiencies of *managed* mental health *care* familiar to HMO's to a broader audience. Faced with employer concerns, and this new competitive environment, many HMO's are examining their mental health

services to determine how these services may respond to the needs being expressed by employers today for new program options. The Community Health Plan's (CHP) experience is presented to illustrate one approach HMO's are taking in today's competitive health *care* environment. Author-abstract.

JT JOURNAL OF EMERGENCY NURSING.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB The actual development of the CP is an easy undertaking that an experienced emergency nurse can accomplish. The important points to remember are as follows: (1) include all disciplines that provide patient *care* in the development of the CP, (2) use realistic time frames (i.e., those currently found to be true in the emergency department, not those that are perceived to be ideal), (3) thoroughly educate the staff about the value of the CP in the emergency department, and, finally, (4) make sure that staff members know how to document variances. CPs in the emergency department give physicians and nurses common ground on which to negotiate patient *care* management more efficiently and effectively. They are a logical way to bring case management into the acute *care* setting. With the cost of ED visits continually rising, patient acuity levels increasing, and resources declining, expedient, coordinated, multidisciplinary action is crucial in giving total quality *care* to each patient. Author-abstract.

 AB Railway surgery was an organized movement in the late 19th century
 that had as its primary goal the systematic study of accident or
 trauma surgery. Railway surgeons, although often regarded with
 contempt by their fellow physicians, fostered such revolutionary
 concepts in health *care* provision as private inpatient hospitals and
 rudimentary *managed* *care* plans. Railway surgery and its proponents
 are a long-forgotten chapter in the history of US surgery, but they
 serve as an apt example of how studying and understanding the past
 can enable us to be better prepared to cope with the present and the
 future. Author-abstract.

TI The trade-offs of developing a case management model for chronically mentally ill people.

SO Health-Soc-Work. 1993 Feb. 18(1). P 20-31.

JT HEALTH AND SOCIAL WORK.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).

LG English (EN).

AB This article addresses the role of case management in the *care* of chronically mentally ill people. Trade-offs often occur because case management is frequently used to achieve the conflicting goals of reducing service use costs and raising the quality of life for clients. Despite these trade-offs, case management can be effective if it is designed so that services match client needs and the costs of services are measured accurately. Case management for chronically mentally ill people is particularly difficult to design because their level of functioning and need for intensive services are such that the cost to deliver the appropriate services is great. The profit-maximizing nature of the U.S. health *care* system makes some form of capitation likely in the design of case management services for this population. Author-abstract. 68 Refs.

TI Healthcare reform: the role of coordinated critical *care.*
SO *Crit-Care-Med.* 1993 Mar. 21(3). P 457-64.
JT CRITICAL *CARE* MEDICINE.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB OBJECTIVE: To evaluate and editorialize the evolving role of the discipline of critical *care* as a healthcare delivery system in the process of healthcare reform. DATA SOURCES: The sources included material from the Federal Office of Management and Budget, Health *Care* Financing Review, President Bush's Office, Association of American Medical Colleges, and publications of the Society of Critical *Care* Medicine. STUDY SELECTION: Data were selected that the author felt was relevant to the healthcare reform process and its implications for the discipline of critical *care.* DATA EXTRACTION: The data were extracted by the author to illustrate the forces behind healthcare reform, the implications for the practice of critical *care,* and role of critical *care* as a coordinated *(managed)* *care* system in the process of healthcare reform. DATA SYNTHESIS: Healthcare reform has been initiated because of a number of considerations that arise in evaluating the current healthcare delivery system: access, financing, cost, dissatisfactions with the mechanisms of delivery, and political issues. The reform process will occur with or without the involvement of critical *care* practitioners. Reforms may greatly alter the delivery of critical *care* services, education, training, and research in critical *care.* Critical *care* has evolved into a healthcare delivery system that provides services to patients who need and request them and provides these services in a coordinated *(managed)* *care* model. CONCLUSIONS: Critical *care* practitioners must become involved in the healthcare reform process, and critical *care* services that are effective must be preserved, as must the education, training, and research programs. Critical *care* as a healthcare delivery system utilizing a coordinated *(managed)* *care* model has the potential to provide services to all patients who need them and to deliver them in a manner that is cost effective and recognized as providing added value. Author-abstract.

TI Factors related to successful goal attainment in case management.

SO J-Case-Manag. 1992 Winter. 1(4). P 117-23.

JT JOURNAL OF CASE MANAGEMENT.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Goal planning is fundamental to the case management process. Manager

and client identify specific long-term goals and then systematically break them down into the incremental behaviors needed to be accomplished to achieve each goal. The goal-setting process may fail as a result of four types of factors: (1) behavioral, (2) cognitive, (3) affective, and (4) environmental. To decrease the likelihood of failure, case managers must be knowledgeable about goal planning. They must help the client set goals that are expressed positively, that are client focused, realistic and achievable, measurable, and easily understood, with one observable outcome per goal. For both case manager and client, setting and attaining goals must be viewed as part of a continuing learning process, rather than a success-failure dichotomy. Author-abstract.

AB Clinics Without Walls will function as integrated medical practice
business organizations for the purpose of carrying out ventures
approved by their boards of directors, including the delivery of
patient *care* services under contract to *managed* *care* organizations or
others. The networks will be responsible for receiving revenue for
contracted services and for paying expenses. Patient *care* should be
enhanced by this structure, which will result in improved
communications and information exchange among participating
physicians and greater patient access to convenient, decentralized
medical facilities. Patients and physicians will likely benefit from
the expanded services made available through shared network
resources. As mentioned above, the MMA and the Hennepin and Ramsey
county medical societies are currently developing a detailed Clinics
Without Walls prototype that will be made available for
implementation during the first half of 1993. Author-abstract.

TI The effect of insurance benefit changes on use of child and
adolescent outpatient mental health services.

SO *Med-Care.* 1993 Feb. 31(2). P 96-110.
 JT MEDICAL *CARE.*
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB Use of outpatient mental health services by dependent children younger than 18 years of age enrolled in the Blue Cross and Blue Shield Federal Employees Plan (FEP) is examined in 1978 and 1983 focusing on a cut in benefits and a shift from high- to low-option plan enrollment between those years. While use rates increased from 2.13% to 2.76% by 1983, the average number of visits decreased from 18.9 to 12.8. High-option plan use exceeded low-option plan use in both years--2.26% versus 0.81% in 1978 and 3.58% versus 1.93% in 1983. In addition to benefit plan, ethnicity, parent's education, type of provider, and type of treatment setting also significantly predicted amount of use. Despite the strong evidence of the effects of benefit coverage, it is likely that need exceeded use even in this insured population of children and adolescents. Implications of the findings are discussed in the context of recent dramatic changes in mental service delivery including privatization, *managed* *care* initiatives to cut costs, and growing pressures for national health insurance. TI Changes in health and job attitudes of case managers providing intensive services.

SO Hosp-Community-Psychiatry. 1993 Feb. 44(2). P 168-73.

JT HOSPITAL AND COMMUNITY PSYCHIATRY.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB OBJECTIVE: The health, personal life, and attitudes of case managers providing intensive services to severely mentally ill clients were evaluated to see how the managers changed over their first 18 months on the job. The authors report here on changes on major variables related to health status and job attitudes. METHODS: A cohort of 82 case managers newly hired during the first year of New York State's intensive case management program was followed for 18 months. A battery of measures of health, life events, life satisfaction, social support, job situation, and job attitude was administered by mail questionnaire at job entry and at three, 12, and 18 months to case managers who remained employed in the program. RESULTS: Approximately 80 percent of the eligible (still-employed) case managers responded at each time point; 64 were still employed at the end of the study. Over time they experienced increasing amounts of job stress and emotional exhaustion, depersonalized clients more, and reported significantly more stress-related physical symptoms and depressive symptoms. However, their sense of personal accomplishment and their job satisfaction remained stable. CONCLUSIONS: Case

managers appeared able to overcome job pressures and persevere in their professional commitment. What difficulties they had appeared to level off after one year, at least among those who continued in their positions. Although the findings do not indicate that case managers need intensive help, early support and preventive intervention for job difficulties would be helpful.

AB Policy-makers are concerned to find ways to improve the quality,
accessibility and continuity of *care,* contain costs and ultimately to
reduce the rate of institutionalisation. The health reform in New
Zealand proposes to open up the way for nurses to be more extensively
and effectively involved in primary and community based *care* in order
to meet these needs. The role of nurses as community based nurse
case managers in the United States is reviewed and demonstrates very
clearly not only is the quality of health *care* enhanced but also the
client and fiscal outcomes improved. The challenge from the reform
is for nurses to see the opportunities and to take the initiative
before it is taken by other disciplines. Author-abstract.

LG English (EN).
AB Evaluation of physician competence has traditionally been defined by the medical profession largely through standardized tests and board certifying examinations. However, a level of physician evaluation that takes place outside academic medical centers and certifying boards is rapidly developing. This article describes three programs for such physician evaluation: (1) the program of US Healthcare, a national *managed* health *care* company; (2) the DEMPAQ--Developing and Evaluating Methods to Promote Ambulatory *Care* Quality--project, a joint research effort between Harvard University (Cambridge, Massachusetts) and the State of Maryland's (and District of Columbia's) Peer Review Organization (PRO); and (3) a project initiated by the American College of Physicians (ACP) in Philadelphia, Pennsylvania, to assess both medical competence and technical performance in the hospital setting. The authors argue for the need to inform physicians-in-training about the types of evaluation to which they will be subjected over the courses of their careers. In order to further this goal, the authors advocate increased collaboration between leaders in the academic setting and those spearheading these new programs for assessment of physician performance. Author-abstract.

AB 1. It is important to examine client and staff satisfaction with the RN case management (RNCM) model to enhance the quality of *care* in psychiatric settings. 2. Ninety-two percent of clients surveyed ranked the RNCM *care* as "excellent" or "above average." Clients valued most the humanistic role of the RNCM and repeatedly commented on the importance of the nurse being caring, genuine, and supportive. 3. RNCMs expressed high satisfaction with their role, which they described as collaborative with the psychiatrist, yet also professional and independent. Psychiatrists expressed a high degree of confidence that clients were receiving excellent *care* by competent nurse professionals. Author-abstract.

 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB OBJECTIVE: To quantitatively identify predictors and determinants of length of psychiatric hospital stay for children. METHOD: Forty-seven demographic, psychosocial stressor, psychopathology, and disposition variables were statistically reviewed as correlates of length of stay in 100 consecutive discharges from a child psychiatry inpatient service (age range 4-12) in a private hospital. Those with strong statistical significance were then analyzed by multiple regression. RESULTS: Greater severity of psychopathology (measured by the Children's Global Assessment Scale), greater severity of psychosocial stressors (by Axis IV scale), diagnosis of post-traumatic stress disorder, special educational and out-of-home dispositions, and severe tantrums in hospital all strongly predicted longer hospital stay. Diagnosis of adjustment disorder predicted shorter stay. Together these variables explained 57% of the total variance in length of stay. CONCLUSIONS: The most powerful of these predictor variables could potentially be measured at the time of admission, thus permitting accurate prediction of length of stay. A set of models was generated for this purpose. Author-abstract.

AB *Managed* *care* organizations have become significantly involved in
health *care* in the Denver metropolitan area. Their presence has
challenged psychiatric hospitals to reduce costs and length of stay.
In 1990, a locked private psychiatric unit was reorganized into
locked, open, and partial *care* services through which patients
progress at individualized rates. One treatment team manages
patients in all settings, allowing a reduction in staffing costs and
flexibility in treatment design. The hospital administration takes
an active role in facilitating collaborative decision making between
hospital clinicians and *managed* *care* representatives. In the first
year after reorganization, length of stay was significantly reduced;
90 percent of patients were discharged from 24-hour *care* within ten
days or less, whereas only 40 percent were discharged within that
time in the original program. Staffing costs were reduced by 15
percent. No increase in recidivism was noted. Author-abstract.

AB A fixed-prepayment system (case-based reimbursement) for patients initially requiring hospital-level *care* was evaluated for one year through an arrangement between a private nonprofit psychiatric hospital and a self-insured company desiring to provide psychiatric services to its employees. This clinical and financial experiment offered a means of containing costs while monitoring quality of *care.* A two-group, case-control study was undertaken of treatment outcomes at discharge, patient satisfaction with hospital *care,* and service use and costs during the program's first year. Compared with costs for patients in the control group, costs for those in the program were lower per patient and per admission; cumulative costs for patients requiring rehospitalization were also lower. However, costs for outpatient services for patients in the program were not calculated. Treatment outcomes and patients' satisfaction with hospital *care* were comparable for the two groups. Author-abstract.

 JT HOSPITAL AND COMMUNITY PSYCHIATRY.
 PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).
 LG English (EN).
 AB In the second part of a two-part paper, the three major proposals for U.S. health *care* reform--the government-sponsored model, the employment-based model, and the market reform model--are reviewed. Barriers to their success include the current economic crisis, the lack of a clear consensus, and the high costs of the proposals. Most proposals limit the extent of psychiatric coverage; some exclude such coverage from minimum benefit packages, an area of concern for clinicians. The author concludes that any substantial health *care* reform is unlikely in the near future. A thoughtful, realistic, and yet vigorous strategic plan is needed now to forestall the possible exclusion of significant mental health coverage. The basic elements of such a plan are reviewed.  AB Changes in health *care* on the national level are affecting perioperative nursing drastically. Perioperative nursing needs innovative approaches to guide the delivery of nursing *care* for patients whose operative procedures are performed outside traditional institutions. *Managed* *care* and case management are gaining in importance as more surgical procedures are performed in the

outpatient arena. New minimally invasive techniques call for new models of delivering professional nursing *care.* Any model that is developed must ensure that professional perioperative nursing is rewarded, quality patient *care* provided, and surgical procedure expenses reimbursed. Author-abstract.

JT JOURNAL OF PEDIATRIC HEALTH *CARE.*
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB The evolution of the role of the pediatric nurse practitioner in oncology specializing in the *care* of childhood cancer survivors is described, with certain aspects of the role solidified or expanded and new functions added. The early concept of the role included three interdependent functions: (a) clinician/caregiver, (b) educator, and (c) researcher. The functions of specialty *care* provider and educator remain strong; the role of researcher has been

expanded, and new role components, clinical/program manager and consultant, have been added. The central focus for the pediatric nurse practitioner in oncology is the survivor and family, which is extended to the clinic population and related groups by the blending of the pediatric nurse practitioner and clinical nurse specialist roles. Any role function on behalf of this clinical population should be assumed as necessary to provide comprehensive *care.*

 AB There is concern that children with chronic conditions are less
 likely to be enrolled in *managed* *care* systems and that they may not
 receive optimal *care.* We studied the relationship between enrollment
 in an Independent Practice Association (IPA) plan and utilization of
 ambulatory services among children in a suburban pediatric practice
 with one mild chronic condition--those receiving hyposensitization
 therapy for allergic diseases. Ambulatory utilization by IPA
 patients (N = 102) was determined by medical chart review for one
 year before and one year after each patient switched from Blue Cross
 to IPA coverage. Blue Cross hyposensitization patients (N = 57)
 matched for age served as controls. Patients receiving
 hyposensitization were more likely to have enrolled in an IPA than
 those not receiving hyposensitization (70% vs 45%, $p < .001$). Before
 enrollment pre-IPA patients had 41% fewer well-child *care* (WCC)
 visits than Blue Cross patients ($p < .01$); both underutilized WCC
 visits according to established guidelines. Controlling for age and
 baseline utilization, we found a significant increase in WCC and
 acute *care* visits after IPA enrollment ($p < .05$), but no change in
 hyposensitization visits or referrals. In this setting, there was no
 evidence for reduced access to ambulatory services but rather
 evidence for improved utilization of primary *care.* Author-abstract.

 AB *Managed* *care* organizations will be able to promote quality *care* as well as control costs by utilizing quality management approaches and practice guidelines. By so doing, organized systems of *care* could promote adherence to standards of quality and appropriateness. Focusing on systems of *care* is a major component of the quality improvement process and fits well with the development and utilization of practice guidelines. Practice guidelines, as well as risk management, quality assurance, and quality improvement techniques, can help reduce undesirable variation in practice patterns and prevent problems from occurring. Guidelines may be based on different levels of explicitness ranging from subjective judgment to specific outcomes and patient preferences. The use of guidelines and quality improvement mechanisms will enhance the effectiveness of clinical decision making and enable *managed* *care* organizations to work productively with physicians to promote quality.  SO Acta-Psychiatr-Scand. 1992 Dec. 86(6). P 445-9.
 JT ACTA PSYCHIATRICA SCANDINAVICA.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB It was expected from deinstitutionalization that outpatient *care* could replace hospital *care.* But many empirical studies proved that the number of admissions to psychiatric hospitals rose when community-based *care* developed. This might be due to the lack of coordination and cooperation of extramural services. The concept of case management therefore originated in the last few years. In this study the effect of case management on the rehospitalization rate is examined by analyzing the data of 4 social-psychiatric services responsible for defined catchment areas. During the evaluation period of 2.5 years, 162 patients dismissed from psychiatric hospitals were referred to those services. For each of these index patients a matched control patient was identified, each identical in diagnosis, sex, age, living conditions and number of previous inpatient episodes. The results of a survival analysis show that there are no significant effects of case management on the rate of rehospitalization nor on the length of time in hospital in case of a rehospitalization. TI Case management lessons from a public/private partnership to finance long-term *care.*
 SO J-Case-Manag. 1992 Spring. 1(1). P 22-5, 35.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB In June of 1987, Connecticut's State Task Force on Private and Public Responsibilities for Financing Long-Term *Care* for the Elderly released its final report. This Governor's Commission, concluding that neither the private nor the public sector had much short-term hope of solving this difficult problem alone, recommended the creation of a public/private partnership. As this partnership was forged, some unique insights were gained into the functions of case management. This case study shows how case management can help coordinate the private and public roles, but it also raises some research questions which must be tackled before case management can fulfill its promise to help stretch and conserve scarce resources. Author-abstract.

TI The marketplace in health *care* reform. The demographic limitations
of *managed* competition.
SO N-Engl-J-Med. 1993 Jan 14. 328(2). P 148-52.
JT NEW ENGLAND JOURNAL OF MEDICINE.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB BACKGROUND. The theory of *managed* competition holds that the quality
and economy of health *care* delivery will improve if independent
provider groups compete for consumers. In sparsely populated areas
where relatively few providers are required, however, it is not
feasible to divide the provider community into competing groups. We
examined the demographic features of health markets in the United
States to see what proportion of the population lives in areas that
might successfully support *managed* competition. METHODS. The ratios
of physicians to enrollees in large staff-model health maintenance
organizations were determined as an indicator of the staffing needs
of an efficient health plan. These ratios were used to estimate the
populations necessary to support health organizations with various
ranges of specialty services. Metropolitan areas with populations
large enough to support *managed* competition were identified.
RESULTS. We estimated that a health *care* services market with a
population of 1.2 million could support three fully independent
plans. A population of 360,000 could support three plans that
independently provided most acute *care* hospital services, but the
plans would need to share hospital facilities and contract for
tertiary services. A population of 180,000 could support three plans
that provided primary *care* and many basic specialty services but that
shared inpatient cardiology and urology services. Health markets
with populations greater than 180,000 would include 71 percent of the
U.S. population; those with populations greater than 360,000, 63
percent; and those with populations greater than 1.2 million, 42
percent. CONCLUSIONS. Reform of the U.S. health *care* system
through expansion of *managed* competition is feasible in medium-sized
or large metropolitan areas. Smaller metropolitan areas and rural
areas would require alternative forms of organization and regulation

of health *care* providers in order to improve quality and economy.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB BACKGROUND--There is considerable evidence that members of *managed*
care organizations use fewer hospital resources than patients covered
by traditional health insurance. While intensive *care* might seem to
be an unlikely setting for such differences to exist, the
relationship between health coverage and use of intensive *care* has
not been examined. METHODS--We conducted a cross-sectional analysis
of consecutive intensive *care* unit admissions at a regional tertiary
care teaching hospital. Patients in *managed* *care* plans (n = 159) and
with traditional insurance (n = 389) were compared with respect to
length of stay, hospital charges, charges for specific services, and
use of mechanical ventilation. The analysis controlled for severity
of illness, as measured by the Mortality Probability Model, case mix,
and mortality. The whole sample as well as subsamples representing
medical, emergency surgery, and elective surgery patients were
examined. RESULTS--The *managed* *care* group, on average, had short
stays (both hospital and intensive *care* unit), lower charges, and
less use of mechanical ventilation than the traditionally insured
group. Average differences of about 30% to 40% were observed. The
finding held for the whole sample as well as the medical and
emergency surgery subsamples. The differences were more pronounced
in the patients with lowest severity of illness. CONCLUSION--Even in
a setting where there would appear to be relatively little room for
discretion in treatment decisions, incentives associated with type of
health insurance seemed to affect resource use. Author-abstract.

AB *Managed* *care* has become an important subject for health service research and is used increasingly by health *care* payers to control health *care* use and costs. Health services research on *managed* *care* has relevance to the evaluation of case management of persons with substance abuse problems. Two issues in *managed* *care* that are particularly relevant to case management are the lack of explicit, widely accepted criteria for *managed* *care* and the lack of demonstrated cost savings attributable to *managed* *care.* Thorough, systematic evaluative research needs to be done before these issues are well understood. JT ANNALS OF EMERGENCY MEDICINE.
PT EDITORIAL (EDI).
LG English (EN).
AB The nation's current economic conditions, the first time in 60 years that a recession has adversely affected the middle class, might well be the actual trigger mechanism in the passage of a US universal access plan. When enacted, it would provide emergency medicine and other basic physician and hospital benefits to the currently uninsured patients now seen in hospital EDs, in doctors' offices, and as inpatients. It will, thereby, enhance current physician-patient relationships and enable many of the working poor and their dependents to receive medical *care.* Conventional wisdom suggests that such a social insurance plan could significantly reduce the number of routine visits to hospital EDs, assuming that additional,

accessible, and high-quality alternative *primary-care* services are developed. In any case, a universal access plan should improve the percentage of billed charges collected by emergency physicians. The nation's 1,500 third-party payers, with their *managed* *care* strategy, will have difficulty (for the reasons outlined) in micromanaging such external pressures as ensuring high-quality patient *care,* more benefits (including tertiary services), and less cost to the private and public sectors. As there is more micromanaging by third-party payers to reduce expenditures, it will be increasingly difficult for emergency physicians to find specialists willing to accept previously uninsured patients, except at public or teaching environments where the delivery of services to uncompensated patients has been the pattern for several decades.(ABSTRACT TRUNCATED AT 250 WORDS).

LG English (EN).

AB Results of this study demonstrated no significant differences in the frequency of the instrumental use of case management skills between nurses who graduated from the NAMFE program (NAMFE group) and those who were about to enter the program (comparison group); however, there was a significant difference ($p < .0001$ level) in the perceived preparation for performance of these skills between the two groups. Currently, few educational programs provide nurses with the essential knowledge and skills to function in the role of case manager; yet, the job market demands it of them. The program was able to fill the gap between education and service. Although the NAMFE course no longer is available for continuing education credit through the University of Kansas School of Nursing, the course currently is offered as an elective for senior level students and graduate students. Also, the curriculum materials and teaching strategies manuals, developed as part of this grant, and consultations regarding

the use of these materials are available. Author-abstract.

AB "The health *care* system in Minnesota, especially in the Twin Cities
area, is currently undergoing change that can best be characterized
as a consolidation of providers into larger and larger groups
(multispecialty clinics, hospital/physician mergers, and expanded
HMOs and PPOs). These changes are intended to produce economies of
scale, less duplication of services, and better control of costs and
quality of health *care.* Where does this leave the more traditional,
smaller multispecialty or single-specialty practices often referred
to as 'independents'?. How can independent groups respond to these
trends in order to survive in the new health *care* marketplace?".

TI Health *care* reform in Minnesota. Implications for the rural
physician.

SO Minn-Med. 1992 Sep. 75(9). P 11-4.

JT MINNESOTA MEDICINE.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Minnesota's health *care* reform plan (by any name) is a cost-containment bill with provisions to provide health insurance for some uninsured people, to examine quality of *care,* to increase support for rural provider education and migration to rural practice, and to develop state and regional health planning procedures. It is an ambitious bill with very tight time frames, vague language, and heavy reliance on regional commissions and volunteer groups that are just now being established. Will it have an impact on rural health *care?*

Undoubtedly, it will. But somewhere between what the bill says and the desired outcome is a void that physicians can help fill with constructive work and criticism. If physicians do not take the lead, someone else will fill that void--nonphysician providers, legislators, bureaucrats, or consumers. Or the structure could implode, taking all of us with it. Author-abstract.

SO J-Am-Geriatr-Soc. 1992 Oct. 40(10). P 1055-67.

JT JOURNAL OF THE AMERICAN GERIATRICS SOCIETY.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB The objective of this project was to describe geriatric *care* provided under Medicare-risk contracts in HMOs with established Medicare programs. These findings provided the basis for an invitational workshop, sponsored by the National Institute on Aging and the Robert Wood Johnson Foundation, to formulate a research agenda for geriatric *care* in HMOs. The case study method involved site visits to seven HMOs by a physician with expertise in geriatrics, a *managed* *care* specialist, and a program development specialist. Representatives from the HMOs included senior executive officials, physicians recognized for providing and promoting geriatric *care,* research and program development staff, and various clinical staff including pharmacists, geriatric nurse practitioners, nurses, and social workers. The most frequently encountered geriatric *care* programs were categorized by the following six objectives: (1) identifying high risk patients, (2) assessing multi-problem patients, (3) treating multi-problem patients, (4) rehabilitating patients following acute events, (5) reducing medication problems, and (6) providing long-term *care* and home health *care.* Unique programs identified from these site visits included screening methods for new enrollees, approaches to comprehensive geriatric assessment, use of skilled nursing facilities for intensive rehabilitation and postacute *care,* and drug profiling and review. Utilization of geriatric nurse specialists and programs aimed at coordination with social services were pervasive in many of these HMOs. Workshop participants proposed several research and demonstration projects in all six areas. Overall consensus emerged that HMOs with Medicare-risk contracts provide a valuable setting for experimentation in geriatric *care.* Given the current health policy emphasis on *managed* *care* and capitated payment methodologies, geriatric *care* research in HMOs should be a high priority. Author-abstract.

TI Attitudes of dentists toward emerging competencies for health *care*
practitioners.

SO J-Dent-Educ. 1992 Sep. 56(9). P 640-5.

JT JOURNAL OF DENTAL EDUCATION.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Dentists' attitudes about the importance of formal training in a
variety of skills were assessed as a part of the Pew Health
Professions Commission initiative to help health professional schools
prepare for the future. Through a telephone survey with a 54 percent
participation rate, attitudes of a national sample of practitioners
were determined concerning the importance of training in 16
competencies that reflect skills, attitudes, and behaviors identified
by the commission. Most respondents indicated that competency in
treating and preventing disease, practicing ethically, communicating
with patients, applying problem solving techniques, and continuing to
learn were very important. Conversely, less than half of dentists
indicated that competency in managing information, responding to
cultural diversity, supporting community agencies, and working in
managed *care* settings were very important. The opinions of graduates
since 1980 about their own training in the competencies tended to
mirror their ratings of importance. These results demonstrate the
continuing need for dental educators to consider prevailing opinion
of practicing professionals as a part of any evaluation or planning
effort. Author-abstract.

 SO *Arthritis-Care-Res.* 1992 Jun. 5(2). P 111-5.
 JT ARTHRITIS *CARE* AND RESEARCH.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB Over the past 10 years there have been dramatic changes in health *care* financing in the United States, such as Medicare's Prospective Payment System for hospitalized Medicare beneficiaries, and in health services delivery, such as the growth in health maintenance organizations and other forms of *managed* *care.* These changes have occurred largely in response to payors' concerns about the rising cost of health *care.* A study of such changes in financing and delivery, and how specific groups of patients are affected is necessary so that the effects of these changes on patients' health can be determined. We examined the hospitalization rates for patients with musculoskeletal diseases in Michigan from 1980 through 1987. During this period, the overall age-adjusted hospitalization rates decreased 7.0% per year ($p = 0.001$). The decrease occurred less for surgical discharges (6.0% per year) than for medical discharges (8.6% per year) ($p < 0.001$). While these overall trends are of interest, they obscure disease-specific trends that vary significantly from both the overall, and the medical and surgical trends. For example, while surgical discharges, in general declined,

procedures related to major joint and limb reattachment (DRG #209) increased at a rate of 6.3% per year. And while medical discharges in general decreased over this period, discharges for osteomyelitis increased 5.4% per year. The patterns of disease-specific trends offers insight into the possible causes for these changes. Finally, it is important to understand the epidemiology of hospital use to evaluate the effects of new medical *care* delivery and payment systems on the *care* of subsets of patients. Author-abstract.

AB Doctors in health *care* systems of different types are coming under increasing pressure to take on active roles in management. Mounting concern among governments over the escalating costs of health *care,* coupled with a desire to improve the quality of *care* and render services more responsive to user preferences has resulted in management being viewed as offering an effective means of tackling these issues. Until recently, the favoured strategy was to strengthen management in order to curb doctors' discretionary decision-making. There is now a shift towards creating managers out of doctors with all that this implies for the future shape of health services. There are also issues about the training and development required for a management role, the stratification of roles within the medical profession, and the future status of lay, or non-medical managers. The paper reviews the debate about doctors and managers and their distinctive value bases. It suggests that doctors can be involved in management as managers at two levels--meso and micro--and considers the issues raised at each level. The paper presents an analysis of the wider context in which the debate about doctors as managers is taking place. The main thesis put forward is that far from managers incorporating doctors, the end result may prove to be the other way round with 'provider capture' of the management agenda in health services a distinct possibility. In contrast to managers, doctors retain enormous public respect and support. As long as it is so doctors will remain powerful stakeholders in defining and controlling the shape and range of health services available. Their active involvement in management could lead to a strengthening of their position. It is argued that, paradoxically, this could make it more difficult for governments to challenge doctors' work practices. Medicine's traditional preoccupations and its resilience to change are likely to remain as strong as ever thereby disappointing advocates of a health and social *care* system located in a broader policy framework which emphasises health gain and a holistic approach

to health. Author-abstract. 37 Refs.

 AB The participation of physicians in health *care* management has
 followed different paths in developed and developing countries.
 However, we can say that in most of the countries the physicians have
 had cyclical patterns of participation and withdrawal from health
 care management. It is readily apparent that these patterns are
 different in each country. We propose to take into account three
 different levels of analysis in which different factors interact to
 define the country specific pattern of physician involvement in
 health *care* management, as well as to assess the international
 convergence and divergence paths on physician participation. We
 present here a conceptual framework that could facilitate the
 analysis of this theme under a comparative perspective. We start by
 discussing a conceptual framework of the determinants of physician
 participation in health *care* management. Then, we assess the current
 trends and perspectives in both developed and Latin American
 countries of physician participation in health *care* management.

AB The emergence of *managed* *care* organizations offers many opportunities, challenges, and threats for nursing and nurses. The goal of these organizations (ensuring maximum value from resources used) is congruent with the basic philosophy of nursing, which focuses on the total needs of the patient, not just disease, and on maintaining the health of the individual to minimize the need for expensive health *care* services. Within the structure of *managed* *care,* however, there is also a need for strong professional advocacy to ensure that the needs of the members are adequately met as the organization strives to maintain costs. In meeting the needs of the organization and of the members, the nurse also plays an important role in managing the resources used in producing health *care* services. Author-abstract.

JT JOURNAL OF THE NATIONAL MEDICAL ASSOCIATION.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB The period in which we practice medicine is unprecedented in terms of

the enormous changes that are taking place within the profession. Perhaps foremost among the changes is the manner in which the practice of medicine is organized. Historically, over the last 30 years we have witnessed the transition of substantial proportions of physicians as solo practitioners to professionals employed in one form or another by institutional management *care* systems. Further, from all indications, this change is continuing unabatedly. There are now more than 600 health maintenance organizations (HMOs), and their enrollment rates have been steadily increasing. More than 60 million Americans or about 30% of the insured population receive their medical *care* through HMOs and preferred provider organizations (PPOs). Moreover, it is estimated that in the year 2000, 90% of all Americans will be receiving their medical *care* from *managed* *care* systems. Clearly, the driving force behind these changes is the desire of third-party payers and the public at large to control *health-care* costs. We, of course, share this goal and are committed to working with the public and private sectors to accomplish this aim. Deborah L. Scott, director of the Wayne County Patient *Care* Management Systems, writes about HealthChoice, a model *managed-care* program in Detroit, Michigan. Ms Scott's article is being published in lieu of the President's Column. Author-abstract.

AB The dramatic changes in the United States' health *care* system during the last decade have sparked increasing interest in physician-executives. These executives, skilled in both clinical medicine and health *care* management, can be found in hospitals, *managed* *care* organizations, group practices, and government institutions. This paper outlines the physician-executive's roles and the development process. The remarkable growth in the number of physician-executives is expected to continue as they demonstrate their abilities to help health *care* providers expand ambulatory

services, facilitate provider-physician relationships and physician recruitment, and lend expertise in quality improvement and risk management issues. Author-abstract. 20 Refs.

in a program for the severely mentally ill.
SO Community-Ment-Health-J. 1992 Aug. 28(4). P 281-91.
JT COMMUNITY MENTAL HEALTH JOURNAL.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Ethnic differences in rehospitalization were examined in a program of
intensive services for severely mentally ill hospital recidivists.
The purpose was to determine whether ethnicity-related differences in
psychiatric admissions observed in national data would appear among
clients at great risk for hospitalization but enrolled in a program
of *case-managed* *care* to promote community adjustment and tenure.
After accounting for differences in prior emergency visits and
hospitalizations as well as sociodemographic and clinical
differences, blacks were found more likely than whites to visit the
psychiatric emergency room and to be hospitalized. The marked needs
of the severely mentally ill and the intention to address these needs
with services did not obviate the continuing importance of racial
differences in explaining reliance on inpatient sources of *care.*

program for elders.

SO Public-Health-Rep. 1992 Jul-Aug. 107(4). P 417-26.

JT PUBLIC HEALTH REPORTS.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB There is little information on how best to provide health promotion and disease prevention services to elderly persons. This paper reports participants' perceptions of the effectiveness of a health promotion program consisting of health education classes and case management services. A single-group, posttest only design was used for the county-wide program, which operated independent of participants' primary *care* physicians. Each person received a thorough screening evaluation, was invited to health education classes, and was assigned a case manager for a 2-year health promotion period. Community residents 64-71 years of age were recruited; 475 entered the study, and 378 (79.6 percent) completed the followup evaluation interview. Only one-third of the participants attended at least one class, but a majority of those attending each class rated it very or extremely effective in increasing knowledge. To determine the effectiveness of the case managers, each participant identified the three health problems that were of greatest concern to him or her and indicated which of these priority problems were discussed with the case manager. Discussion with the case manager was significantly associated with continuing to see a personal physician for the problem, following the physician's recommendations, the problem's being under control, and the problem's improving over the 2-year followup. The classes and case management services benefited the participants who used them. How to best deliver these services to the target group needs further study. Author-abstract.

JT JOURNAL OF PUBLIC HEALTH POLICY.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB The current turbulence characterizing the health sector has engendered a limited number of state-level experiments to provide health services for the nation's 37 million uninsured. The issues and challenges generated by each program's design and implementation vary. By examining the experience of one such state program, the Washington Basic Health Plan, in some detail, this paper contributes to the policy debate regarding the possible range of solutions available to address the issue of "the uninsured." By analyzing the array of design choices available at the time the program was enacted, and why certain options were chosen rather than others, this paper points to the complex interaction of political dynamics, public policy development, and program implementation. PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).
LG English (EN).
AB Recent literature on caring for people with serious mental illnesses
reflects a growing belief in the effectiveness of case management
services for this population. This article reviews recent outcome
studies on case management to assess the extent to which prevailing
claims that it is effective are supported empirically. Based on this
review, the author concludes that the hypothesis that case management
is effective remains plausible, but conclusive claims that its
efficacy has been empirically demonstrated are premature. The
outcome studies reflect diversity and ambiguity in the ways case
management is conceptualized and implemented, problems in the

research methodologies employed, and inconsistencies in outcomes.
Consequently, implications for further research are drawn.

AB This article examines a case study of one homeless mentally ill woman
in New York City to show the differing perspectives on mental illness
among mental health consumers, family members, mental health
professionals, and advocates. Different issues emerge, and different
priorities for *care* become clear. The social worker as case manager
must design intervention strategies based on these differing
perspectives, a crucial challenge for the profession. This article
reviews the current literature on case management and suggests a
holistic approach that better meets the needs of mentally ill people,
their family members, and the community. Author-abstract.

 LG English (EN).
 AB The Health Insurance Association of America advocates joint efforts
 by federal and state governments and the private sector to achieve
 the goal of universal access to health *care.* It recommends several
 changes in the small employer market to provide greater
 predictability and protection to those insured, including
 establishment of private, not-for-profit reinsurance organizations
 authorized by the states. State risk pools for uninsurable
 individuals who are not part of an employer group are also proposed.
 The federal government role would include expanding Medicaid
 eligibility and exempting all insured plans from state mandated
 benefits. HIAA's proposal also stresses the continued growth and use
 of *managed* *care* programs. Author-abstract.

 AB Data from 9,055 adult intakes performed over two and a half years of
 a *managed* mental health *care* demonstration project in a large U.S.
 city were used as indirect measures of quality of *care.* The level of
 care to which patients were initially assigned was examined in
 relation to the patients' clinical status as judged by both *managed*
 care case managers and treatment providers. During the period,
 assignment to inpatient *care* of patients in almost every clinical
 category decreased. The decrease seemed to reflect a policy decision
 to limit use of all inpatient services rather than a selective
 elimination of unnecessary hospitalization. Case managers rated a
 smaller proportion of patients severely disturbed, partial
 hospitalization was rarely used as an alternative to inpatient *care,*
 and detoxification services were increasingly used as an inpatient
 alternative. Although these data reinforce common beliefs about
 managed *care,* the quality of *managed* *care* programs can be accurately
 assessed only with data collected specifically for evaluation
 purposes. Author-abstract.

TI Impact of case management on hospital charges of PWAs in Georgia.
SO *J-Assoc-Nurses-AIDS-Care.* 1992 Apr-Jun. 3(2). P 24-31.
JT JOURNAL OF THE ASSOCIATION OF NURSES IN AIDS *CARE.*
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB To determine the effects of case management in controlling hospital based costs for persons with AIDS (PWAs), a retrospective review of records of deceased PWAs was performed. The study compared diagnosis-to-death hospital charges for PWAs who received *care* under a *care* management model (n = 60) with PWAs receiving *care* within a non-case *managed* approach (n = 60). Hospital charges were adjusted for inflation. PWAs receiving *care* within the case *managed* model had significantly lower hospital-based charges than the non-case *managed* group. Additionally, PWAs in the case *managed* group lived significantly longer between HIV diagnosis and death, and lived longer between their first AIDS-related hospital admission and death. Author-abstract.

AB The development of effective treatment programs for dual diagnosis
patients is in its initial stages, hampered by a variety of clinical,
theoretical, administrative, and even sociopolitical obstacles.
These patients are difficult to engage and treat effectively using
standard systems of *care.* The Dual Diagnosis Treatment Program at
the Brentwood VA Hospital integrates treatment for both stimulant
abuse and chronic psychosis within one comprehensive program,
emphasizing continuous treatment teams, optimal pharmacological
management, behavior-shaping strategies, skills-training techniques,
and assertive case management. The combination of these treatment
approaches within one program appears to have helped some patients in
our preliminary, one-year experience. Future publications will
describe results from controlled outcome comparisons of DDTP with
customary VA *care.* Author-abstract.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB The origins and evolution of psychiatry as a medical discipline since
the end of the 18th century have been influenced by society's beliefs
about the 'nature of man', the dominant forms of social organisation,
and the level of technology which could be mobilised to modify human
behaviour. These are also the themes from which politics develop.
Throughout the past two centuries and up to the present day, two
distinct streams can be traced in the political history of
psychiatry: first, psychiatry as social control of deviance; and
secondly, psychiatry as advocacy of the 'right to be different'. The
'third psychiatric revolution' which is now in progress in many parts
of the world has been inspired by the second set of beliefs. It has
already produced positive effects on the quality of life of many

patients but is also experiencing certain setbacks. The extent to which the new approach to mental health *care* delivery will benefit patients and society depends not so much on psychiatry as a discipline as on the perceptions and actions of politicians.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Differences between 24 female and 35 male clients were assessed at
entry into an intensive case management program serving homeless
shelter residents and again nine months later. Both men and women
were socially isolated, with small social networks and severe
deficits in social functioning. Histories of homelessness were
similar for both genders, and there were no gender differences in
psychopathology at baseline or follow-up. At entry into the program
women had higher levels of social skills, larger and more supportive
networks, and better housing conditions than men, but these
differences disappeared after the subjects spent nine months in the
program. Inadequate living conditions may have contributed to the
more negative initial picture for men. Although there were more
similarities than differences between the men and women in this
sample, more research on gender differences is needed to design and
evaluate programs for homeless mentally ill persons.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB A small number of multi-problem, service-resistant individuals in every metropolitan community consume extraordinary amounts of human service at great cost to publicly-funded agencies with less than satisfactory benefit to the individual. This paper describes an innovative collaboration among mental health, alcohol/drug treatment, corrections, forensic, and social and housing agencies to provide more effective services at less cost. The theory of action was that (1) inter-agency communication and (2) external controls developed by core service agencies increase the efficacy of treatment and reduce the cost of caring for multi-problem clients. Agencies refer clients to the Multi-Service Network who are then screened for problematic multi-agency involvement. Case conferences result in individual service plans. Three illustrative cases are described and the results of two evaluative studies summarized. Cost of *care* for clients appears to have been reduced. Agencies appear to have benefited from improved information and communication. Clients' behavior was stabilized by external controls and more adequate attention to their needs. Author-abstract.

TI Case management and quality of *care* for diabetic patients.
SO *Diabetes-Care.* 1992 Mar. 15 Suppl 1. P 59-61.
JT DIABETES *CARE.*
PT JOURNAL-ARTICLE (ART).
LG English (EN).

AB Increasing clinical demand for medical services in an environment of limited financial resources to reimburse for such services has lead to the evolution of case management processes. They may be defined as processes that help achieve the best possible clinical outcome for a patient at a cost that represents the best value to the patient and benefit plan. The most responsive and sensitive execution of a case management process is one that includes a high level of physician peer review. This type of case management may enhance the quality of *care* rendered to diabetic and other patients. *Care* that is neither necessary nor appropriate cannot be considered quality, no matter who renders it, nor how good the outcome. A case management process that focuses on medical necessity and seeks flexibility from patients, physicians, providers, and payors can help to maintain appropriate high-quality *care* with costs that, over time, deliver value to all participants in the process. The execution of, and the elements contained within, a clinically sensitive case management process is briefly discussed. Author-abstract.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Since 1965, when the Medicare and Medicaid programs were established by amendments to the Social Security Act, there has been an evolution from internal utilization review of hospital *care* to internal and external review of quality assurance. Hospitalizations for diabetes as a primary diagnosis have decreased over this period, suggesting that more diabetes *care* is delivered as outpatient *care* and is therefore not subject to quality assurance review. Although it is difficult to discern the effect of quality assurance programs and case management on the quality of diabetes *care,* it is certain that these programs will have a major influence in the future. Author-abstract.

 SO Acad-Med. 1992 Apr. 67(4). P 266-70.
 JT ACADEMIC MEDICINE.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB This paper describes the ongoing need for physician executives and
 reviews current opportunities for training physicians in management.
 The authors discuss existing sources of funding and highlight one
 management training program that uses various mechanisms of a new
 funding model that can increase the number and diversity of learning
 opportunities, not only in management but also in all disciplines
 where training traditionally has been underfunded. The basic
 mechanism of this new model is as follows: a privately funded program
 uses a locum tenens arrangement whereby a physician fellow works in
 a community-based private practice in order to produce both
 compensation for work done and funding for training at an academic
 institution. Finally, the authors suggest that academic institutions
 and *managed* *care* organizations might consider such a model as one
 means of using clinical income to expand management training within
 the contexts of their existing academic missions and patient *care*
 commitments. Author-abstract.

AB Transcultural nursing should be the main focus of the nurse in any setting. Increased mobility of society demonstrates the need to understand anthropologic and cultural differences. The Valley provides a laboratory in which transcultural nursing can be examined more closely. Cadena recommends that MA nurses remain open to personal feelings generated by relationships with MA patients. The astute nurse assesses each patient's level of assimilation and provides *care* based on the findings. Comprehensive communication and patient and family participation are the keys to successful transcultural nursing. Sensitivity to modesty and pride translates into professional understanding of holistic needs rather than humiliation and alienation of the patient. At VBMC, these concepts are translated into working systems through the UACs and the *bedside-managed* *care* delivery system. Author-abstract.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB BACKGROUND. The professional literature suggests that changes toward
the bureaucratization of medical practice have led to increasing job
dissatisfaction, especially in primary *care.* To investigate this
claim, we surveyed physicians in Dane County, Wisconsin, who practice
in a bureaucratic setting. Dane County has experienced essentially
a demise in independent practice, ie, most physicians practice in
organizational settings where expenses and total patient income are
pooled. About 85% of physicians have joined one of the six competing
health maintenance organizations (HMOs). METHODS. In 1986 all 850
physicians in Dane County were surveyed to determine their

perceptions of clinical freedom, satisfaction with income, status in their profession, autonomy, resources, and professional relations, and their overall satisfaction. RESULTS. We found that over 69% of primary *care* physicians were very satisfied or satisfied with their practices overall compared with 68% of physicians in all specialties. Differences between family practice and other primary *care* specialties were not statistically significant. Our regression analysis showed that only for satisfaction with income were responses from primary *care* physicians significantly different from those of physicians in surgical specialties. Perceptions of clinical autonomy and specific organizational settings were more important to predicting satisfaction. Also, age and sex contributed to differences in satisfaction with resources and status, respectively. CONCLUSIONS. We conclude that satisfaction can be fairly high for primary *care* physicians in bureaucratic settings similar to that of Dane County. Author-abstract.

TI Medicaid prenatal *care:* a comparison of use and outcomes in fee-for-service and *managed* *care.*

SO Am-J-Public-Health. 1992 Feb. 82(2). P 185-90.

JT AMERICAN JOURNAL OF PUBLIC HEALTH.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB BACKGROUND. To control rising costs, state Medicaid agencies are enrolling recipients in *managed* *care* health plans (MCPs). We performed this study to assess this policy's impact on accessibility and outcomes of Medicaid-funded prenatal *care.* METHODS. We performed a retrospective, controlled study with three cohorts: a study group of 1106 Medicaid recipients enrolled in three MCPs, a matched comparison group of 4830 recipients receiving *care* in the fee-for-service (FFS) system, and a second matched comparison group of 4434 non-Medicaid enrollees of the same MCPs. Data on prenatal *care* use and birth outcomes were obtained through linkage of claims and discharge files with birth certificate files. RESULTS. Medicaid recipients enrolled in MCPs used prenatal *care* similarly to those in the FFS system and showed equal or modestly improved birth-weight distributions. However, Medicaid MCP enrollees showed poorer use of prenatal *care* and birth outcomes compared with non-Medicaid enrollees of the same plans. CONCLUSIONS. Enrollment in MCPs has a neutral or small beneficial effect on the prenatal *care* received by the Medicaid

population. However, providing financial access and modifying the system of *care* for this population did not result in parity with the general population. Author-abstract.

SO Pediatrics. 1992 Feb. 89(2). P 183-92.

JT PEDIATRICS.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Anecdotal evidence suggests that children's access to pediatric subspecialty and inpatient *care* is hampered by referral barriers imposed by *managed* *care* systems. To identify such barriers and determine how they affect the referral process, a sample of American Academy of Pediatrics Fellows (n = 1598) was surveyed. The response rate was 79.1% (n = 1264). Of those pediatricians in direct patient *care* (n = 956), 71.4% participated in a *managed* *care* plan. Pediatricians referred patients in *managed* *care* systems somewhat less frequently than in traditional pay systems: 8.7% and 6.9% referred *managed* *care* patients to subspecialists and inpatient *care,* respectively, less often. More than 20% and 10% of pediatricians with patients in *managed* *care* systems had at least one referral to subspecialist *care* and inpatient *care,* respectively, denied in the previous year. Pediatricians experienced more barriers in preferred provider organizations than in health maintenance organizations. These data suggest that utilization management programs, such as those used in *managed* *care* systems, may limit necessary access to pediatric subspecialty and inpatient *care.* Author-abstract.

Receiving Information...\\-|\\-|\\-| To ensure fairness, objectivity, and timeliness in the review process, we routinely request three reviews. Therefore, authors must submit four copies of each manuscript. All manuscripts must conform to the instructions to authors; those that do not will be returned without review.

All manuscripts must be typed, double-spaced, in English. Type the article on white paper, 216 x 279 mm (8.5 x 11 in) or ISO A4 (212 x 297 mm), with margins of at least 25 mm (1 in). Type only on one side of the paper. Number pages consecutively, beginning with the title page. If the manuscript is accepted for publication, a computer disk copy must be submitted along with two hard copies of the revised manuscript. Corresponding authors will receive 200 free reprints after publication.

Organization of Manuscripts

Research articles are full-length manuscripts reporting scientific research and discovery in the broad field of environmental health and may come from any field of scientific research. Criteria for publication are weighted toward quality and environmental significance.

Title Page: List title, authors (first or second names spelled out in full), full address of the institution where the work was done, and affiliation of each author. Indicate author to whom galley proofs and reprints should be sent (include telephone and FAX numbers).

Second Page: Provide a short title (not to exceed 50 characters and spaces) that can be used as a running head. List 5 to 10 key words for indexing purposes. List and define all abbreviations. Nomenclature and symbols should conform to the recommendations of the American Chemical Society or the International Union of Pure and Applied Chemistry (IUPAC). Include acknowledgments and grant information.

Abstract: Place a double-spaced abstract on the third page. The abstract should not exceed 250 words. The abstract should state the purpose of the study, basic procedures, main findings, and the principal conclusions. Emphasize new and important aspects of the study or observations. The abstract should not include details of materials and methods or references.

Introduction: Begin the Introduction on a new page. State the purpose of the research and give a brief overview of background information. Do not include data or conclusions from the work being reported.

Methods: Begin on a new page. Describe the materials used and their sources. Include enough detail to allow the work to be repeated by other researchers in the field or cite references that contain this information.

Results: Begin on a new page. Present your results in logical sequence in the text. Do not repeat materials and methods, and do not repeat data in tables or figures. Summarize only important observations. Results and Discussion may be combined if desired.

Discussion: Begin this section on a new page. Emphasize new and important aspects of the study and the conclusions that follow. Relate results to other relevant studies. Do not simply recapitulate data from the Results section.

References: Begin this section on new page. References are to be numbered in order of citation in the text and should be cited in the text by number in parentheses. The style for references is as follows:

Journal Article:

1. Canfield RE, Connor JF, Birken S, Kirchevsky A, Wilcox AJ. Development of an assay for a biomarker of pregnancy in early fetal loss. *Environ Health Perspect* 74:57-66(1987).

Book Chapter:

2. Lohman AHM, Lammers AC. On the structure and fiber connections to the olfactory centers in mammals. In: *Progress in brain research: sensory mechanisms*, vol 23 (Zotterman Y, ed). New York:Elsevier, 1967;65-82.

Books:

3. Harper R, Smith ECB, Land DB. *Odour description and classification*. New York:Elsevier, 1968.

Editor as Author:

4. Doty RL, ed. *Mammalian olfaction, reproductive processes, and behaviour*. New York:Academic Press, 1976.

Report:

5. NCTR. Guidelines for statistical tests for carcinogenicity in chronic bioassays. Biometry technical report 81-001. Jefferson, Arkansas:National Center for Toxicological Research, 1981.

Abbreviate journal names according to Index Medicus or Serial Sources for the BIOSIS Previews Database. List all authors; do not use et al. in the bibliography. Include the title of the journal article or book chapter and inclusive pagination. References to papers that have been accepted for publication but have not yet been published should be cited in the same manner as other references, with the name of the journal followed by *in press*. Personal communications, unpublished observations, manuscripts in preparation, and submitted manuscripts should not be listed in the bibliography. They are to be inserted at appropriate places in the text, in parentheses, without a reference number.

Figures and Legends: Four sets of publication-quality figures are required. Graphs and figures should be submitted as original drawings in black India ink, laser-printed computer drawings, or as glossy photographs. Dot matrix computer drawings are not acceptable as original art. Graphs and other drawn figures will be reproduced as submitted and will not be redrawn. The style of figures should be uniform throughout the paper. Letters, numbers, and symbols must be drawn to be at least 1.5 mm (6 points) high after reduction. Choose a scale so that each figure may be reduced to one-, two-, or three-column width. Identify all figures on the back with the authors' names and figure number; indicate TOP. Color figures will be considered for publication if the color facilitates

data recognition and comprehension.

Figure legends should be typed on a separate page following the references. Legends should be numbered with Arabic numerals.

Tables: Each table must be on a separate page. Tables should be numbered with Arabic numerals. General footnotes to tables should be indicated by lowercase superscript letters beginning with a for each table. Footnotes indicating statistical significance should be identified by *, **, #, ##. Type footnotes directly after the table. Complex tables should be submitted as glossy photographs.

Chemical Structures, Chemical Equations, and Mathematical Equations: To avoid problems with typesetting, structures and equations should be submitted as original drawings or as glossy photographs.

Computer Disks: Electronic copies of initially submitted manuscripts are not required. Revised manuscripts resubmitted after acceptance for publication must be sent in electronic form together with two hard copies. Submission of a computer disk is not absolutely necessary for publication of your manuscript; however, publication will be facilitated if a disk is included.

Submit electronic formats on 3.5" disks suitable for reading on either PC or Macintosh platforms. Macintosh is the preferred platform, although PCs are acceptable. The file should contain all the parts of the manuscript in ONE file. Complex tables, chemical structures, figures, and drawings should be submitted separately as glossy photographs as discussed above.

Label the outside of the disk with the title of the manuscript and the authors. Name the computer used (e.g., IBM, IBM compatible, Macintosh, etc.) and the operating system and version (e.g., DOS 3.3). Identify the word processing program and version (e.g., WordPerfect 5.1). We can convert the following programs:

| | |
|--------------------------|-----------------------------|
| Ami Pro v. 1,2 | MultiMate Advantage v. 3 |
| AppleWorks GS WP | MultiMate v. 4 |
| AppleWorks WP v. 2.1,3 | OfficeWriter |
| DCA-RFT (DisplayWrite) | Professional Write |
| FrameMaker MIF v. 2,3 | RTF (Rich Text Format) |
| MacWrite II | WordPerfect Mac v. 1,2,2.1 |

| MS Works WP PC v. 2 | WriteNow NeXT |
| MS Works WP Windows | XYWrite III |

Brief reports are short, original articles, generally of a novel nature. The total length of the manuscript, including abstract, figures, references, and tables, should not exceed 12 pages. Begin with the title page, second page, and abstract as described for research articles. The abstract should not exceed 150 words. Begin the text on page 4 but do not separate the text into

Introduction, Methods, Results, and Discussion; include all parts in a continuous body of text. Keep your descriptions of materials and methods as brief as possible. Begin the body of text with a brief introduction. Handle results and discussion together in the body of the text. References, abbreviations, figures, and tables should be handled as described for research articles.

Research Advances are concise articles intended to address only the most recent developments in a scientific field. Lengthy historical perspectives are not appropriate. Begin with the title page and continue as described for research articles. References, abbreviations, figures, and tables should be handled as described for research articles. Clarity of presentation is of primary importance and the use of color figures is encouraged. Include a photograph (black and white or color) of the author together with a brief biography. If multiple authors or groups are involved then up to three biographies with photographs may be included.

Innovations are short articles that describe novel approaches to the study of environmental issues. Prepare initial pages as described for Research Advances including a brief abstract. Maintain text in a clear and precise manner and wherever possible include color photographs to illustrate strategy and clarify conceptual problems. Some degree of speculation regarding the potential usefulness of a new technique or novel process in other areas of environmental health may be included.

Commentaries are short articles offering ideas, insight, or perspectives. Begin with a title page and second page as described for research articles. Include a brief abstract.

Reviews & Commentary are brief, up-to-date, narrowly focussed, review articles with commentaries offering perspective and insight. Begin with a title page and second page as described for Research Articles. Include an abstract and handle references, tables, figures, and abbreviations as described for research articles.

Meeting Reports should not exceed 2400 words in length. Begin with the title of the meeting and authorship of the report and on the same page continue with the text (double-spaced). Detail when and where the meeting was held, how many people participated, who sponsored the meeting, and any special organizational arrangements. Meeting sponsors and principal participants, such as session chairmen, may be listed in the form of a footnote. Do not couch your narrative in the form of what each speaker said. The report should summarize the contributions of the meeting to scientific knowledge, insight, and perspective. Space in the journal is severely limited so be selective: only the highlights should be mentioned. Novel ideas, perspectives, and insights should be emphasized. Do not describe social aspects of the meeting. Send an electronic and four hard copies.

Environmental Health Perspectives Supplements

Supplement Manuscripts result from conferences, symposia, or workshops and may take several forms. 1) Manuscripts reporting

original research should be formatted as described for either Research Articles or Brief reports, 2) opinions and discussion about a particular topic should be formatted as described for Commentaries, 3) manuscripts reviewing a topic or reporting a combination of review and original research should be formatted as described below for Perspective Reviews.

Perspective Reviews are in-depth, comprehensive reviews of a specific area. They should begin with a title and second page as described for research articles. Introduction and presentation of information should be continuous with specific items and discussion identified by using subheadings. Abstracts, references, abbreviations, figures, and tables should also be handled as described for research articles.

Proposals for the publication of conference, symposium, and workshop proceedings will be considered; however, space is limited. We turn away many excellent proposals simply because we do not have space to publish them.

All proposals are reviewed and examined with a number of specific questions in mind. In developing a proposal, consider the following: Proposals are assessed according to their originality and scientific merit. Is the supplement needed? Is the subject matter timely and potentially useful to workers in the field? What is the environmental significance of the topic being addressed? Is the proposed supplement a complete representation of the field? Are there other aspects that should be included? Does the proposal contain sufficient information for evaluation? Is the presentation clear? Can the organizers integrate the participants into a cohesive unit? Are the contributors appropriate for the topic listed and do they have scientific credibility?

The source of funding is also considered. Scientific objectivity is extremely important, and it must be clear that organizers are not being used to present a bias favored by the funding body. Contributions from an interested party to a conference need not disqualify a proposal, but it is appropriate that the major source of funding be from a disinterested source or that organizational safeguards be set in place to minimize the intrusion of institutional bias.

All proposals must be submitted at least 6 months in advance of the conference. In the publication of conference proceedings, timeliness is essential. Because it takes at least 6 months to publication, no proposal will be considered after the conference has been held.

Submission of Manuscripts and Proposals

Submit all manuscripts and proposals in quadruplicate to:

Editor-in-Chief

Environmental Health Perspectives

National Institute of Environmental Health Sciences

PO Box 12233

Research Triangle Park, NC 27709 USA

In your covering letter please provide assurances that the manuscript is not being considered for publication elsewhere and that all animals used in the research have been treated humanely according to institutional guidelines, with due consideration to the alleviation of distress and discomfort. If the research involved human subjects then a statement must be made to the effect that participation by those subjects did not occur until after informed consent was obtained.

Permission to reprint figures or tables from other publications must be obtained by the author prior to submission of the manuscript.

Finally, a statement must be made indicating that all authors have read the manuscript and are in agreement that the work is ready for submission to a journal and that they accept the responsibility for the manuscript's contents.

Inquiries may be made by calling (919) 541 3406 or by FAX at (919) 541 0273.

Submission of News Information

Environmental Health Perspectives welcomes items of interest for inclusion in the Environews, Calendar of Events, and Announcements sections of the journal. All items are published subject to the approval of the Editors-in-Chief. All submission for these sections should be sent to the attention of:

Associate News Editor

Environmental Health Perspectives

National Institute of Environmental Health Sciences

PO Box 12233

Research Triangle Park, NC 27709

Items submitted for inclusion in the Forum section must not exceed 400 words. Items may be edited for style or content, and by-lines are not attached to these articles. If possible, items should be submitted on computer disk using WordPerfect or Microsoft Word, in straight text without formatting.

Items received for the Calendar of Events will be published in as timely a manner as possible, on a space-permitting basis. Submissions should include all relevant information about the subject, date, time, place, information contact, and sponsoring organization of the event.

Position announcements will be limited to scientific and environmental health positions and will be run on a space-permitting basis. Although we seek to publish all appropriate announcements, the timeliness of publication cannot be guaranteed.

Public information advertisements will be run free-of-cost as space becomes available. All ads are run subject to their appropriateness to the editorial format of the journal. Submissions of advertisements should include full-page, half-page, and quarter-page formats if available. Ads should be camera-ready, black and white positives.

Persons interested in free-lance writing opportunities with

Environmental Health Perspectives should submit a cover letter, resume, and writing samples to the address above. For inquiries call the associate news editor at (919) 541 5377.

TITLE TRANSFORMATION AND MUTAGENESIS

ABSTRACT:

In vitro assays for transformation and mutagenesis represent powerful research tools. Because of the exquisite sensitivity of the experimental systems, possible in large self-contained experiments, low doses of radiation and/or chemicals can be studied that would be quite impractical to detect in human epidemiological surveys, or indeed in most experimental animal systems. The effects of doses of the order of cGy of neutrons or tens of cGy of gamma-rays can be detected and measured. The specific aims of this project fall into four categories. The first, using short-term in vitro cultures of Syrian hamster embryo (SHE) cells involves pragmatic aims of basic importance in radiation protection. We press SPACE for more, q to quit will investigate the inverse dose-rate effect, up to now demonstrated unequivocally only for C3H10 T1/2 cells. It is important to know if this effect is a general phenomenon or confined to one cell line. The in vitro assay will be used to investigate fractionated versus single doses of charged particles of defined LET, while the in utero/in vitro assay will be used for fractionation studies with 6 MeV neutrons. It is also planned to synchronize SHE cells in order to investigate the age response function for the transformational end-point. Second, SHE and C3H 10T1/2 cells will be used to assess the oncogenic potential of photon neutrons. Third, mutations in human keratinocytes and oncogenic transformation in SHE cells will be studied as a function of LET for charged particles in the track segment mode. These data will be fed into the core project entitled hierarchy of radiation effects which attempts to model the biological effects of radiation from patterns of energy deposition to the expression of biological effect. Fourth, we will continue to develop quantitative assays for transformation based on cells of human origin, and estimate the frequency with which radiation induces immortality and transformation. None exist at the present time that are truly quantitative. The goals of this project, therefore, are central to the principal mission of this program project, which is to investigate the biological effects of low doses of radiation.

NEW YORK, NY 10032 PERFORMING
ORGANIZATION: COLUMBIA UNIVERSITY NEW YORK TITLE SMALL DOSES OF RADIATION SUB
TITLE EXPERIMENTAL NANODOSIMETRY ABSTRACT: Much recent biological research supports
the view that close range interactions, of the order of nanometers, can be a dominant
factor in the production of biological damage from ionizing radiation. Until
now, energy distributions at this level could be calculated and inferred, but could
not be measured experimentally. A new instrument, designed and developed in this
Center displays the capability of achieving this goal. This newly designed wall-less
proportional counter is in process of construction. The design is based on a
previously produced conventional walled counter called the UMC (ultra-miniature
counter) which has been shown to be successful in the measurement of single-event
energy Press SPACE for more, q to quit deposition distributions at simulated tissue
equivalent sizes of about 10 nm, far lower than any previously achieved. The new
wall-less design will provide much more accurate spectra for those high LET
radiations whose spectra are most distorted by the so-called wall effect, such
as neutrons. This counter, unlike the UMC, can be calibrated accurately. It will then
be used to provide the first experimental determination of neutron ionization
distributions in nanometer-size sites. With this counter it will be possible to do
measurements on the full range of monoenergetic neutrons available at the RARAF
facility, including the new low energy neutron facility, at site sizes 10 nm and
larger. Measurement of photon neutron contamination from pulsed high energy
radiotherapy beams is also possible. These measurements can in turn supply a
solid experimental base for application of risk assessment in medical and health

physics applications.

CLEVELAND, OH 44106PERFORMING ORGANIZATION: CASE WESTERN RESERVE UNIVERSITYTITLE
RADIATION-INDUCED MODIFICATIONS IN PROTEIN SYNTHESIS ABSTRACT: The central goal of
this research is to delineate at the molecular levelthe structural features of
eukaryotic chromatin which determine thesusceptibility to damage by ionizing
radiation and subsequent repair of theDNA housed therein. The experiments are
designed to test the hypothesis(a) that DNA within relaxed chromatin is more
sensitive to indirectradiation damage and (b) that repair involves a dynamic
participation of anuclear protein complex, perhaps the nuclear matrix. Mammalian
cell lines have been selected because they permit the controlledmodification of
chromatin structure of defined genes or sequences andbecause appropriate genetic
probes are available. Cell culture conditionsPress SPACE for more, q to quitwill be
modified to place the genes in either condensed or relaxedchromatin. The yield of
radiation-induced single-strand breaks andDNA-protein cross-links will be
determined, along with the kinetics ofrepair of those lesions, in the defined genes
as compared to the bulk DNA.Damage will be determined by agarose electrophoresis,
filter binding, andgel filtration chromatography, and the various genes will be
probed byhybridization. The frequency of the particular genes in damaged
vs.undamaged portions of the DNA will permit the calculation of the yield oflesions
in the various chromatin sub-types. The protein complex whichappears to be involved
in DNA-protein cross-linking will be analyzed, andits protein components compared to
those of the nuclear matrix. Acceptorsof poly(ADP-ribose) polymerase will be
identified and localized on activeor inactive chromatin, or the nuclear matrix.
Changes in thepoly(ADP-ribosylation) of the acceptor proteins will be correlated
with therepair of active and bulk chromatin. Until recently, most studies of
ionizing radiation-induced damage in DNAconsidered the entire cellular DNA without
regard for the nucleareenvironment. Modern biotechnology now permits the dissection
of the DNAinto regions which are more or less susceptible to radiation damage.
Thenext advances in this area should come from the detailed analysis of therole of
chromatin structure in determining the sensitivity of DNA toradiation damage and
should assist in providing models of DNA damage andPress SPACE for more, q to
quitrepair for application to clinical radiology.

GRANT SUB TITLE CORE--RADIOLOGICAL SCIENCES ABSTRACT: SUBPROJECT ABSTRACT NOT
AVAILABLE. PARENT ABSTRACT: The University of Colorado Cancer Center is a
"Center" within theSchool of Medicine at the University of Colorado Health Sciences

Center. The Cancer Center goals are: 1) to contribute through coordinated research, clinical, control and educational activities effort to the eventual elimination of cancer as a human health problem, and 2) to provide the citizens of the State of Colorado and the Rocky Mountain region with state-of-the-art cancer research, therapy, control and Press SPACE for more, q to quit educational programs. The Cancer Center serves 6 million people in Colorado and the 7 surrounding states in the Rocky Mountain region. The 190 Cancer Center members have more than \$21 million (annual direct costs) in peer reviewed grants and contracts relating to the cancer problem. Cancer Center members provide care to approximately one-third of the cancer population in the region and enter more than 400 patients on cancer clinical trials each year. The Cancer Center enters an increasing number of patients of clinical trials emphasizing novel trials of the Center and high priority trials of the National Cancer Institute. The majority of cancer educational and control programs in the region are organized by Cancer Center members. The Center provides the major centralized support for these functions through its 10 shared "core" facilities in Biostatistics, Clinical Investigations, Cytogenetics, Fermentation, Flow Cytometry, Histopathology/Tissue Procurement, Laboratory Animals/Transgenic Animals, Macromolecular Resources, Radiological Sciences and Tissue Culture/Monoclonal Antibodies. The Cancer Center has 14 institutional members including the Health Sciences Center schools, affiliated hospitals and other institutions with a primary focus in cancer. The chief executive officers of these organizations form the Cancer Center Board which assures coordination of the cancer effort in the region. The Cancer Center has four major program divisions: Basic Research, Clinical Activities, Education and Press SPACE for more, q to quit Control. The Basic Research and Clinical Activities Divisions are divided into: Immunology; Molecular Biology; Growth Regulation; Cell Surface; Hormones and Cancer; Chromosomes, Mutation and Carcinogenesis; Medical Oncology; Surgical Oncology; Radiation Oncology; Nursing Oncology; and Pediatric Oncology program areas. The primary planning and operational decisions of the Cancer Center are made by the Management Committee which consists of the Director, Deputy Director, Associate Directors and Program Leaders. The University of Colorado Cancer Center has become the leader for the interdisciplinary study of cancer in the Rocky Mountain Region.

10032 PERFORMING ORGANIZATION: COLUMBIA UNIVERSITY NEW YORK TITLE RADIATION CATARACTOGENESIS ABSTRACT: The ERRL of Columbia University is a facility uniquely equipped and staffed to realize its long term commitment to: 1) Assess the cataractogenic risk to the lens from exposure to ionizing radiation. 2) Elucidate the mechanism by which radiation produces cataracts. 3) Exploit the similarity between experimental radiation cataracts and some types of human cataracts to gain insight into the nature of the cortical opacification in general. In adhering to that commitment the proposed studies will involve a greater emphasis on lens damage from 450 MeV/amu iron (56Fe) ions. Inasmuch as 250 kVp X-rays will serve as the reference radiation throughout the studies the investigations will Press SPACE for more, q to quit compliment previous inquiries into X-ray cataractogenesis. Following irradiation, rats will be followed for their lifespans using the Zeiss Scheimpflug

Slit-lamp Imaging System. This will provide, for the first time, an objective, permanent and fully quantifiable record of radiation cataract development and thereby will reduce the ambiguity in the analysis of cataract data generated during this longitudinal study. The investigation will concentrate on the extent and mechanism of the enhancement of cataractogenic potential observed when doses of heavy particles are administered in fractions. The exacerbation of the cataractogenic effect is important, not only from the standpoint of safety, but also because it offers a means to address some fundamental aspects of the response of normal tissues to radiation. We plan to expand our investigations on the cellular basis of radiation cataract development and will concentrate on the target population, the lens epithelium. A number of parameters known to be affected by ionizing radiation will be fully assessed using automated scanning photometry as a function of the dose, time post-irradiation and nature of the radiation. The determinations will include effects of the radiation on the cell cycle, DNA content, cell killing and mutagenesis. These data are critical to press SPACE for more, q to quit an understanding of the mechanism of radiation action on the lens in particular and normal tissue in general. The findings from the proposed studies will contribute greatly to our understanding of cortical cataractogenesis of varying etiologies, including age, and will directly impact the assessment of radiation risk from radiation therapy, occupational exposure and in the space program.

NCI, NIH AWARD AMOUNT..... \$0 PERFORMING ORGANIZATION: TITLE
 CARCINOGENIC EFFECTS OF IONIZING RADIATION ABSTRACT: Dr. Miller and Dr. Beebe have for many years been involved in original investigations on the health effects, especially cancer, of the atomic bombing of Hiroshima and Nagasaki in 1945. Dr. Beebe's current research, in association with Dr. Land, includes a study of primary cancer of the liver in A-bomb survivors, stimulated in part by the high incidence of liver cancer from exposure to alpha radiation from Thorotrast, the radiographic contrast medium. For both Dr. Miller and Dr. Beebe the experience of the A-bomb survivors provides a major resource for consultations, lectures, and articles on radiogenic cancer. Dr. Beebe plays a major role in the development of studies of leukemia and thyroid cancer following the Chernobyl accident in Ukraine in 1986. The Chernobyl press SPACE for more, q to quit studies are directed by Dr. Wachholz, Chief, Radiation Effects Branch. Scientific issues of current interest include: the basis for individual sensitivity to the carcinogenic effect of radiation, the effect of radioiodine exposure on thyroid cancer in children, the contrast between high- and low-linear-energy-transfer (LET) radiation as to their induction of liver cancer, the possible interaction between radiation and hepatitis viruses in producing liver cancer, time-response characteristics of radiogenic cancers, and the influence of dose-rate and dose-fractionation on dose-response characteristics. Dr. Beebe serves as the Departmental Representative on the Science Panel of the Committee on Interagency Radiation Research and Policy Coordination (under the Federal Coordinating Council on Science, Engineering, and Technology, or FCCSET) and has been especially concerned in the effort to reach a Federal consensus on risk estimates for radiogenic cancer. He has also urged that contingency plans be made for research to be carried out in the event of a nuclear disaster in the US.

TITLE RADIATION
INDUCED THYROID CANCER ABSTRACT: The major objective of this research proposal is to
study radiation-induced thyroid cancer by coordinated clinical and laboratory
investigations. The clinical studies are designed to determine the continuing
incidence of radiation-induced thyroid cancer and to evaluate methods of diagnosis
and medical and surgical approaches to treatment. This will be accomplished
by continuing the longitudinal study of patients who received childhood head and neck
irradiation for benign conditions at Michael Reese Hospital. Of the 5,300 patients
who were so treated, 2,000 have been examined in our program and another 1,400 have
been evaluated elsewhere. In this population there is a 36% cumulative prevalence of
thyroid nodules and among those who have had surgery, 36% have had thyroid cancer.
The follow-up of these patients will continue with the following aims: (1) to determine if
radiation-induced thyroid cancer is continuing to occur and, if so, to provide an
estimate of its incidence, (2) since the patients in this population are growing
older, to determine if their radiation-induced thyroid cancers have the same
age-dependent worsening prognosis as seen in the general population, and (3) to
evaluate the treatment methods that have been used. Together these will provide the
information to develop guidelines for the care of persons with a history of
radiation. Our parallel studies will continue on other radiation-induced tumors
which have been found, including those of salivary, neural, and parathyroid
origin. Specific organ doses, as opposed to treatment doses, will be determined
to obtain more precise dose-response curves and risk assessments. Studies
to determine whether there are susceptibility factors for developing radiation-related
neoplasms, especially familial ones, will be extended. Laboratory studies will focus
on the role of serum thyroglobulin in the diagnosis of thyroid tumors. A subgroup of
patients whose clinical evaluations, including thyroid scans, were normal, but who
had elevated serum thyroglobulin levels has been identified. In continuing the
follow-up of these patients and a control group of patients we will determine
the significance of the abnormal determination as a risk factor. This follow-up will
also provide an opportunity to compare scans with ultrasound examinations of the
thyroid. Factors contributing to the heterogeneity of the thyroglobulin molecule,
with relation to thyroid neoplasms, will be studied.

TITLE CANCER RISK IN X-RAY
TECHNOLOGISTS--SECOND SURVEY FOR INCIDENCE ABSTRACT: The University of Minnesota has
been under contract to the National Cancer Institute in evaluating the health of
workers certified by the American Registry of Radiologic Technologists (ARRT) since
February 1982. A 16-page optical scan questionnaire was sent to participants to

obtain information on cancer history, risk factors, work history, and personal medical x-ray exposures. Over 90,000 of the 145,000 technologists under study responded to the full-length questionnaire. An additional 14,000 technologists provided information on their history of cancer, myocardial infarction, and thyroid conditions during an abbreviated telephone interview. Reported leukemias and cancers of the breast, thyroid, and lung were validated by obtaining hospital, pathology, and other reports. Computer linkage with Press SPACE for more, q to quit the records of the nation's largest commercial dosimetry company has Press SPACE for more, q to quit provided at least partial exposure histories on over 85,000 technologists. Press SPACE for more, q to quit Additionally, specific exposure information was obtained from employers for persons who developed leukemia, or cancer of the breast, thyroid, or lung as well as for a random sample of the entire cohort. This second survey is being undertaken to obtain detailed information on cancer incidence during the years since the first questionnaire. Occupational and personal exposures to diagnostic x-rays are already coded and crude estimates of whole-body radiation doses can be made. A second follow-up will enable us to link the occurrence of subsequent cancer with these previous measures of radiation exposure. Incident cancers of the breast and thyroid are of particular interest because mortality data are incomplete.

PERFORMING ORGANIZATION: HARVARD UNIVERSITY TITLE EFFECTS OF
⁶⁰CO RADIATION ON MAMMALIAN CELLS ABSTRACT: The long term goal of this research program is to gain knowledge concerning the mechanisms involved in the response of mammalian cells to ⁶⁰Co radiation, with particular reference to its carcinogenic and mutagenic effects. The approach is a multi-faceted one, and the endpoints under investigation include mutagenesis, malignant transformation, cell survival and the induction of chromosomal abnormalities. The program has a dual purpose: first, to better define the risks of low-level ⁶⁰Co radiation exposure by examining the role of factors such as total dose, dose-rate, LET and the intracellular distribution of dose on the frequency of mutations, transformation; and second, to learn more about the cellular and molecular mechanisms for these effects. The specific aims are: 1) To identify oncogenes activated during the process of malignant transformation by ⁶⁰Co radiation. Transfection of DNA into NIH 3T3 cells will be carried out at regular intervals after irradiation of 10 T1/2 cell cultures; DNA from primary and secondary transfectants will be examined by Southern blotting and reactivity to specific monoclonal antibodies. 2) To examine the direct mutagenic effects of various types of ionizing ⁶⁰Co radiation on the c-Ha-ras proto-oncogene by transfection of the irradiated gene in a plasmid vector. 3) To examine factors involved in the morphological transformation and immortalization of human diploid fibroblasts. A particular focus will be on the study of a DNA fragment derived from the second intron of c-myc which induces specific morphologic alterations in a strain of partially transformed cells. We propose to identify this presumptive regulatory element by deletion analysis and sequencing, and further study its role in transformation. 4) To analyze the molecular structure of spontaneous and induced mutations at the autosomal tk locus in the TK6 human cell line. Appropriate probes will be obtained and restriction fragment or sequence polymorphic markers sought. Molecular biological techniques will be employed in order to determine whether the large-scale changes we have observed involve gene conversion, mitotic recombination or multi-locus deletion events and to estimate their extent. 5) To carry out cytogenetic analysis of mutant clones in order to determine whether large scale DNA structural changes are associated with visible chromosomal abnormalities. Results will be correlated with those of dosage blots. 6) To analyze the spectrum of molecular structural changes induced by different types of ⁶⁰Co radiation including fast neutrons, heavy ions and Auger emitting radionuclides. 7) To continue studies of the relative biological effectiveness for transformation and mutagenesis of low dose, low dose-rate neutron exposure. 8) To investigate the role of microdistribution of dose of high LET ⁶⁰Co radiation within the cell on its biologic effects by use of Auger electron emitting radionuclides. Emphasis will be on mutagenesis in human TK6 cells.

 FRANCISCO TITLE RADIATION GENOTOXICITY FROM THE ^[[7mCHERNOBYL^[[m ACCIDENT
 ABSTRACT: The goal of this program project is to determine whether several newly developed molecular and cellular analytical procedures can be used to measure effects of ionizing radiation on humans. We also will test whether a combination of these measurements made on each individual can provide a set of data that can be used to estimate: (1) the radiation dose received by that individual, (2) his susceptibility to radiation-induced genotoxicity, (3) the relative risk of induced health effects (e.g., cancer) in the exposed individual and/or birth defects in his progeny. Press SPACE for more, q to quit Our method for accomplishing these goals is to simultaneously obtain genotoxicity measurements using four different analytical techniques on blood samples from approximately 800 individuals including people who were exposed to ionizing radiation as a result of the accident at the nuclear power plant in ^[[7mChernobyl^[[m, Ukraine in April-May 1986 and their progeny. Each project in this program project is designed to provide a detailed study of one type of genotoxicity measure: 1. cytogenetics, 2. somatic mutations in the glycophorin A locus, 3. somatic mutations in the hypoxanthine-guanine phosphoribosyl transferase (HPRT) locus, 4. germinal mutations. Cytogenetics is the classical measure of radiation exposure and provides a base line for comparison of other analyses. In addition, a newly developed fluorescence in situ DNA hybridization cytogenetic technique will be tested for applicability. The glycophorin A-based genotoxicity assay has been shown to be a monitor of persistent radiation effects on humans and the kinetics of the response as well as the sensitivity of the assay will be tested. HPRT assay has been applied to several cohorts of radiation exposed people and serves as a clonogenic analysis of somatic mutation effects. The character and persistence of genomic changes that occur in the HPRT locus with human radiation exposure also will be determined. The germinal changes that occur in the HPRT locus with human radiation exposure also will be determined. the germinal mutation study is the first DNA-based analysis to be applied in humans and Press SPACE for more, q to quit can provide an insight into possible genetic consequences of human radiation exposure. Data from the four areas of research will be used in two ways. For each individual assay of somatic cells, a dose-response from ionizing radiation will be generated by comparing the analytical results with physical dosimetry and with immediate biological dosimetry that was

performed by the Soviet medical scientists in 1986 shortly after the
 ^[[7mChernobyl^[[m accident. This should provide a means for interpreting each of the
 bioassays for its capabilities as a monitoring biodosimeter for similar radiation
 exposures (both sensitivity and precision will be determined). In addition,
 the combination of measurements from the four different research areas will allow an
 overall effect of exposure of each individual to be determined. A weighted sum of
 these effects will be derived, and in the future this may serve as an individual
 dosimeter for dose, an indicator for higher susceptibility to damage, and an
 estimator for that individual's risk to develop cancer.

 FRANCISCO TITLE RADIATION GENOTOXICITY FROM THE ^[[7mCHERNOBYL^[[m ACCIDENT SUB
 TITLE CYTOGENETIC ANALYSIS OF ^[[7mCHERNOBYL^[[m VICTIMS ABSTRACT: This project
 seeks to utilize state-of-the-art molecular cytogenetic techniques to determine the
 frequency and persistence of stable cytogenetic damage in peripheral T lymphocytes of
 victims of the ^[[7mChernobyl^[[m nuclear reactor accident. The subjects involved in
 this study fall into two groups: those who received high whole-body doses (ranging
 from ~0.8 to ~6Gy), and those who were exposed more slowly (over a period of one or
 a few days) and received ~0.25 Gy. Fluorescence in situ hybridization
 of chromosome-specific composite DNA probes ("chromosome painting") will be used to
 measure the frequency of stable chromosome aberrations, i.e. translocations. These
 results will be validated against the conventional Press SPACE for more, q to
 quit method of G-banding. In a cross-sectional component of this study, 60 people
 whose exposures range from 0 (matched controls) to the highest surviving doses will
 be examined. Accurate exposure estimates will be made and used as a benchmark
 against which the results of the glycophorin A, HPRT, and germinal mutation portions
 of this Program Project will be compared. The dosimetry will also be used to guide
 the selection of subjects for a longitudinal component of this study. Here, 16
 subjects who span the dose range will be examined for five consecutive years.
 The proposed work will lead to a greatly improved understanding of the
 temporal stability of various cytogenetic anomalies (particularly translocations), the
 extent of clonal expansion following radiation exposure, the effects of dose on
 translocation stability and clonal expansion, and the utility of chromosome painting
 as a reliable and effective biodosimeter following accidental radiation exposure. In
 conjunction with the GPA, HPRT, and germinal mutation efforts of this Program
 Project, this work will lead to a greatly increased understanding of the long-term
 effects of human exposure to ionizing radiation.

 FRANCISCO TITLE RADIATION GENOTOXICITY FROM THE ^[[7mCHERNOBYL^[[m ACCIDENT SUB

TITLE SOMATIC HPRT GENE MUTATIONS IN RADIATION-EXPOSED WORKERS ABSTRACT: Although it is well established that radiation is a mutagen, more information is needed on the consequences of radiation exposure for specific genetic loci in somatic cells of man, and of the variables that may affect these consequences. Central to evaluation of these consequences is the ability to measure genetic damage. Assessment of a variety of types of genetic damage is needed to ensure that both the quantity and character of damage are ascertained. The objective of this project is to evaluate the biosimetric information that analysis of mutations of the hypoxanthine phosphoribosyltransferase (HPRT) gene of human peripheral blood lymphocytes can provide for individuals that were exposed to radiation as a consequence of the Chernobyl nuclear power accident. The frequency of mutation will be assessed by the established in vitro limiting dilution assay of thioguanine-resistant, HPRT-deficient T lymphocytes. The molecular nature of mutations present will be assessed using genomic DNA of mutant clones. Gross alterations of the HPRT gene will be detected by Southern analysis of restriction enzyme digested genomic DNA. The extent of deletion of sequences that flank the HPRT gene on the X chromosome will also be determined. Smaller deletion and insertion events that affect the exons of the HPRT gene will be detected with a multiplex polymerase chain reaction (PCR) analysis; PCR analysis will also confirm the identity of exons affected by gross deletions. These molecular analyses will be applied to multiple mutants per individual for selected subsets of the population to study both interindividual differences in mutation spectra and correlations of the molecular nature of mutation with mutation frequency and exposure history. The molecular analyses will also be applied in a cross sectional mode to one mutant of each member of a larger population to assess whether bias is introduced by studying smaller groups of individuals in detail. The stability over time of the frequency and molecular nature of damage at this genetic locus in lymphocytes will be determined for subsets of the population. By studying individuals who received different doses of radiation following the Chernobyl accident, the relationship between exposure history and mutational responses at the HPRT gene will be determined. In combination with the biosimetry data acquired from the other projects of this Program, these results will advance efforts to assess human risk for somatic and germinal mutation following exposure to mutagenic agents.

 FRANCISCO TITLE RADIATION GENOTOXICITY FROM THE Chernobyl Accident SUB
 TITLE SOMATIC MUTATIONS AT THE GLYCOPHORIN A LOCUS IN RADIATION EXPOSED IN ABSTRACT:
 There are two primary objectives for the glycophorin A-based somatic mutation
 analysis project. The first objective is to determine the magnitude and types of
 somatic mutational damage in individuals due to radiation exposure from the
 Chernobyl nuclear power accident as measured by the glycophorin A (GPA)
 assay. Analysis will be performed on samples from individuals with both high- and
 moderate-dose exposures, and will include measurements of the frequency of both
 hemizygous and homozygous variant erythrocytes. Measurements of the
 frequencies of somatic cell mutations at the GPA locus will be correlated with

different indicators of genetic damage from other programs in the program project to provide a comprehensive analysis of genetic damage in these individuals. The second objective is to determine the utility of the GPA assay as a biodosimeter for large population studies of individuals where physical dosimetry information is not available. Measurements of the dose-response relationship, the minimum detectable dose, and the persistence of induced damage will be used to determine the utility of the GPA assay for dose assessment. Results from the GPA assay will be compared with the results from other biodosimeters in the program project to determine the relative sensitivity, cost, and reliability of the different methods.

 TITLE RADIATION GENOTOXICITY FROM THE ^[[7mCHERNOBYL^[[m ACCIDENT SUB TITLE GERMINAL MUTATION RATE IN RADIATION EXPOSED WORKERS
 ABSTRACT: Significant concern continues to be expressed by both the government and the public regarding the potential of genotoxic agents to increase the germinal mutation rate and, therefore, the incidence of genetic disease in humans. Current estimates of the potential human health risk from gene mutations caused by exposure to mutagenic agents are derived from animal data generated following exposure to high doses of suspected mutagen. Animal data are used because it has not been possible to obtain sufficient data from humans. Molecular techniques for the study of gene structure have potential for Press SPACE for more, q to quit generating significant quantities of data from a mother/father/child triad. These approaches are being developed as tools for estimating the heritable mutation rate in human populations. This project will focus on determining the mutation rate for insertion, deletion and/or rearrangement mutations, the molecular lesions expected to be most the frequent class of event in offspring of radiation exposed individuals. A restriction-enzyme-site-mapping strategy will be employed to screen approximately 1000 loci in each triad. The 750 offspring to be studied will have been born to individuals exposed to significant levels of radiation during the cleanup at ^[[7mChernobyl^[[m. The triads will focus on fathers receiving high doses (>0.25Sv) during short time periods, the group expected to have the highest mutation rate. Appropriate control triads will also be screened. The technology employed in this study will be transferred to our Soviet collaborators for inclusion into future studies in the continuing monitoring of this population. Thus, this study, which will generate a data base of 750,000 locus tests, should be viewed as an initial pilot study in a longer term effort. The study of germinal gene mutations in humans addresses one of the significant issues for man, namely, the component of the genetic burden and health risk transmitted to future generations that is caused by exposure to mutagenic agents. This integrated program of 4 projects will be a model Press SPACE for more, q to quit for future efforts to estimate human risk, using approaches that combine measures of human exposure with the results of predictive tests in model systems to estimate potential increases in human mutation rates and subsequent genetic disease.

 40536 PERFORMING ORGANIZATION: UNIVERSITY OF KENTUCKY TITLE THE SPECTRUM OF MUTATION
 INDUCED BY IONIZING RADIATION ABSTRACT: One of the prices we pay for living in an
 industrial and technological society is exposure to a variety of chemical and
 radiation mutagens. Examples of this exposure are contaminating levels of Cs-137
 remaining from the ^[[7m Chernobyl ^[[m disaster and increased exposure to UV due to
 thinning of the ozone layer. Both events are expected to result in increased numbers
 of cancers. Although it is possible to readily detect this exposure if it occurs at
 high dose, it is far more difficult to detect this exposure if it occurs at low dose
 or if the possibility of exposure is raised after it has occurred. One potential
 means of addressing this problem is to determine the spectrum of mutations induced by
 a specific mutagen and then determine Press SPACE for more, q to quit if this spectrum
 is present in genomic DNA in cells taken from individuals at risk. This grant
 proposal involves using a cultured mouse stem cell system to determine more
 accurately the spectrum of mutation induced by ionizing radiation. The first
 specific aim is to determine the mutational spectrum induced by high dose high and
 low LET ionizing radiation and compare and contrast this spectrum with those spectra
 produced by equally genotoxic doses of UV and an alkylating chemical mutagen, as well
 as with the spontaneous spectrum. Having defined the ionizing radiation spectrum, the
 second specific aim is to determine the lowest possible dose at which all or part of
 this spectrum can be recognized. The third and final specific aim is to determine if
 the ionizing radiation induced mutational spectrum is altered in morphologically
 differentiated cells derived from the stem cells. Such a comparison has not been
 performed previously. The mouse cell lines to be used are unique because they have
 heterozygous deficiencies for the purine salvage gene aprt
 (adenine phosphoribosyltransferase) and because they contain two chromosome
 8 homologs, which harbor the aprt gene, that are distinguishable with a molecular
 analysis. Cells with homozygous deficiencies, which will be induced with the above
 mutagens, will be selected and a molecular analysis used to elucidate and enumerate
 the spectrum of mutations. This molecular analysis will include Southern blots, PCR,
 and DNA sequencing.

COMPUTER AIDED TWO-DIMENSIONAL ELECTROPHORETIC GEL ANALYSIS ABSTRACT: Analytic methods are continuing to be developed and applied using the GELLAB-II software system - an exploratory data analysis system for the analysis of sets of 2D electrophoretic gel images. It incorporates sophisticated subsystems for image acquisition, processing, database manipulation, graphics and statistical analysis. It has been applied to a variety of experimental systems in which quantitative and qualitative changes in one or more proteins among hundreds or thousands of unaltered proteins is the basic analytic problem. Keeping track of changes detected using these methods is also a major attribute of the system. A composite gel database may be "viewed" under different exploratory data analysis conditions and statistical differences and subtle patterns elucidated from Press SPACE for more, q to quit "slices" of an effectively 3D database. Results can be presented in a variety of tables, plots or derived images and on workstations over wide area networks. Substantive GELLAB-II applications include: Ongoing studies of cadmium toxicity in urine (Myrick), Rett syndrome (Myrick), Vermont mercury study (Myrick), serum dioxin study (Myrick), fetal alcohol syndrome study (Myrick) - a new study will be neural tube defects (Myrick); 2D DNA gels for identifying differentially expressed genes (Rogan); investigation of radioactive accidents and fall-out from ¹³⁷Cs (Krekling). In a collaboration with Merrill, we are developing a relational 2D gel interactive disease-protein-spot database system for answering queries relating proteins in plasma, serum, urine and CSF as a diagnostic tool. We continue to explore image conferencing of 2D gel images as well as other problem domains using Xconf. GELLAB-II has been exported to and is being supported at: CDC/Atlanta (Myrick), U. Norway (Krekling), Monsanto Research Labs (Leimgrubber et al.). This year, CDC has been the primary Beta test site for GELLAB-II. Additional changes to help continued collaboration with and exporting of enhanced graphical-interface versions of GELLAB has been actively pursued and is the primary activity this year.

 The National Library of Medicine

(NLM) wishes to provide planning and
 implementation grants to health science institutions that seek
 assistance in integrating their existing scattered databases and
 information systems into a comprehensive networked institutional
 --more-- Press [space] to continue, [q] to quit information management system
 capable of serving clinical, research,
 educational, and administrative needs.

The Integrated Advanced Information Management Systems (IAIMS) program
 described in this Program Announcement (PA) is a substantially revised
 version of the NLMs existing IAIMS program, first announced in 1982.

PROGRAM OBJECTIVES

Background

In 1983 the NLM initiated an award program to provide "assistance to
 medical centers and health science institutions for planning and
 --more-- Press [space] to continue, [q] to quit development projects leading to the
 implementation of Integrated
 Academic Information Management Systems (IAIMS)." The program
 announcement went on to say, "IAIMS are institution-wide computer
 networks that link and relate library systems with individual and
 institutional databases and information files, within and external to
 the institution, for patient care, research, education, and
 administration. The goal is to create an organizational mechanism
 within health institutions to more effectively manage the knowledge of
 medicine, and to provide for a system of comprehensive information
 access."

During the next decade over seventy institutions applied for IAIMS
 grants in one or another of the 3 defined phases, and through FY 1991
 26 awards had been made to 16 institutions. The importance of
 information management today is as great as ever, but the program
 elements as originally defined by NLM deserve re-evaluation. Lessons
 have been learned from a decade of experience; furthermore, the climate
 has changed significantly as a number of institutions made extensive
 investments in information systems in recent years; most importantly,
 the advent of the High Performance Computing and Communications
 --more-- Press [space] to continue, [q] to quit Initiative (HPCC) has dramatically
 enriched the possibilities of
 information transfer, while increasing the complexity of information
 management.

The NLM is the lead biomedical organization in the federal Government's

HPCC initiative. The HPCC program recognizes "that unprecedented computational power and its creative use are needed to investigate and understand a wide range of scientific and engineering 'grand challenge' problems." (1) Some of the problems identified are of obvious interest to biomedicine: National Research and Education Network (NREN), biotechnology, transmission of digital images, intelligent gateways to retrieve information from several life sciences databases, and innovations in educational techniques, among others.

Accordingly, NLM is revising its IAIMS program with:

- o A name change: replacing "academic" with "advanced" recognizes the wide applicability of the IAIMS concept and the need to incorporate new technology
- o Fusion of the old phases II and III (model and implementation) into --more-- Press [space] to continue, [q] to quit one operational phase
- o Changes in the level of support
- o Some modification of the scope and conditions of the grant
- o Incorporation of HPCC into the NLM vision of an integrated information management system.

The Integrated Advanced Information Management Systems (IAIMS) Program

The revised IAIMS program has two phases: A planning phase, and an operational phase.

1. IAIMS Planning Phase

"New" IAIMS planning phase resembles Phase I of the "old" IAIMS. Various models can be used in information systems planning, but all applications should include some form of self-study and allow for certain key elements:

- o A description of the institution's information management resources, current and five-year projection;
- more-- Press [space] to continue, [q] to quit o Development of an institutional information policy that addresses both short-term and long-term goals;
- o Identification of leadership for planning;
- o Broad involvement of clinical and basic science faculty, administration, and students;
- o Specification of desired strategic outcomes;
- o An outline of the planning process, including goals and timetables; and
- o A comprehensive view that considers information needs of patient care, research, education, and administration.

The outcome of planning activities is the development of an institutional Information Management Plan, which should include information resources management policies, an analysis of functions and

responsibilities of major information database managers, and a description of how IAIMS will be developed, organized, and managed.

A total separation between planning and operations is not mandated; institutions vary widely in the information system already in place at the time of application. An institution may, if it wishes, use or --more-- Press [space] to continue, [q] to quit introduce some operational elements during this planning period (for example, an E-mail system.)

The IAIMS planning grant may be for up to \$150,000 per year for one to two years. The grant supports direct costs only; funds are not provided for indirect or overhead costs.

2. IAIMS Operational Phase

Health science institutions that complete the IAIMS planning phase successfully (or can demonstrate a comparably sophisticated information management plan based on their own planning efforts) may apply to NLM for an IAIMS operational phase grant to assist them in implementing the plan. Plans will vary for different institutions, but certain key elements are of interest to all:

A. Essential

- o A plan for developing the institution's information management resources, and the requisite networks;
--more-- Press [space] to continue, [q] to quit
- o A functional Information Management Policy;
- o Designation of leadership with appropriate background and status;
- o A plan for supporting IAIMS after termination of the grant;
- o Timetables for reaching key features of the operational plan;
- o Reasonable timetables for major plan features such as development of the network, organization of the management structure, appointment of the leadership, and post-grant financing plans. The ability of funded institutions to reach such milestones in a timely manner will be evaluated by the NLM when deciding annually on continuance of funding;
- o The ability to provide efficiently bibliographic and related literature pertinent to health care delivery and research. Significant participation by the health sciences library is essential; and
- o Substantial incorporation of one or more elements of HPCC/NREN into the institution's information system. Connection to Internet, for example, is one such element; other examples include collaboration through high speed networks, distance learning, addressing of computationally intensive problems in molecular biology in a distributed environment, visualization techniques, and network-based
--more-- Press [space] to continue, [q] to quit

digital imaging.

B. Highly Recommended

- o A clear relationship to clinical aspects of the health sciences, such as linkage with a computerized patient record, a hospital information system, clinical alert information/distribution systems, clinically relevant expert systems, and/or systems for monitoring quality of care and cost-control; and
- o Incorporation of current NLM objectives such as, connection to national networks, direct access to Medline and/or extensive use of Grateful Med, outreach components which improve information access for health care workers in underserved rural or inner city locations, and in other health care sites affiliated with the applicant.

C. Optional

- o An apprenticeship in IAIMS may be incorporated into the operational plan at the discretion of the applicant, through a position entitled --more-- Press [space] to continue, [q] to quit IAIMS Assistant. An educational program should be described, outlining the credentials of the candidates, the goals and duration of the apprenticeship, the structure of the learning experience, and other relevant material. Personnel, travel and supply costs may be requested up to a total of \$50,000 for each year of the operational phase. Costs for apprentices should be budgeted in accordance with standard institutional policy.

Other Information About the Operational Grant

The operational phase grant application may include an initial period of model development at the discretion of the institution, but a distinct interim period of model-building is not required.

Operational phase grants may be for up to \$500,000 per year for five years, or for up to \$550,000 per year for five years if support for the apprenticeship program is included. Only direct costs are supported.

NLM support for IAIMS at an institution will terminate at the end of the five-year operational phase, and is not renewable.

--more-- Press [space] to continue, [q] to quit

The word "institution" as used in this program description implies that IAIMS will involve all major organizational components of the institution to the extent feasible. The NLM realizes that large differences among medical centers are inevitable, and that at some sites, certain suborganizations may not be suitable for incorporation into the initial IAIMS plan. However, a plan that is restricted to a relatively small fraction of the institution has misunderstood the point of the program, and will not be favorably reviewed.

Reviewers will review the grant applications by considering the following criteria:

- o Appropriateness, originality, feasibility, and relevance of the proposed project to the overall goals and objectives of the RFA.
- o Qualifications, experience and proposed responsibilities of the Principal Investigators and key personnel.
- o Scientific merit and organizational plans for implementing the proposed program.
- o Demonstration of availability of normal and at-risk patient populations.
- o Proposed collaborations among audiologists, otolaryngologists, neonatologists, nursing staff, and other key personnel within the applicant and collaborating institutions; adequacy of documented interest, capabilities, and commitment of all potential participating clinics.
- o Facilities and resources, and the availability of such for this project.
- o Adequacy of proposed overall administrative procedures and inter- and intra-institutional collaborative arrangements.
- o Reasonableness and appropriate justification of the proposed budget.
- o Plans to protect the rights and welfare of human subjects, including appropriate informed consent procedures.

AB We have shown elsewhere that highly non-uniform exposure to ionizing radiation from authentic Chernobyl-released and artificially-produced hot particles (fragments of *nuclear* fuel) transform fibroblastic 10T1/2 cells in vitro effectively. We have also shown that hot-particle exposure leads to mutation and overexpression of the tumour suppressor gene p53 (and some other growth-related genes) in mouse skin in vivo at a high frequency. In the present paper it is shown that hot-particles produced by irradiating natural uranium with slow neutrons, when implanted (immobilized) under the skin of hairless and nude mice, induce epidermal tumours in excess compared with the conventional non-threshold stochastic model of radiation-induced cancer. One explanation for the effectiveness of the hot-particle exposure, under the present assay conditions, is that the same cells in which specific radiation-induced DNA damage is most likely to occur, are forced into sustained mitotic activity in the chronic wound which develops around the radiation source (combined genotoxic and nongenotoxic effects). The results are consistent with a role for cell proliferation in multistage carcinogenesis in mouse skin. Author-abstract.

TI Onset of chromatin fragmentation in chloroma cell apoptosis is highly
 sensitive to UV and begins at non-B DNA conformation.

SO Int-J-Radiat-Biol. 1993 Feb. 63(2). P 207-13.

JT INTERNATIONAL JOURNAL OF RADIATION BIOLOGY.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB UV irradiation induces programmed death, or apoptosis, in rat
 chloroleukaemia cells, a process characterized by typical cell
 morphology, fragmentation of chromatin into units of single and
 multiple nucleosomes, and transcriptional activation of LINE. Our
 study shows that this process is initiated by very low UV doses:
 exposure to one minimal erythema dose (MED, about 200 J/m²), at
 defined wavelengths ranging from 270 to 330 nm, is sufficient. By
 sequencing 100 randomly selected blunt-end chromatin fragments
 (single and multiple nucleosomes) we observed that at an early stage
 of apoptosis the fragmented DNA contains a four-fold excess of both
 long and short interspersed *nuclear* retroelements (LINEs and SINEs).
 A distinct sequence finding was also the observation that fragmented
 DNA is very rich in microsatellites, (CA)_n dinucleotides in
 particular, and in long stretches of homopurine/homopyrimidine
 domains. The present results thus indicate that chromatin
 fragmentation in UV-induced apoptosis begins at non-random locations
 involving non-B DNA conformation, and that the onset of the suicide
 process in chloroleukaemia cells is surprisingly sensitive to UV
 exposure. Author-abstract.

TI SNR and noise measurements for medical imaging: I. A practical
 approach based on statistical decision theory.

SO Phys-Med-Biol. 1993 Jan. 38(1). P 71-92.

JT PHYSICS IN MEDICINE AND BIOLOGY.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB A method of measuring the image quality of medical imaging equipment is considered within the framework of statistical decision theory. In this approach, images are regarded as random vectors and image quality is defined in the context of the image information available for performing a specified detection or discrimination task. The approach provides a means of measuring image quality, as related to the detection of an image detail of interest, without reference to the actual physical mechanisms involved in image formation and without separate measurements of signal transfer characteristics or image noise. The measurement does not, however, consider deterministic errors in the image; they need a separate evaluation for imaging modalities where they are of concern. The detectability of an image detail can be expressed in terms of the ideal observer's signal-to-noise ratio (SNR) at the decision level. Often a good approximation to this SNR can be obtained by employing sub-optimal observers, whose performance correlates well with the performance of human observers as well. In this paper the measurement of SNR is based on implementing algorithmic realizations of specified observers and analysing their responses while actually performing a specified detection task of interest. Three observers are considered: the ideal prewhitening matched filter, the non-prewhitening matched filter, and the DC-suppressing non-prewhitening matched filter. The construction of the ideal observer requires an impractical amount of data and computing, except for the most simple imaging situations. Therefore, the utilization of sub-optimal observers is advised and their performance in detecting a specified signal is discussed. Measurement of noise and SNR has been extended to include temporally varying images and dynamic imaging systems. Author-abstract.

SO Health-Phys. 1992 Nov. 63(5). P 571-3.

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Several radionuclides were identified in the surface air in Finland following a *nuclear* incident in Sosnovyy Bor on 24 March 1992. In addition to gases, the release contained small uranium fuel particles. The radionuclide concentrations were of the same order of magnitude as the concentrations detected in Northern Finland in 1987 after the *nuclear* explosion in Novaya Zemlya (1 mBq m⁻³) but five orders of magnitude smaller than the concentrations during the Chernobyl accident in 1986. The radiological consequences in Finland were insignificant. However, studies show that even a minor release, across the sea and more than 100 km away, can be detected and important information, including the time of the incident and the composition of the release and the burn-up of the damaged fuel, can be revealed by the most accurate radioactivity measurements.

TI Social class and colon cancer survival in Finland.

SO Cancer. 1992 Jul 15. 70(2). P 402-9.

JT CANCER.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB METHODS. Social class differences in colon cancer survival were studied in 3147 patients with colon cancer diagnosed in Finland from 1979-1982. Of these patients, 2969 were eligible for survival analysis. RESULTS. A clear social class gradient in colon cancer survival was detected. The difference in the age-adjusted relative risk of death due to colon cancer between the highest (I) and lowest (IV) social class was 19%. Stage of disease at diagnosis accounted for a substantial proportion of differences in survival, and treatment accounted for the rest of them. Differences in treatment by social class were most apparent among patients with advanced or unknown stage of disease at diagnosis. Controlling for the place of residence had little effect on the survival differences. Delay in diagnosis did not account for the observed differences in survival by social class. Author-abstract.

nuclear energy production.
SO Sci-Total-Environ. 1992 Apr. 114. P 99-112.
JT SCIENCE OF THE TOTAL ENVIRONMENT.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Radiation doses from natural radiation and from man-made
modifications on natural radiation, and different natural
radiological environments in the Nordic countries are summarized and
used as a perspective for the radiological consequences of *nuclear*
energy production. The significance of different radiation sources
can be judged against the total collective effective dose equivalent
from natural radiation in the Nordic countries, 92,000 manSv per
year. The collective dose from *nuclear* energy production during
normal operation is estimated to 20 manSv per year and from
non-nuclear energy production to 80 manSv per year. The increase in
collective dose due to the conservation of heating energy in Nordic
dwellings is estimated to 23,000 manSv per year, from 1973 to 1984.
An indirect radiological danger index is defined in order to be able
to compare the significance of estimated future releases of
radionuclides from a final repository of spent *nuclear* fuel to the
consequences of natural radionuclides in different environments. The
danger index of natural radiological environments will not be
significantly increased by future releases of *nuclear* fuel
radionuclides. Author-abstract.

 JT JOURNAL OF THE OPTICAL SOCIETY OF AMERICA. PART A, OPTICS AND IMAGE SCIENCE.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB The problem of detecting symmetry has been studied by using digitally generated images with random pixel values. The statistical efficiency of humans and a computerized observer, the cross correlator of the image halves, has been evaluated. The efficiency of humans is approximately 100% when the image comprises only a few pixels and is notably better than that of the cross correlator. When the number of pixels in the image is increased, the detectability of symmetry gets better. For human observers detectability saturates, however, on a level corresponding to a modest number of pixels. Human efficiency in detecting symmetry is thus low when the image matrix size is large.  JT INTERNATIONAL JOURNAL OF RADIATION BIOLOGY.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB A detailed study was made of the conditions of exposure of 56 victims of the Chernobyl accident who suffered radiation lesions in the skin. The most typical conditions were experimentally reconstructed in order to investigate the specific characteristics of the distribution of doses to the skin according to depth for different exposure conditions. The absorbed doses at depths of 7 mg cm⁻² and 150 mg cm⁻² were calculated on the basis of measurements with multilayer skin dosimeters. The patients were classified into four groups. Dosimetric characteristics for each group were compared with the clinical pictures to establish the critical factors in the occurrence of lesions. It was demonstrated that the depth-dose distribution of

beta-radiation to the skin is of great influence not only for the early effects of radiation but also for the later effects. Radiation lesions in the skin led to death if the area of the lesions exceeded about 50% of the total body surface, and if the doses to the skin were about 200-300 Gy at 7 mg cm⁻² and more than about 30 Gy at 150 mg cm⁻². TI UV light and ionizing radiations cause programmed death of rat chloroleukaemia cells by inducing retropositions of a mobile DNA element (L1Rn).
SO Int-J-Radiat-Biol. 1990 Feb. 57(2). P 331-43.
JT INTERNATIONAL JOURNAL OF RADIATION BIOLOGY.
PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB The long interspersed repetitive DNA, L1 or LINE, is a class of mobile genetic elements which can amplify in the cell genome by retroposition, i.e. by a mechanism similar to that of retroviruses. We have shown before that in rat chloroleukaemia cells, maintained in suspension culture in vitro, this element is spontaneously transcriptionally activated at about half of the maximal population density. About 24 h later an explosive amplification of the L1 element is seen in DNA: about 300,000 copies are inserted into apparently random locations in the cell genome, thus creating an outburst of lethal mutations. Dead cells display morphological features typical to programmed death. The present results show that UV light and ionizing radiation induce rapid, premature activation of the L1Rn element during the fast exponential growth of chloroleukaemia cells, and that also this exogenously induced activation is followed by programmed cell death. Transcriptional activation of the L1Rn element can be very strong after the UV exposure: at least 70-fold. Severe hyperthermia, lethal to the cells, does not lead to L1Rn activation (actually a marked suppression is seen) and the mode of phenomic death is necrosis. Some biological implications of the results are discussed. Author-abstract.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Radionuclides, especially the long-lived ¹³⁷Cs (physical half-life 30 years), are accumulated efficiently in the northern, subarctic, lichen-reindeer-man foodchain. Until the Chernobyl accident the fallout nuclides studied originated from *nuclear* weapons tests. After this accident some fresh fallout was deposited in Finnish Lapland. Lichens grow very slowly and collect nutrients very efficiently from air, rain and snow. During winter the basic fodder plants for reindeer are lichens and some winter-green plants, shrubs

and dry leaves. During the bare-ground season, the reindeer eat various grasses, herbs and leaves etc. Lichens constitute 30-50 per cent of the entire vegetable mass consumed by the reindeer in a year. The highest ¹³⁷Cs-concentration 2500 Bq/kg dry weight was found in lichen in the middle of the 1960s. In 1985 the concentration had decreased to about 240 Bq/kg dry weight. After the Chernobyl accident the ¹³⁷Cs-concentration in lichen varied from 200 to 2000 Bq/kg dry weight in Finnish Lapland. In reindeer fodder plant samples collected in the 1980s before the Chernobyl accident the ¹³⁷Cs-concentration varied from 5 to 970 Bq/kg dry weight. The highest ¹³⁷Cs-concentration in reindeer meat, about 2500 Bq/kg fresh weight, was found in 1965 and thereafter decreased to about 300 Bq/kg fresh weight in the winter before the Chernobyl accident. After the accident the mean ¹³⁷Cs-concentration in reindeer meat from the 1986-87 slaughtering period was 720 Bq/kg fresh weight and in 1987-88, 630 Bq/kg fresh weight. Author-abstract.

 JT ZEITSCHRIFT FÜR LEBENSMITTEL-UNTERSUCHUNG UND -FORSCHUNG.
 PT JOURNAL-ARTICLE (ART).
 LG German (GE).
 AB In a field investigation (1983-1985) comprising eight places of the
 most important viticultural regions in the Federal Republic of
 Germany, the contents of the radionuclides tritium (3H), carbon-14
 (14C), strontium-90 (90Sr), and cesium-137 (137Cs) in air, soils,
 leaves of the vine, grapes and wine were measured and site-specific
 transfer factors were calculated. Data concerning soil parameters,
 climatic conditions, cultivation and vinification were collected.
 The tritium content of all samples was 10 Bq/l water of combustion,
 independent of location and year. The specific activity of 14C in
 the atmosphere and in biological material was 0.22 Bq/g carbon,
 independent of site and year. 90Sr contents of soils fluctuated
 between 0.7 and 3.5 Bq/kg dry matter. The mean content of leaves was
 2 Bq/kg fresh material, of grapes 0.035 Bq/kg and of wine 0.008 Bq/l.
 137Cs content of soils fluctuated between 1.3 and 7.9 Bq/kg dry
 matter. The mean content of leaves was 0.098 Bq/kg fresh material,
 of grapes 0.021 Bq/kg and of wine 0.0085 Bq/l. A relation between
 transfer of radionuclides and soil parameters and between the
 contents of grapes and wine was not recognizable. While
 cultivar-specific differences were not observed in grapes, red wines
 contained somewhat more 137Cs than white wines. Transfer factors
 soil grapes were 0.027 for 90Sr and 0.0057 for 137Cs. Site-specific
 influences such as soil parameters, climate, cultivation,
 vinification and differences between years led to a relatively small

fluctuation of values. An influence of the *nuclear* power station Neckarwestheim has not been found in any of the radionuclides.

TI Measurements of electromagnetic emissions from video display terminals at the frequency range from 30 Hz to 1 MHz.
SO Health-Phys. 1989 Jul. 57(1). P 79-88.
JT HEALTH PHYSICS.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Electric (E) and magnetic field (B) strengths or flux densities were measured at distances of 30 and 50 cm from the screen of video displays at a frequency range from 30 Hz to 1 MHz. The measurement system consisted of an optically coupled active dipole for E-fields, a magnetic field meter, a digital oscilloscope, a portable computer for data storage and a laboratory computer for Fourier analysis of the recorded signals. Comparison of measurement results with available broadband exposure standards or proposed standards indicated that magnetic flux density should be measured at both the (ELF) frequency range from 30 Hz to 300 Hz and at the (RF) frequency range from 10 kHz to 500 kHz. Alternatively, time derivative of magnetic flux density may be measured. Nor should the measurement of the electric field strength at the RF range be neglected. These conclusions, however, are valid only in relative terms. In all cases

the exposure is at least one decade below the most stringent exposure limit. The maximum relative exposure 0.077 was obtained by applying the ACGIH standard for magnetic fields at a distance of 30 cm from the screen. The field strengths decrease by a factor varying from 2.5 to 3.5 at a distance of 50 cm, which is a more realistic distance when considering actual working conditions. Author-abstract.

JT HEALTH PHYSICS.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB The accident at the Chernobyl *nuclear* power plant in April 1986 caused very uneven deposition of radionuclides in Finland. The deposited radionuclides were found in relatively high concentrations in fuel peat and especially in peat ash because a thin surface layer of peat-production bogs was extracted as fuel peat soon after the fallout occurred. Concentrations of artificial radionuclides in fuel peat and peat ash were measured at six peat-fired power plants in Finland throughout the heating season 1986-87. Concentrations of ¹³⁷Cs in composite peat samples varied between 30 and 3600 Bq kg⁻¹ dry weight and in ash samples between 600 and 68,000 Bq kg⁻¹. High concentrations in peat ash caused some restrictions to the utilization of peat ash for various purposes. Author-abstract.

AB A quality-control project covering 56 pieces of mammographic equipment was carried out in Finland. The evaluation was based on the determination of contrast, film optical density, resolution, focus size, tube voltage, exposure time, half-value thickness, reproducibility and linearity of exposure, surface and exit dose, and defects at each centre when employing routinely used techniques. Dose and image quality were assessed using three phantoms. The results are compared with those obtained 5 years earlier and by other authors. Although the situation has, in many ways, improved considerably over the last 5 years (for instance, the average whole-breast dose has fallen on average by 84%, 7.37----1.10 mGy), there is still room for further improvement, especially in the optimization of the developing processes. TI Suicidal death of rat chloroleukaemia cells by activation of the long interspersed repetitive DNA element (L1Rn).
SO Cell-Tissue-Kinet. 1988 Jan. 21(1). P 33-43.
JT CELL AND TISSUE KINETICS.
PT JOURNAL-ARTICLE (ART).
LG English (EN).

AB Rat chloroleukaemia cells, maintained in suspension culture in different media, show rapid exponential growth without cell loss. At about half of the maximal population density the long interspersed repetitive DNA element (L1Rn) is suddenly transcriptionally activated without any obvious exogenous reason. Population growth is then inhibited and, within about 24 h after reaching the maximal density, the population undergoes programmed death (apoptosis). Suicidal cell death is caused by sudden incorporation, apparently by retroposition via an RNA intermediate, of about 300,000 copies of the L1Rn element into random locations in the cell genome, thus creating lethal mutations. The preceding growth inhibition is associated with repression, to an undetectable level, of c-Ki-ras expression. Up to the point of massive L1Rn incorporation and cell death, all phenomena are quickly reversible by subculturing; medium change alone is not sufficient. Biological implications of these surprising findings are discussed. Author-abstract.

JT ACTA RADIOLOGICA.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB The radiation dose exposure, and the faults in about 1,700 dental units inspected at dental surgeries by the Finnish Centre for Radiation and *Nuclear* *Safety* in 1981-1985, were analysed. The mean value of skin doses in the bite-wing projection was about 6.2 mGy, the range 0.5 to 151 mGy. The mean energy imparted per bite-wing examination was estimated as 0.68 mJ and that per panoramic examination as 1.2 mJ. That gives a total imparted energy of about

600 J per year for conventional dental examinations and about 420 J per year for panoramic examinations. This gives a total of 0.13 mJ from conventional and 0.089 mJ from panoramic examinations per inhabitant per year. The collective effective dose equivalent was calculated as about 9 manSv for conventional dental examinations and about 6 manSv for panoramic examinations. Twenty per cent of units had some fault which was capable of decreasing radiation *safety.* Forty per cent of units were served reparation orders or other remarks were made in inspection documents. Large doses were usually accounted for by incorrect film processing and malfunction of the exposure timer. Author-abstract.

AB The image quality in mammography was evaluated for all the 56 equipment-image receptor combinations used in Finland with two phantoms containing test objects of three types and different sizes. We obtained 2-8 fold variations for the smallest sizes of the three objects (specks, fibres and masses) visible in the X-ray images and 3.0-3.7 fold variations for an "image score". The smallest speck, fibre and mass sizes visible in the radiographs were 0.24, 0.75 and 0.5 mm, respectively. An unacceptable image quality was obtained in 36% of the studied cases. A recommendation is presented.

+50Y*p0X{oh'-puhr-ohn}*p+50Y*p0X *p+50Y*p0XIn genetics, the term operon is used

to specify the model of*p+50Y*p0Xgene regulation proposed by French scientists

Francois JACOB*p+50Y*p0Xand Jacques MONOD in 1961. Two types of gene are

involved:*p+50Y*p0Xcontrol and structural. The control genes of each

operon*p+50Y*p0Xinclude a regulator, promoter, and operator gene, whereas

the*p+50Y*p0Xstructural genes determine the amino acid sequences of

various*p+51Y*p0Xproteins. A great deal of experimental evidence exists for the

*p+50Y*p0Xoperon model, which describes very well the

regulatory*p+50Y*p0Xmechanism of enzyme production in prokaryotes (see

PROKARYOTE), *p+50Y*p0Xsuch as bacteria and blue-green algae. Based on the

conditions *p+50Y*p0Xdetermining their production, two types of enzymes

are*p+50Y*p0Xinvolved: inducible and repressible.*p+50Y*p0XInducible

Enzymes*p+50Y*p0X *p+50Y*p0XInducible enzymes are involved in splitting complex

molecules*p+50Y*p0X(substrates), a process known as catabolism, that

provides*p+51Y*p0Xenergy or simple materials for the synthesis of

other*p+50Y*p0Xcompounds. An inducible enzyme is produced only when

the*p+50Y*p0Xspecific substrate on which it acts is present. For

example,*p+50Y*p0Xthe enzyme beta-galactosidase, which breaks down lactose

into*p+50Y*p0Xgalactose and glucose, is formed only when lactose is

present;*p+50Y*p0Xin the absence of lactose, the synthesis of this

enzyme*p+50Y*p0Xvirtually stops.*p+50Y*p0X *p+50Y*p0XThe inducible enzyme system

involves two types of genes: a*p+50Y*p0Xregulator gene, which determines whether

the enzyme will be*p+51Y*p0Xproduced; and one or more structural genes, which

specify the*p+50Y*p0Xamino acid sequence of the enzyme being produced.

Two*p+50Y*p0Xattachment loci on the structural genes control the movement of *p

+50Y*p0Xribonucleic acid (RNA)-polymerase molecules onto the genes.*p+50Y*p0X *p

+50Y*p0XIn the absence of the substrate the regulator gene (i) produces a *p

+50Y*p0Xrepressor substance (R) that attaches to the operator locus*p+50Y*p0Xand

prevents the RNA-polymerase molecules from attaching to the *p+50Y*p0Xstructural

genes. When the substrate, known as the inducer*p+50Y*p0X(I), is present, the

repressor substance combines with the*p+51Y*p0Xinducer to form a molecule that is

unable to attach to the*p+50Y*p0Xoperator locus. RNA-polymerase molecules can

then transcribe*p+50Y*p0Xinformation, and subsequent translation produces the

inducible*p+50Y*p0Xenzyme.*p+50Y*p0XAnother controlling element in this system,

called the promoter *p+50Y*p0Xlocus, is the site of attachment of the

RNA-polymerase prior to *p+50Y*p0Xtranscription. The speed with which

ACADEMIC AMERICAN ENCYCLOPEDIA*p+50Y*p0X

*p+51Y*p0XOPERON*p+50Y*p0X *p+50Y*p0Xattach to the promoter locus determines the

rate of production*p+50Y*p0Xof messenger RNA (mRNA) and subsequently of

enzymes.*p+50Y*p0X *p+50Y*p0XRepressible Enzymes*p+50Y*p0X *p+50Y*p0XThese

enzymes are involved in the cell's synthetic process and*p+50Y*p0Xare produced

only when the protein that they help metabolize is *p+50Y*p0Xlacking. As an

example, the enzymes involved in synthesizing the amino acid histidine are produced only when the amount of free histidine in the cell is drastically reduced. In the presence of free histidine enzyme production stops. The operon model of gene regulation for repressible enzymes has one important difference from the inducible enzyme system. In the repressible system the repressor substance (R), produced by the regulator gene (i), cannot attach to the operator locus (O+) if the end product, known as corepressor (CR), is absent. Therefore, if the corepressor is absent, transcription and subsequent translation occur. Whenever the end product is present it combines with the repressor substance to form a molecule that can attach to the operator locus and terminate transcription. The functioning of the promoter locus is the same for both inducible and repressible enzyme synthesis. Gene Regulation in Eukaryotes Gene regulation in eukaryotes (see EUKARYOTE)--such as protozoa, molds, and all higher organisms--does not appear to allow the simple operon model, and no other general pattern of gene regulation has been found. In many higher organisms hormones determine development and function; here too, however, no consistency of action is observed. For example, steroid hormones enter the cell, pass into the nucleus, and produce their effects by turning on the transcription of specific genes, whereas the peptide hormones remain on the surface of the cells and produce their effects through the activation of preformed genes. Human hemoglobin provides a very complicated instance of gene regulation. Each hemoglobin molecule consists of two pairs of polypeptide chains. In early embryonic development the two types of chains are zeta and epsilon, but at about eight weeks after conception their production is terminated and two other types, called alpha and gamma, are produced. At birth, gamma production is replaced by production of so-called beta chains. Copyright (c) 1994 Grolier Electronic Publishing, Inc. All rights reserved.▲

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR ENERGY

Nuclear energy refers to the energy consumed or produced in modifying the composition of the atomic nucleus. The force that arms the ATOMIC BOMB and HYDROGEN BOMB and other NUCLEAR WEAPONS, nuclear energy also powers electricity-generating plants in countries throughout the world. It is seen by many as the source of inexpensive, clean power; but, because of the hazardous radiation emitted in producing that power and the RADIOACTIVITY of the materials used, others feel that it may not be a viable energy alternative to the use of fossil fuels or solar energy.

This article discusses the science involved in the release of nuclear energy, and the use of that science by the industries that produce electric power. The process by which nuclear-based electricity is produced is examined in NUCLEAR REACTOR, as are some of the safety issues involved. The unwanted byproducts of nuclear energy production are described in NUCLEAR WASTE.

BASIC SCIENTIFIC DEFINITIONS

The processes that change the state or composition of matter are inevitably accompanied by the consumption or production of energy. Common processes such as combustion produce energy by the chemical rearrangement of atoms or molecules. For example, the combustion of methane (natural gas) is represented by the chemical reaction

For this example the energy release is 8 electron volts (ev). The electron volt is a unit of energy used by nuclear physicists and represents the gain in kinetic energy when an electron is accelerated through a potential drop of one volt.

The most well-known nuclear reaction is fission, in which a heavy nucleus combines with a neutron and separates into two other, lighter nuclei. A typical fission reaction involving uranium-235 is

where the energy release is about 200 million electron volts (meV), a factor of 25 million greater than the combustion

reaction of methane (see FISSION, NUCLEAR).

06/25/93

11:29 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR ENERGY

Another important nuclear reaction is fusion, in which two light elements combine to form a heavier atom. An important fusion reaction is

where the energy release of the reaction is 18 million eV (see FUSION, NUCLEAR).

Nuclear power plants harness the enormous energy releases from nuclear reactions for large-scale energy production. In a modern coal plant the combustion of one pound of coal produces about 1 kilowatt hour (kWh) of electric energy. The fissioning of one pound of uranium in a modern nuclear power plant produces about 3 million kWh of electric energy. It is the incredible energy density (energy per unit mass) that makes nuclear energy sources of such interest.

At present, only the fission process is used in the commercial production of energy, usually to make electricity, but also occasionally to produce steam for district heating or industrial applications. Fusion research has not yet produced a feasible power production technology (see FUSION ENERGY).

DEVELOPMENT OF FISSION TECHNOLOGY

The discovery of the fission process occurred in the late 1930s, the result of a long sequence of nuclear physics studies. The German scientists Otto HAHN and Fritz Strassmann reported on an experiment involving neutron irradiation of uranium in early 1939. Subsequently, Otto Frisch and Lise MEITNER interpreted the experiment as the fissioning of uranium into lighter elements. The possibility of a self-sustaining chain reaction was apparent, and provided added impetus for accelerated research.

Secret government research into the military applications of nuclear fission began with World War II (see MANHATTAN PROJECT). The development of a weapon required that a

self-sustaining fission reaction could be created and, further, that an adequate amount of fissionable material could be produced for use in a weapon. On December 2, 1942, at the University of Chicago, a team under the direction of Enrico FERMI successfully brought the world's first reactor to a

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR ENERGY

self-sustaining, or "critical," state. The reactor was fueled with natural uranium imbedded in graphite blocks. The fissioning occurred in the isotope of uranium, U-235.

Natural uranium contains only 0.7% of U-235, while the remaining 99.3% of the uranium is U-238, which does not fission except with very high energy neutrons not available from the fission process. In making a bomb, it was necessary to provide much higher concentrations of U-235, or "enriched uranium," and ultimately, a form of gaseous diffusion was used to separate U-235 from U-238. A significant part of the Manhattan Project was devoted to developing a processing technology to separate U-235 from U-238. Ultimately, the solution was found in a form of gaseous diffusion that was used to separate the two materials. An alternative pathway to obtaining weapons material is to use a different fissionable nucleus. Such a material is the synthetic isotope of plutonium, Pu-239, formed when U-238 reacts with neutrons to produce U-239. U-239 is radioactive and decays in two steps to produce Pu-239. In order to produce plutonium, however, a large reactor is needed to irradiate the U-238.

Once Fermi had demonstrated that a critical reactor was feasible, a major effort was undertaken to build reactors to produce plutonium. The first such reactor, in Oak Ridge, Tennessee, was followed by large-scale plants in Hanford, Washington. The technology required to design, build, and operate these plants was developed in a remarkably short time--less than three years--and the knowledge created was the driving force behind the realization of the potential of nuclear energy in the commercial world.

The concept of an energy source that promised extended naval voyages without refueling was obviously worth investigation. Under the direction of Hyman RICKOVER, a naval reactor program began in the late 1940s and the first nuclear submarine, the

NAUTILUS, was launched in 1954. An outstanding success, the Nautilus proved the merits of nuclear propulsion for naval vessels. Its reactor was the prototype for the first commercial nuclear power plant, built in Shippingport, Pennsylvania, in 1957.

The decision to declassify much nuclear-related information in order to foster peaceful applications was made by President Dwight D. Eisenhower and announced in his "Atoms for Peace"

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR ENERGY

speech at the United Nations in December 1953. Other nations joined in the search for peaceful uses for the atom, and the first international conference on nuclear energy was held in Geneva in 1955. In the United States the Atomic Energy Commission--founded in 1946 to oversee civilian uses of nuclear power--sponsored research on a host of reactor concepts that led to the birth of the civilian industry. Britain entered into the production of nuclear-fueled electricity in 1956. The first Soviet nuclear power plant came on line in 1954, and the French began construction of their first commercial plants in 1957. By the early 1960s nuclear power had been established as a viable commercial energy source.

NUCLEAR ENERGY TODAY

In the 50 years since the discovery of fission, nuclear power has become a major source of the world's electric energy. At the end of 1989 there were 416 nuclear plants operating worldwide, generating about 17% of the world's electricity, with another 130 in the design or construction stages. Nuclear plants operate in 27 nations, and 5 additional nations have them under construction.

The nuclear energy program in the United States is the world's largest: 108 operating plants (1989) have a capacity of about 100,000 MW and provide nearly 20% of U.S. power generation. Nuclear power is now the second largest source of U.S. electricity, exceeded only by coal, which provides about 55% of the country's electricity. Other contributors to electric generation include natural gas (9%), oil (6%), and hydropower (9%). The nuclear fraction is expected to reach about 25% during the 1990s.

In general, nuclear plants are more complex and costly to build than plants using fossil fuels--although the cost of fuel for nuclear plants is significantly lower. On balance, the fuel cost difference is such that nuclear electricity is cheaper than fossil electricity for most nations. For the industrialized countries of Europe and Asia the difference in cost may be as large as a factor of two.

The French Nuclear Program

The French nuclear program was begun in the 1940s in order to create a nuclear weapons capability. As in the U.S. program,

Copyright (c) 1993 Grolier Electronic Publishing, Inc. All rights reserved.
▲PRODIGY(R) interactive personal service 06/25/93 11:29 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR ENERGY

the first French reactors were built for plutonium production. The first French commercial units, which used air as a coolant, were in operation by 1957. Their operation was a technical, but not an economic, success. As a result, in 1970, the French adopted the U.S. light-water technology. Subsequently, the French have built 54 domestic reactors with 9 more under construction. The French standardized their designs to improve the efficiency of construction and operation. They have also built units for Belgium, South Africa, South Korea, and China.

The Japanese Nuclear Program

The Japanese also have a vigorous and successful nuclear program. Lacking any significant indigenous energy resources, in 1955 the Japanese government selected nuclear power as its major electric-supply technology. The program has carefully nurtured the internal capability to manufacture equipment and construct nuclear plants, to operate a high-quality power system, and to provide complete technology for the entire fuel cycle. The utilities in Japan have become leaders in plant operation; and by 2020 the nuclear-fueled portion of Japan's electric supply is expected to exceed 50 percent. In the future the Japanese plan to exploit the potential of BREEDER REACTORS, which convert nonfissionable U-238 into fissionable plutonium-239. A successful breeder reactor program could eliminate Japan's need to import any fuels for the production of electricity. To date, however, the cost of electricity from breeders exceeds the cost from conventional light-water

reactors. The Japanese long-range policy assumes that uranium fuel will ultimately become scarce, making the breeder technology economical.

The Slowdown in Other National Programs

Nuclear power programs in most other countries have come to a virtual standstill. (In the United States there has not been an order for a new plant since the mid-1970s.). A major cause has been the move toward increased efficiency in the consumption of oil, and a drop in energy demand. Equally significant have been concerns about the safety of nuclear reactors and in increasing awareness of the problems created by nuclear waste.

Public opinion remained largely favorable toward nuclear energy until the Three Mile Island (TMI) reactor accident in the

06/25/93

11:29 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR ENERGY

spring of 1979. The accident began with the failure of some of the plant hardware. By itself, the failure would not have caused serious damage to the reactor, but a series of mistakes in interpreting the condition of the reactor led to more mistakes, which removed reactor coolant and caused a sizable portion of the fuel to melt. Although there was extensive damage to the reactor, the containment system functioned, preventing the release of much radioactivity to the environment. Nevertheless, there was widespread apprehension for several days among the nearby population. The events at TMI captured the attention of the world, dominated the media for days, and caused a historic shift in attitudes toward nuclear power.

The accident also had serious impacts on the licensing of new plants. Regulations were drastically modified to prevent a recurrence of the events of TMI. The modifications complicated the construction of new plants as well as the operation of existing plants. Construction times expanded from about 6 years to more than 12 years, and plant costs accelerated rapidly because of the new requirements.

Another factor contributing to the stagnation of new construction was the intervention by anti-nuclear groups in

licensing proceedings for new plants. Such intervention has proven to be time consuming and costly to the industry, particularly for those plants in the late stages of construction, when interest costs mount on the billions that have been borrowed. The Shoreham (New York) and Seabrook (New Hampshire) plants are notable examples of cost overruns, caused in part by completion delays.

Although few other countries permit the extent of public intervention in licensing hearings that is allowed in the United States, all the major nuclear nations impose strict regulations on their nuclear energy plants. Nevertheless, studies indicate that, for the most part, the U.S. industry performs far less efficiently than do those in Switzerland, Germany, France, and Japan. A key factor in their superior performance may be the cooperation that exists between the industries and their suppliers and regulators--a cooperation that, until recently, was not apparent in the United States.

In its early years, nuclear power was cost competitive with coal. Some of the cheapest sources of electricity in the

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR ENERGY

United States today are nuclear plants built in the period before TMI. The current environment, however, has made nuclear power an uneconomical choice for U.S. utilities.

Chernobyl

The accident in April 1986 at the CHERNOBYL plant in the USSR was as devastating as a nuclear accident can be. A very large amount of radioactive material--between 30% and 50% of the total material in the reactor--was released. Radioactive fallout from the event spread, forcing the long-term evacuation of over 100,000 local people and causing the pollution of foods in large portions of Europe.

The Chernobyl reactor design uses water as a coolant and graphite as the moderator. This type of reactor is known to be hazardous and is used only in the USSR. (Such a design would not be licensed in the Western nations.) Nevertheless, the accident has profoundly influenced worldwide public acceptance of nuclear power. It is too early to know whether or not the

Chernobyl accident has permanently crippled the future of nuclear power in industrialized countries.

NUCLEAR MEDICINE

The use of isotopic or radioactive tracers to diagnose or treat disease is the branch of RADIOLOGY known as nuclear medicine. These radiographic techniques are valuable aids to and sometimes superior to X rays. Because of the very small amounts of radioactive substance utilized, patient exposure to radiation is usually minimal.

Both diagnostic studies and radiotherapeutic treatments may be performed using radioactive materials in a variety of pharmaceutical forms. Tiny amounts of compounds "tagged" with radioactive isotopes are introduced into the body either orally or by injection into a vein. These substances travel through the bloodstream to the specific organ or type of tissue being evaluated. The radiation that is released by the isotopes is detected by devices called scintillation cameras. Computers convert the data from these cameras to images that allow

visualization of parts of organs that are not usually seen by normal X rays. By tracking how and where the radioactive compounds go, the nuclear-medicine physician is able to gain information about biological processes, such as in a heart scan, which determines if any areas of the heart are not receiving sufficient amounts of blood. Also, a therapeutic dose of radiation can be delivered to a specific organ for treatment, for example, radioactive iodine for thyroid disorders.

Some examinations involve collecting specimens of blood, stool, or urine and measuring the radioactivity in them. In a radioimmunoassay a radioactive substance is placed in a blood sample to detect minute amounts of specific substances, such as antigens or hormones. WILLIAM M. GREEN, M.D.

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR PHYSICS

Nuclear physics is the study of the properties of the atomic nucleus (see ATOM). The nucleus, centrally located in the atom and surrounded by electrons, is composed of NEUTRONS and PROTONS, which current theory holds are themselves composed of QUARKS (see FUNDAMENTAL PARTICLES). Collectively called nucleons, they are bound tightly by the strong nuclear force (see FUNDAMENTAL INTERACTIONS). The experimental tools of nuclear physics are particle ACCELERATORS and DETECTORS. Applications of nuclear physics include NUCLEAR ENERGY (see also FISSION, NUCLEAR; FUSION, NUCLEAR), NUCLEAR WEAPONS, and the use of radioisotopes in industry and medicine (see NUCLEAR MEDICINE; RADIOLOGY).

Nuclear Properties

A specific kind of nucleus is designated by writing A over Z X. Here X is the chemical symbol of the element, Z is the ATOMIC NUMBER (the number of protons in the nucleus), and A is the MASS NUMBER (the combined number of protons and neutrons). Nuclei with the same number of protons but different numbers of neutrons are called ISOTOPES of one another. Nuclei containing certain numbers of protons or neutrons are particularly stable. The values of these numbers, called magic numbers, are 2, 8, 20, 28, 50, 82, and 126.

The properties of a nucleus include MASS, charge, size, shape, spin, and MAGNETIC MOMENT. The positive charge on the proton is of exactly the same magnitude as the negative charge on the electron. The mass of a nucleus is approximately the sum of the free masses of its particles. The attractive nuclear force, however, causes a small decrease in mass, called the MASS DEFECT (see BINDING ENERGY). The size of a nucleus is determined by bombarding it with some other particle and measuring its CROSS-SECTION by the probability of collision. The radius of a nucleus has been determined to be about $1.3 \times 10^{-13} A^{1/3}$ cm, where A is the mass number.

Neutrons and protons have spins, and their motions within the nucleus may contribute orbital angular momentum. The orbital angular momenta and spins of the nucleons combine according to the rules of QUANTUM MECHANICS to give the total spin of the nucleus. The rotation of the electrical charge of the nucleus creates a magnetic field. The field's strength is the magnetic moment of the nucleus. A nucleus is usually approximately spherical in shape, but some are ellipsoidal.

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR PHYSICS

Nuclear Structure

The motions of the particles within a nucleus determine its properties. They cannot be calculated exactly, so physicists have invented simplified models from which properties can be predicted. One model assumes that the nucleus is similar to a charged liquid drop. The mass of a given isotope is primarily

the sum of the free masses of its nucleons. Corrections are calculated for the nuclear binding, the surface tension of the drop, and the electrostatic repulsion of the protons in the nucleus, taking note also of the excess of neutrons over protons, and whether the nucleon number is odd or even. The resulting formula can be adjusted to fit closely all the measured masses of the known isotopes.

Some nucleus properties are explained by the shell model, which assumes that each nucleon moves in an average field created by all the other nucleons. Its permitted orbits, or energy levels, are then calculated by quantum mechanics. Corrections are made for the spin-orbit force, which depends on whether a nucleon's spin is parallel or opposite to its orbital angular momentum. The shell model permits the calculation of the energies of many excited levels of nuclei and the way in which the spins and angular momenta of the individual nucleons combine to give the net spin of the nucleus.

Energy levels of some nuclei exhibit patterns of regularity. In the collective model of the nucleus, these properties are assumed to be determined by the motion of the nucleus as a whole. Finally, the unified model of the nucleus combines the effects of the collective and shell models to provide more comprehensive agreement with experimental observation.

Nuclear Reactions

When nuclei collide, the interaction may result in products different from the initial nuclei. The total momentum and angular momentum, however, must remain the same after the reaction. The total number of nucleons also remains unchanged, as does the total electric charge (see CONSERVATION, LAWS OF). A small but significant amount of mass (up to 1%) may be transformed into energy, or vice versa, during a reaction, but the total mass-energy is conserved as well. The conversion factor for mass into energy is the square of the velocity of light, as in $E = mc^2$, where c is the velocity--an extremely

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR PHYSICS

large number (see RELATIVITY).

In Niels BOHR's model of nuclear reactions, a bombarding particle penetrates a nucleus to form an intermediate compound

nucleus that lasts only long enough for the energy and momentum of the incident particle to be shared among all the nucleons. The system decays by emission of neutrons, protons, and other particles, referred to as evaporated particles. If a given compound nucleus is formed by different bombarding particles and target nuclei but at the same total energy, the products of the reaction remain the same.

In the direct interaction model, the incident particle is assumed to pass through the target nucleus relatively freely and to interact directly with only one or a small number of nucleons. The struck particle is ejected from the nucleus, and the incident particle may also reemerge. At high bombarding energies the incident particle may leave residual energy for compound nucleus evaporation products or may eject sizable fragments from the target. These latter are called spallation reactions, meaning the fragmentation of the nucleus.

Nuclear Forces

The strong nuclear force, carried only by the neutron and proton, is the strongest force known in nature. Its range is about one fermi, a distance of 10^{-13} cm. It weakens rapidly with distance and has little effect more than a few fermis from a nucleus. On the other hand, at distances smaller than about 0.4 fermi it becomes strongly repulsive. This region, called the hard core of the strong nuclear force, is responsible for the constant density of nuclear matter.

The weak nuclear force is involved in nuclear decay processes and in interactions involving the fundamental particles called NEUTRINOS. No complete theory combining the fundamental forces has yet been developed, but current theoretical work in particle physics is attempting to devise GRAND UNIFICATION theories that will do so.

Nature of Matter (1981); Patel, S. B., Nuclear Physics
(1988); Romer, Alfred, The Restless Atom (1982).

NUCLEAR REACTOR

A nuclear reactor is a device in which a controlled nuclear fission chain reaction takes place. The fission reaction is initiated by the absorption of a neutron in a heavy nucleus such as uranium-235 (U-235). The process produces additional neutrons that can be used to induce further fissions, thereby propagating the chain reaction. When the reactor materials are appropriately adjusted, it is possible for the chain reaction to be self-sustaining. Such a reactor is called "critical." If there are insufficient neutrons being produced to sustain the process, then the reactor is "subcritical." Conversely, if too many neutrons are being produced, the reaction rate increases with time and the reactor is called "supercritical" (see NUCLEAR ENERGY).

Nuclear reactors are most commonly used to produce electric energy, although they are occasionally used as sources of thermal energy for heating. They are also designed as sources of neutrons used in research or for the transmutation of elements. Reactors designed to produce materials for nuclear weapons by transmutation are called production reactors.

Numerous devices use nuclear processes other than fission as their energy source, although these devices are not called nuclear reactors. For instance, power supplies on spacecraft use the energy from radioactive decay, and hence are called "radioisotope power supplies." Similarly, devices based on the fusion process are called "thermonuclear" or "fusion" reactors.

FISSION CREATION AND CONTROL

The energy released in the fission process takes several forms. Almost 85% of the energy produced is kinetic energy of the fission fragments. About 3% appears as the kinetic energy of the neutrons released, and another 3% as gamma-ray energy. All of the energy from these sources is released immediately and can be recovered from the reactor. A small amount of energy, about 5%, is carried away by neutrinos, which do not interact readily with matter. This fraction of the energy is lost from the reactor. Finally, about 6% of the total energy is obtained from the decay of radioactive fission fragments. This delayed source of energy plays a significant role in the safety of nuclear reactors. Long after the fission process has been shut off, the inventory of accumulated fission products will continue to produce energy. It is essential to cool the reactor to prevent overheating.

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR REACTOR

LIGHT WATER REACTORS

The typical U.S. power reactor is termed a light-water reactor (LWR) because it uses water in the form of H_2O as a moderator and coolant. Another type of power reactor uses a type of water in which the hydrogen has been replaced by deuterium -- D_2O --as a moderator; it is called a heavy-water reactor.

The design characteristics stem from a set of physical, engineering, and economic constraints. The physical aspects of the design seek to provide the nuclear fuel and other constituents so that a safe and controllable reactor can operate at the desired power level for an extended period of time. The engineering aspects of the design seek to convert the fission energy into a useful form of heat, usually high-pressure steam, to drive a turbine which is connected to an electric generator. The economic aspects of the design seek to optimize the physical and engineering design so as to minimize the cost of energy from the plant. Typically, it is possible to provide a range of options in design that are satisfactory from the technical view. The final choices rest with the relative economics of the various options.

Reactor physicists are primarily concerned with finding means to promote the fission reaction so as to keep the reactor critical. This implies a careful balance between the neutron production rate (the fission rate) and the neutron loss rate. Neutrons are lost via two mechanisms: they may be captured by nuclei that do not fission, or they may simply migrate out of the region containing nuclear fuel.

The core of a reactor is the region that contains the nuclear fuel. Neutrons from the fission process are born with relatively high energy. However, the probability of a neutron causing a fission in the fuel nuclei is much larger for low energy neutrons than for high energy neutrons. In order to slow neutrons down, it is common to surround the fuel with a moderator. Neutrons can interact with nuclei much like collisions between hard spheres. The neutron will lose energy most efficiently, i.e., in fewest collisions, if the moderator nuclei are close to the mass of the neutron. Thus, moderators are made from light materials such as hydrogen in water,

deuterium in heavy water, or carbon in graphite. The physical arrangement of the fuel and moderator is a major element of reactor physics.

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR REACTOR

The LWR uses H_2O as the moderator and uranium dioxide, UO_2 , as the fuel. The fissionable isotope of uranium is U-235, which makes up only 0.7% of natural uranium. It is not possible to design an LWR that uses natural uranium. In order to increase neutron production, the U-235 concentration in the fuel is increased. Such fuel is called "enriched."

Fuel for an LWR has a relatively simple structure. Uranium is pressed into small cylindrical pellets that are stacked in zirconium alloy tubes--the "cladding"--about 3.05 m (10 ft) in length. The tubes are arranged in a "fuel assembly," a square array containing about 17 tubes on a side. A modern pressurized water reactor has about 200 fuel assemblies in its core.

Reactor control is achieved by carefully balancing the neutron production rate by fission with the neutron loss rate. The common process for obtaining control is to adjust the amount of neutron absorber in the core. Control materials are placed in rods with the same dimensions as fuel rods and the set of control rods are inserted in the middle of a fuel assembly. The control rods are attached to a drive mechanism that moves the control rods into or out of the core region. A typical set of control rods contains materials that are highly absorbent to neutrons such as silver, indium, and cadmium. The control rods are inserted into the core when reactor shutdown is desired. The rods are also inserted automatically in the event that unexpected conditions are detected.

The core, including fuel assemblies, control rods, and moderator, is a very large system on the order of 3.65 m (12 ft) diameter and 3.65 m high. The entire assemblage fits into a 12-m-high (40 ft), thick-walled steel pressure vessel, designed to withstand very high pressures, up to 2,500 psi. For LWRs, water is both the moderator and the coolant, that is, the agent used to remove fission energy from the core and transfer it to the electric generating segment of the system.

In the pressurized water reactor (PWR)--a type of LWR--water is heated to a high temperature without boiling, by keeping the system under very high pressure. Water is piped into the pressure vessel and flows down the vessel sides to a region below the core. It then flows up through the core, gaining heat while keeping the core cooled. The heated water flows

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR REACTOR

through pipes to a steam generator. The sets of pipes and associate pumps are called "loops." Typically, a large PWR has 4 loops.

In the primary loop, hot water from the core flows through a steam generator, where it exchanges heat with water in a second loop. Second-loop water, under lower pressure, will boil and produce steam, which in turn is fed to turbines to drive a generator. The primary water returning from the steam generator is pumped through the reactor core again. In passing through the core region, the primary water is subject to neutron irradiation, and some of its constituents will become radioactive. Further, small amounts of activity are scrubbed off the cladding material and other internal parts of the reactor. As a result, primary water is contaminated with radioactivity. It is very important that this water be kept apart from the plant operating staff. The shielding of the entire vessel and its internals, the coolant loops, and steam generator is accomplished by keeping all of these components inside a very large concrete shell called the containment building. The large spheres of containment buildings are characteristic features of nuclear power plants. The steam from the secondary side of the steam generator is not radioactive; it flows through the containment walls to an auxiliary building that houses the turbine and generator. The turbine, generator, condenser, pumping equipment, and transformers make up the balance of the plant, and are like those of a conventional energy plant.

OTHER REACTOR TYPES

The pressurized water reactor is the most common type of nuclear reactor used for the generation of electric energy. Over one half of all nuclear power reactors in the world are

PWRs. The second most common reactor is also moderated and cooled with light water. This is the boiling water reactor (BWR), in which the coolant is permitted to boil within the reactor core. The steam emerging from the core is sent directly to a turbine rather than through a steam generator. The BWR has somewhat less equipment that must be held within the containment building and hence they are slightly smaller than PWR containments. The steam that enters into a BWR turbine is radioactive, however, and slightly contaminates the turbine. There are other small differences in detail between the two types of LWRs, but the major components such as the

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR REACTOR

vessel, fuel, control rods, coolant loops, etc., are quite similar in function. The characteristics of the two types of plants have so much in common that several utilities own plants of both types.

Reactors that use various gas coolants, rather than liquids, are collectively called gas-cooled reactors. The first plants of this type were built in Great Britain and France. The commercial versions used CO_2 as a coolant and graphite for moderation. The designs are significantly different from those of LWRs. The fuel is usually uranium, but it is implaced in steel tubes that are in turn imbedded in graphite blocks. There are channels through the graphite for the coolant gases to pass. Typically the gaseous coolant can be heated to a higher temperature in a graphite reactor than one containing structural metals such as steel or zirconium. The heat is again transferred through a steam generator to produce steam to drive a turbine. Because the coolant is at a high temperature the quality of steam produced in the steam generator is very high. Overall, gas cooled reactors tend to have a higher thermodynamic efficiency than LWRs. In spite of the thermodynamic advantages of the gas reactors there were other problems, including economic ones, that led to the economic demise of these plants. One major problem was the corrosion the hot gases caused in various surfaces of the reactor and steam generator. A second factor was the cost of constructing such systems. They tended to be very large in volume, requiring a great deal of material and high labor costs. In the early 1970s the French shifted their emphasis to the LWR technology. Great Britain made a similar decision in the

mid-1980s.

A different type of gas-cooled reactor has been under development in Germany and the United States and is called the high temperature gas-cooled reactor, or HTGR. The significant change from earlier gas reactors is the adoption of helium as the coolant gas. Helium is chemically inert, and as a result causes little corrosion. The fuel has the uranium imbedded in graphite rather than steel, thus the system can operate at very high temperatures, which promotes thermodynamic efficiency. A few HTGRs have been built to demonstrate the technology. The economics of large plants has not been demonstrated.

There is a move toward building small HTGRs, called modular HTGR or MHTGR. It has been suggested that a small plant can be

Copyright (c) 1993 Grolier Electronic Publishing, Inc. All rights reserved.
▲PRODIGY(R) interactive personal service 06/25/93 11:33 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR REACTOR

manufactured in a fabrication plant rather than in the field. Simplified installation of such systems should reduce costs. Further, if the module is small enough there will be important safety advantages to the system. Graphite has a very high heat capacity and melts at extremely high temperatures. If the decay heat stored in a core is sufficiently small, it is possible for an HTGR to withstand any accident that prevents coolant from reaching the core. Such a reactor may be genuinely "walkaway safe," i.e., no human intervention would be required to prevent an accident that could release radioactivity. A final argument made for the modular reactor is that the total plant size can be increased in increments as the power demand increases. Thus, the financial commitments can be kept small if the electric demand stops growing. The few HTGRs built to date are not sufficient to demonstrate the economic or safety advantages anticipated for the MHTGR.

All the reactors mentioned above are known as thermal reactors because the moderation slows the neutrons down to reach thermal equilibrium with the moderator. An entirely separate class of reactors are the "fast" reactors, in which there is no effort to moderate neutron energy.

The chance of a fast neutron causing a fission is much lower than that of a thermal neutron. However, if fast neutrons do cause a fission, more neutrons emerge, and in a carefully

designed system, the excess number of neutrons can be greater than one for each fission. The excess neutrons can be used to transmute nonfissionable species into fissionable species. The most common example is the transmutation of uranium 238 into plutonium 239. Under appropriate conditions it is possible to produce more fissionable material than is consumed in operating the reactor. Thus, it is possible to breed fuel at a faster rate than it is being consumed. Such reactors are called "breeders", and they have been built and demonstrated in the United States, Great Britain, France, Germany, the Soviet Union, and Japan. The largest such plant is a 1200 MW commercial plant in France called "Superphoenix" (see BREEDER REACTOR).

The breeders demonstrated to date have used liquid sodium as a coolant. The plants are called liquid-metal cooled fast breeder reactors, or LMFBRs. The core is made of uranium and plutonium fuel rods, and is surrounded by arrays of rods containing U-238 to be converted into plutonium. This region

▲PRODIGY(R) interactive personal service 06/25/93 11:33 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR REACTOR

of the reactor is termed the "blanket." Liquid sodium is relatively heavy and does not moderate neutrons very much. Further, sodium is an excellent heat-transfer medium. Results thus far show little corrosion caused by the coolant in operating components such as piping, pumps, or valves.

In spite of their advantages LMFBRs have not been economically successful. Part of the reason is that the manufacturing, processing, and handling of plutonium-bearing materials is very costly. Further, the systems tend to be large and their construction requires high material and labor costs. The design is very interesting for the future should uranium ultimately become scarce. In addition, some recent safety experiments have shown these plants to have significant safety features that may make them easy to license and operate.

NUCLEAR SAFETY

As the reactor operates, a large inventory of radioactive isotopes accumulates and represents a unique hazard. Any accident releasing a sizeable portion of these materials would be very serious--as demonstrated by the CHERNOBYL accident. A

fundamental objective of nuclear reactor design is to prevent accidents that could allow the escape of RADIOACTIVITY. In order for fission products to reach the environment several barriers must be overcome. For an LWR, the first barrier is the fuel cladding that contains the fuel as well as the fission fragments. The cladding material is a high-strength alloy of zirconium capable of withstanding high pressures and high temperatures, well beyond normal reactor conditions. The second barrier is the pressure vessel, which is exceedingly strong, but which does have numerous penetrations for the cooling water to enter and exit the vessel. The third barrier is the containment building, which is a large, reinforced concrete building designed to withstand substantial pressure.

In order for any barrier to be breached, the system must first become overheated. There are two possible ways for this to occur. The first is for the fission rate to grow too rapidly for the coolant to remove all of the energy being created. The second is for the coolant system to fail and lose the ability to cool the fuel. Excessive fission energy production is monitored by numerous sensors throughout the core region; if they detect a rapid rate of growth in the fission process, the control rods are automatically lowered into the core to absorb

▲PRODIGY(R) interactive personal service 06/25/93 11:33 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR REACTOR

the fission products. The reactor shuts down.

There is another important design element that protects against possible nuclear runaways. The heating up of a local region of the reactor would cause the nearby cooling water to boil, thereby reducing the water density through the creation of bubbles, or voids. It is a safety requirement of U.S. reactors that creation of coolant voids must, by itself, reduce the fission rate. The amount of water that surrounds a fuel rod is carefully adjusted so that a void reduces neutron moderation and hence reduces the fission rate. This property is not required in the Soviet Union and is the fundamental reason for the disastrous Chernobyl accident. The basic design of LWRs makes them safe against nuclear runaways. It is not physically possible for a light-water reactor to undergo a rapid power excursion, thus an LWR cannot explode like an atom bomb.

The greatest threat to reactor safety is the loss of coolant accident, or LOCA. The fission process itself ceases if a reactor loses its cooling water because the reactor goes subcritical. However, the fuel continues to heat up due to the stored thermal energy as well as from the decay heat of radioactive fission products. Without any coolant the cladding heats up and ultimately melts. Safety systems have been designed and installed in plants to prevent the clad from overheating by providing emergency cooling water. Such systems are collectively known as emergency core cooling systems, or ECCs. All such systems have multiply redundant pathways for introducing water into the vessel under high-pressure or low-pressure conditions. The state of the system will depend upon the exact cause of the loss of coolant. In the event that one of the large coolant pipes ruptures, the system would depressurize rapidly and emergency water could be injected under relatively low pressure. Conversely, if a very small line broke, or there was a small leak in a large line, the system might depressurize slowly. Thus, it is necessary to have the ability to provide emergency coolant to the system while at high-pressure.

The design of safety systems begins by hypothesizing a number of different failures and then developing systems to mitigate the consequences of these failures. Such failures are known as design basis accidents. In order to obtain a license, a plant must show it is protected against the class of design basis

▲PRODIGY(R) interactive personal service 06/25/93 11:33 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR REACTOR

accidents. The broad areas of concern include accidents within the plant as well as accidents involving the handling of radioactive spent fuel. Initiating events must include hardware failures, operator failures, and external events such as tornadoes.

REACTOR ACCIDENTS

In spite of the installation of safety systems, there have been notable accidents at nuclear plants. The first serious nuclear accident occurred (1957) in a British weapons production plant, Windscale 1, an air-cooled graphite reactor. During heat-up operations that were conducted to heal defects in the graphite, it caught on fire and melted some of the fuel cladding.

Volatile fission products, most notably iodine and cesium, were released into the environment around the plant. The Windscale plant and its twin unit were shut down and taken out of service.

Three Mile Island

The most serious U.S. commercial reactor failure occurred on Mar. 28, 1979, at the Three Mile Island (TMI) reactor near Harrisburg, Pa. The TMI-2 accident began as a small break LOCA in which a valve stuck open, allowing coolant to escape from the vessel. The emergency core cooling system (ECCS) operated as designed and provided makeup water for the core. Unfortunately, the operators misinterpreted the information available to them in the control room and shut off the ECCS for several hours. The decay heat from the core boiled off the available water in the vessel, and without adequate cooling, the cladding and fuel started to melt. Before the operators resumed the flow of emergency coolant, a sizeable portion of the core, about one-half to one-third, melted. The molten fuel and cladding dropped into the bottom of the vessel, which was full of water. This water was adequate to quench the molten material. The vessel itself maintained its integrity and kept all of the debris contained.

A sizable amount of gaseous fission products escaped from the vessel through the open valve into the containment building. The containment functioned as the ultimate barrier and prevented a release into the local environment. The small amount of activity that did escape was carried by coolant water that leaked out the valve into the containment and then overflowed into an auxiliary building where the gases leaked

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR REACTOR

into the environment. The releases were almost entirely noble gases (such as xenon), which are chemically inert and not retained within the human body. The health effects of the accident proved to be quite small, and virtually undetectable against the normal incidence of background radiation.

Chernobyl

The accident at Chernobyl Unit 4 in in the USSR in April 1986 has been the most serious of all nuclear accidents to date.

The reactor involved was a water-cooled, graphite moderated reactor, which is used simultaneously for power and plutonium production. The fuel is contained in fuel rods which reside in pipes through which the coolant flows. The design is known as the RBMK. As water in the coolant pipe begins to boil, the effect on the fission rate is positive rather than negative (in contrast to the LWR). The boiling creates a void that allows an increase in the number of neutrons that escape into the graphite moderator and become thermalized. When the thermal neutrons return toward the fuel they encounter less neutron-absorbing hydrogen. As a result, a void will lead to an increase in the heating of the water, which in turn creates more voids, and a self-reinforcing nuclear runaway begins. This characteristic of the RBMK was known to nuclear analysts in the Soviet Union as well as the West. The design is not licensable in the Western nations. The Soviet Union accepted the risks because they did not have the technology to build large pressure vessels until the 1960s.

One of the design basis accidents analyzed at all nuclear plants is the "station blackout." The name refers to the loss of an independent electric energy supply to a nuclear plant. Normally, a plant uses large amounts of electricity to power motors, valves, fans, etc., within the plant itself. For a large plant this requirement might be as large as 5% of the plant generating capacity. The output of the plants own generator can be used during normal operations to provide this electricity. However, when the reactor shuts down, an independent source of electricity is required. A station blackout refers to the loss of the independent supply.

All plants are required to have auxiliary systems, such as batteries or diesel generators, to protect the plant in case of a station blackout. It is also a requirement that a reactor must shut down if there is a loss of off-site power, in order

Copyright (c) 1993 Grolier Electronic Publishing, Inc. All rights reserved.

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR REACTOR

to reduce total plant electric energy needs.

The accident at Chernobyl occurred while plant operators were conducting an experiment to see how long they could extract electricity from a generator as a reactor shut down. The operators knew that instrumentation would detect a loss of

electric supply to coolant pumps and would automatically start the plant emergency core cooling system. To prevent this from happening and ruining the test, the operators disconnected the ECCS, in violation of standing safety rules. Further, the operators wanted to start the test from low-power conditions, but had trouble adjusting the power level appropriately. To assist in maneuvering the power level they withdrew more control rods than would be allowed during normal operations. By the time the test had begun, the control rods were almost useless. They had a long distance to travel before they could affect the fission rate, and the mechanical design was such that it took them too long to travel into the core and stop the accident.

The operators began the test by stopping the flow of steam to the turbine. Without removal of energy the coolant temperature increased to the point where boiling began and voids formed in the coolant channel. The fission rate then accelerated, producing more energy and heating the coolant further. The operators detected the power excursion, but were unable to insert control rods in time to prevent a massive surge of energy that ruptured the fuel rod cladding and distorted the fuel channels. The ECCS was unavailable to cool the core and reduce the accident consequences.

Some uncertainty remains as to the sequence of events that led to the reactor catching on fire. The generally accepted scenario is that molten fuel came in contact with coolant water and reacted to generate huge volumes of steam that ruptured the piping. Subsequently, a second explosion occurred due to a chemical reaction of the incoming water and the hot metals and graphite in the core. The combination of events broke the barriers containing the fission products and allowed them to escape into the environment.

The RBMK design does not include a Western-style containment building, thus once the fission products escaped from the cooling system they had easy access to the environment. About one-half of the radioactivity released emerged in the first few

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR REACTOR

hours of the accident. The remainder escaped over the next ten days as the reactor burned. Only when the core was smothered

in sand and various neutron-absorbing materials did the release cease. Post-accident calculations indicate that a western containment building would have prevented much of the large release of radioactivity.

NUCLEAR REGULATORY COMMISSION

The Nuclear Regulatory Commission (NRC) is an independent U.S. government agency that is responsible for licensing and regulating civilian uses of nuclear materials. Its predecessor, the Atomic Energy Commission, was established in 1946 to succeed the Manhattan Engineer District of the Army Corps of Engineers, created during World War II to develop the atomic bomb (see MANHATTAN PROJECT). The NRC came into existence in 1975 under the provisions of the 1974 Energy Reorganization Act, along with the Energy Research and Development Administration (ERDA). ERDA was later abolished and its functions transferred to the Department of Energy.

The major concern of the NRC is the use of nuclear energy to generate electric power. It licenses the construction and operation of nuclear reactors and other nuclear facilities as well as the possession, use, processing, transport, handling, and disposal of nuclear materials. (The U.S. Department of Energy has authority over U.S. nuclear weapons plants).

NRC policies and practices have drawn fire from various groups concerned with environmental safety. The agency has been criticized for failing to take prompt action where nuclear plants were found to be violating the NRC's own standards; for failing to insure that workers were properly trained; and for lagging in its investigations of mismanagement and criminal activities at nuclear plants.

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR STRATEGY

Nuclear strategy is the art of acquiring, deploying, and using force for political purposes. Because nuclear weapons are so much more powerful than any armaments previously known, their introduction required a rethinking of strategic principles.

Nuclear strategy developed in the shadow of the COLD WAR, a period of continuing political struggle between the United States and the USSR. Although the disintegration of the Soviet Union in the early 1990s ended the cold war, thousands of nuclear weapons still remain, principally in U. S. and Russian hands. This article describes the strategic rationale behind the creation of these weapons and the new problems emerging in the wake of the cold war.

Deterrence

The major political purpose of nuclear weapons, and the centerpiece of traditional U. S. strategy, has been deterrence, or prevention by threat: State A seeks to prevent state B from attacking, by threatening to respond forcefully to an attack. If B takes the threat seriously and refrains from attacking, A's deterrence policy has succeeded. Nuclear weapons lend themselves particularly well to deterrence because they can inflict enormous damage on an enemy. Deterrence thus became the principal--indeed, some have argued, the only--strategic purpose that nuclear weapons serve.

The logic of the nuclear deterrence strategies of the super powers reflects the enormity of the punishment that a nuclear-armed deterrer would be capable of inflicting on the homeland and society of an aggressor. This property was expressed by the phrase "assured destruction," coined in the early 1960s to describe the standard that the U. S. arsenal had to meet. It had to have the capacity to destroy between one-fifth and one-third of the Soviet population and between one-half and three-fourths of Soviet industry in a retaliatory strike, even after absorbing an all-out Soviet attack.

Both the United States and the USSR achieved this capacity in the 1960s. Neither could attack the other without risking an annihilating retaliatory salvo. Theirs became a relationship whose stability was founded on the mutual capacity for assured destruction, the so-called balance of terror. Although in part a deliberate policy, mutual assured destruction (MAD) was

principally a consequence of the weapons that each side had

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR STRATEGY

acquired. In this MAD situation neither side possessed significant incentives to rush to strike first during times of crises, and both saw war as a tragedy to be avoided.

The easing of cold-war tensions during the later 1980s, the signing (1987) of the Intermediate-Range Nuclear Forces (INF) Treaty, and the continuing U.S.-Soviet negotiations on long-range nuclear missiles seemed to signal the waning of the era in which nuclear deterrence was a central element in world affairs (see ARMS CONTROL).

Nuclear Weapons

At the end of the 1980s the vast majority of the world's nuclear weapons were in the possession of the United States and the Soviet Union. These weapons are classified in a number of ways (see NUCLEAR WEAPON), but the most important distinctions among them involve the delivery systems that carry the nuclear warheads to their targets. Long-range delivery systems, capable of reaching into the adversary's homeland and threatening it with massive destruction, are of three basic types. Manned aircraft carry free-falling gravity bombs. Land-based and submarine-launched intercontinental BALLISTIC MISSILES (ICBMs and SLBMs) are self-powered and self-guided and can reach their targets within 30 minutes. The hybrid CRUISE MISSILE, a small, pilotless drone, can be launched from land, ships, or planes.

In cold-war strategy, delivery systems were often judged by whether they reinforced or undercut the stable mutual deterrence associated with MAD. Systems that possessed the accuracy and yield to destroy the adversary's nuclear weapons and that, if used preemptively, threatened to disarm the adversary and destroy his ability to retaliate, were described as "first-strike" systems. "Second-strike" weapons were those that could survive an adversary's first blow but lacked the accuracy to destroy hardened targets--and which would, therefore, be targeted at enemy cities. Because they would provoke a response in kind, these would be useful only in retaliation, as the agents of assured destruction. Unlike

first-strike weapons, second-strike weapons were therefore seen as contributing to stable deterrence.

Because weapons vulnerable to an enemy's first strike could only be used in a first strike of one's own, the

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR STRATEGY

invulnerability of nuclear arsenals was a key to stable deterrence. Since submarines cannot be readily tracked and destroyed, submarine-launched missiles were regarded as the least vulnerable part of the superpower arsenals and an important contributor to stability. Missiles deployed on land, even if housed in reinforced concrete underground silos, became increasingly vulnerable as targeting accuracy improved. Because greater accuracy is required to knock out hidden, protected, or mobile missiles than to pulverize cities, highly accurate weapons have been viewed as particularly suited for first-strike attacks.

All of these theoretical distinctions did not, however, translate perfectly into policy. Both the United States and the USSR took steps to improve their capacities for retaliation by reducing the vulnerability of their nuclear weapons. At the same time, both arsenals became steadily more accurate. Yet deterrence produced stability because each side had so many weapons--and so many weapons deployed in relatively invulnerable ways--that in a preemptive strike, neither could hope to knock out all of the other's armaments. Terrible retaliatory punishment still awaited the attacker.

Evolution of Nuclear Strategy

The first atomic bombs, dropped on the cities of Hiroshima and Nagasaki in 1945, were used, like conventional bombs, to crush the morale of the Japanese. In the decade following the end of the war, however, nuclear weapons became more central to U. S. foreign policy, and their strategic purposes began to change. The United States undertook to defend Western Europe and--after the Korean War--a number of Asian countries against Communist attack by threatening a nuclear response, "massive retaliation," to aggression of any kind.

As the USSR built its own arsenal of ICBMs this strategy changed in two ways. First, the U. S. government sought to

protect its nuclear striking force against a Soviet preemptive attack by reducing the vulnerability of its weapons. Second, it sought to develop forces that could resist Communist aggression of all types without resorting to nuclear war. This was the policy of "flexible response": the United States would attempt to halt a nonnuclear attack on itself or its allies with nonnuclear means.

Flexible response was the last major change in U. S.

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR STRATEGY

strategy, and from the 1960s to the 1980s it remained the official U. S. doctrine. During this period both the United States and the USSR built nuclear arsenals many times larger than needed to guarantee assured destruction. For the United States, the principal reason for this surplus was the need to ensure the "credibility" of its commitment to Asia and Europe. More generally, the U. S. government believed that deterrence would be enhanced if it could match the Soviet Union at every level of force. Thus, one rationale for the controversial land-based highly accurate MX MISSILE was that it would match similar Soviet weapons.

Dilemmas of Nuclear Strategy

In a large-scale nuclear war, each side would suffer such catastrophic destruction that neither could regard the outcome as a victory. To provide any chance for meaningful victory, a nuclear war would therefore have to be severely limited. But the prospects for controlling a nuclear war are at best uncertain. Possibly the combatants would be able to restrain themselves and avoid massive damage. The history of wars between great powers, especially in the 20th century, reveals, however, a willingness to escalate.

Further, nuclear war would certainly create a thoroughly unfamiliar environment, one likely to be more chaotic than any known before. Thus, even if both sides wished to do so, the great nuclear powers might quickly lose the means to limit the war's extent. The electronic-signal-obliterating effects of an ELECTROMAGNETIC PULSE and the disastrous climatic aftermath, worldwide, of the hypothesized "nuclear winter" were other possible catastrophic results of a nuclear conflict.

Nuclear Defense

The stable nuclear standoff between the superpowers rested on the absolute supremacy of each side's offensive capability, the essence of assured destruction. The development of the means to defend against nuclear attack--to destroy the enemy's missiles in flight (see ANTIBALLISTIC MISSILE)--would transform nuclear strategy. On the one hand, it might reduce the effectiveness of an adversary's attempted first strike, as well as offering the hope of surviving a nuclear war. On the other hand, by reducing the adversary's capacity to inflict retribution after being attacked, nuclear defenses might

Copyright (c) 1993 Grolier Electronic Publishing, Inc. All rights reserved.
▲PRODIGY(R) interactive personal service 06/25/93 11:36 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR STRATEGY

destabilize the nuclear balance, increasing the risk that during a crisis one or both sides might choose a preemptive strike. It was for this reason, as well as to prevent an arms race, that the United States and the USSR agreed to severe limits on nuclear defense in the 1972 SALT I agreements.

As a practical matter the task of defense against large-scale nuclear attack is difficult, perhaps impossible, when each side has thousands of weapons that can be launched from different directions, at different speeds, and with decoys to confuse the defense. To stop all of them is unlikely, and, if only one penetrated a defensive system, it could cause catastrophic damage.

Despite its possibly destabilizing consequences, the idea of defense is appealing, and new defensive technologies have constantly been studied by the superpowers. A variety of systems, both ground-based and space-based, are being developed under the U. S. STRATEGIC DEFENSE INITIATIVE (the Star Wars program).

Nuclear Strategy after the Cold War

In June 1992 U. S. president George Bush and Russian president Boris Yeltsin agreed to slash their nations' strategic nuclear weapons arsenals, over a period of ten years, from 22,500 warheads to a combined total of about 7,000. Because they were regarded as the weapons posing the most

danger of a preemptive first strike, the agreement specified the elimination of the multiple-warhead, land-based MIRVED MISSILES deployed by each side. Both sides would continue to possess SLBMs. The effect of the agreement would be to reduce the effectiveness of a surprise attack by either side.

Many of the thousands of warheads designated for elimination are stationed throughout the former Soviet Union, some in the territory of republics other than Russia. Concerns remain about the willingness of these republics to relinquish nuclear weapons. Further, assuming that weapons designated for elimination reach weapons-dismantling plants, there exists the problem of what to do with the tons of enriched uranium and plutonium that remain after dismantling. This material is difficult to use as fuel in nuclear power plants without costly, environmentally dangerous procedures, and there are no ready facilities, either in Russia or the United States, for

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR STRATEGY

burying it safely.

Strategies to Confront Nuclear Proliferation

Perhaps the most pressing nuclear problem since the ending of the cold war is that of nuclear proliferation. It has become increasingly difficult to prevent advanced Third World states from developing nuclear weapons if they desire them. Attempts to police the use of nuclear technologies and fuels through inspections and controls imposed by the INTERNATIONAL ATOMIC ENERGY AGENCY have been useful in slowing proliferation, but in the end nonproliferation is likely to rest on political judgments--for example, can a nation adequately protect its security without nuclear weapons? Will the political costs of acquiring them be prohibitive?

Thus, with the end of the cold war, nuclear strategy is likely to focus increasingly on the problems of stopping proliferation, deterring aggression by small nuclear powers, and preventing the use of nuclear weapons in regional wars. In the same month that Presidents Bush and Yeltsin concluded their dramatic arms-cut agreements, the United States announced that it would continue to maintain a nuclear force and, to this end, would continue its program of nuclear testing.

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR WASTE

Nuclear waste refers to the entire array of radioactive materials created by all aspects of nuclear technology. The most widely known wastes are those produced by the civilian nuclear industry and the nuclear weapons program. Other sources of nuclear waste include radioactive materials produced for medical, research, and industrial applications, and the contaminated sections of dismantled nuclear facilities.

Radioactive materials all decay by emission of various forms of radiation--gamma rays, alpha particles, electrons, positrons, and neutrons. A decay is characterized by the type of emission, the energy of the emitted radiation, and the rate at which decay occurs. The decay rate is usually measured in terms of the half-life, or the time required for one-half of the radioisotope present to decay. Half-lives for different isotopes may range from less than a millionth of a second to billions of years (see RADIOACTIVITY).

The concern with radioactive materials is that the emitted radiation may interact with the human body and cause damage to

cells. The effects of exposure can vary--from mild, temporary illness to death--and can be immediate or delayed, depending upon the amount of radiation received. Although thresholds had been established below which it was believed that there were no ill effects, the current consensus is that any irradiation will cause cell damage, and hence it should be assumed that there is no threshold (see RADIATION INJURY).

Types of Nuclear Waste

Nuclear wastes are usually characterized by their physical and chemical properties and their source of origin. In the United States all wastes from the nuclear defense program are termed military wastes, and are usually treated separately. Civilian wastes with a low-level of radioactivity are termed low-level wastes. These include slightly contaminated materials from nuclear-power facilities, research laboratories, hospitals, and industrial sites. A large source of low-level waste are mill tailings, the residues of uranium ores that have been crushed, ground and chemically treated to extract the uranium.

The major source of high-level waste, which contains large amounts of radioisotopes, is the spent fuel from nuclear power reactors. The reprocessing of fuel from civilian nuclear plants is the responsibility of the U.S. government, which

Copyright (c) 1993 Grolier Electronic Publishing, Inc. All rights reserved.
▲PRODIGY(R) interactive personal service 06/25/93 11:36 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR WASTE

has not yet established a reprocessing program. The spent fuel from military reactors is reprocessed, and the residues of this treatment are also high-level wastes.

The final waste category is called transuranic waste, which includes materials contaminated with man-made radioisotopes created by transmutation of uranium. The most common transuranic is plutonium. The amounts of radioactivity are usually small, but the transuranics emit alpha particles which are particularly hazardous to human tissue. The greatest concern is that transuranic material might be inhaled and lodge in the lungs where it could do great damage.

The total amount of low-level waste generated at a single, large, nuclear-power plant is about 1,000 cubic meters (1,300 cubic yards) each year. The total volume of nuclear-industry

waste generated annually is about 100,000 cubic meters (130,000 cubic yards). Other activities, particularly medical, generate about the same volume each year. Much effort is under way to find means to reduce the volume, either by compaction or by incineration.

A large nuclear reactor discharges about 30 metric tons (33 U. S. tons) of spent fuel each year. The volume of the waste is about 12 cubic meters (15.7 cubic yards), approximately the volume of a standard-size automobile. Total spent fuel production in the United States is about 1,500 metric tons (1,650 U. S. tons) per year, with an accumulated inventory of 15,000 tons.

Nuclear Waste Disposal

The disposal of low-level waste is technically simple since the activity of the material is quite low. A small amount of shielding, such as provided by one meter of soil, is sufficient to protect human beings. The current storage methods are all some form of shallow land burial, and the concern is that water seepage may cause some materials to migrate out--a problem that might be solved by adequate design, management, and monitoring of the site.

In 1980, Congress gave states the primary responsibility for, and regulatory control over, their low-level wastes. The subsequent development of repositories has been a slow process, as states attempt to define appropriate controls.

▲PRODIGY(R) interactive personal service 06/25/93 11:37 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR WASTE

High-level waste from spent nuclear fuel is a collection of many different radioisotopes with highly varying half-lives. It would require about 1,000 years for the total level of activity to decay down to the same level as the ore used to produce the fuel. Even after 1,000 years the composition of the fuel would be quite different from the ore and would still require its isolation from human beings.

The scope of the waste program is demonstrated by the situation throughout the U. S. weapons-production system, whose operations, now suspended, are under the control of the

Department of Energy. The Hanford complex in Washington State, and the Savannah River complex in South Carolina, for example, both contain reactors for producing weapons-grade materials and sites for the storage of nuclear wastes. Hanford also processes spent fuel sent to it from other military reactors. The wastes generated by the complexes themselves and the wastes transported to the sites from other weapons-production plants have been stored in shallow burials, in open pits and basins, or in large metal tanks that have begun to leak, contaminating soil and groundwater. Among possible solutions is the incineration at extremely high temperatures of contaminated soils and other solid wastes, producing a vitrified, or glassy, slag that, while still radioactive, can be more safely stored; and the treatment of liquid waste by mixing it with cement and burying it in concrete-lined pits.

Options for long-term storage all involve some form of burial. The concern with all forms of burial is that over long periods of time the enclosing materials will corrode and fail, allowing radioactive material to migrate into the water table or out into the atmosphere. Additionally, ground motion, such as would occur in an earthquake, might allow the escape of radioactivity. It has been suggested, however, that high-level wastes, vitrified at high temperatures or stored in corrosion-resistant canisters, might be placed underground in salt domes, tuff (ancient volcanic ash deposits), or granitic rock. Salt is of interest because the domes are theoretically free of water and should self-seal if disturbed by ground motion. A proposed repository for high-level wastes is in the tuff of Nevada's Yucca mountain--although doubts about possible volcanic activity in the region have delayed final decisions.

Granite formations are good potential sites because of the rock's low permeability and porosity, and its very high thermal

ACADEMIC AMERICAN ENCYCLOPEDIA

NUCLEAR WASTE

conductivity--an important consideration, since it suggests that temperatures near the stored wastes would not rise so high as to promote container failure but would instead be absorbed by the surrounding rock. There is some uncertainty about granite fracture characteristics under stress and the likelihood of water intrusion. Several European countries, however, appear to favor storage in granite formations.

EPIDEMIOLOGY

{ep-i-dem-ee-ahl'-uh-jee}

Epidemiology, traditionally, is the description of epidemics, which are occurrences of diseases that significantly affect

various groups of people. It studies such factors as an illness attack rate, which describes the number of people ill in a population at risk of being ill. Historically, epidemiology has been applied to studies of INFECTIOUS DISEASES, but in more recent times epidemiologists have also studied major noninfectious diseases, such as cancer and heart disease, and other important health problems (see ENVIRONMENTAL HEALTH). Pandemics are epidemics that encompass large regions or large numbers of people (see PUBLIC HEALTH).

Investigators using epidemiologic techniques have been able to describe diseases in great detail years before the causative agent was identified. In 1854, John Snow investigated and described an epidemic of cholera in London, which he determined resulted from contaminated water from one well. Snow's investigation of the cholera epidemic occurred years before the identification of the bacillus that causes cholera. More recently, epidemiologic studies resulted in detailed descriptions of hepatitis, Lassa fever, Legionnaires' disease, and toxic shock syndrome before their causative agents were identified. The correlation between smoking and lung cancer was obtained from epidemiologic studies, as well. Much epidemiological research is now devoted to AIDS (see AIDS).

Epidemiology involves various techniques, the foremost being the descriptive approach, in which the disease or situation is defined in terms of time, place, and person. Long-term and short-term trends in the occurrence of the disease are considered. The geographic area where the causative agent and the ill person had contact is noted; for example, someone may eat a contaminated meal in a restaurant and become ill the next day at home, but the contact point was the restaurant. The patient's age, sex, socioeconomic status, occupation, nutritional status, and other factors are also recorded.

In an epidemiologic investigation, the existence of an epidemic first must be confirmed by examining individual cases and verifying the diagnosis. The number of cases is then estimated, and the clinical data are collected and analyzed. A case definition is developed that is then used to identify other cases. Appropriate laboratory specimens are obtained and

▲PRODIGY(R) interactive personal service 06/25/93 11:38 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

EPIDEMIOLOGY

processed, and the data are analyzed in terms of time, place, and person. The source of the causative agent, its mode of transmission, and the risk factors that explain why certain people became ill and others did not are determined. A hypothesis is formulated as to why the outbreak occurred, and specific investigations are conducted to prove or disprove the hypothesis. Once the cause of the outbreak is identified, appropriate control and prevention measures are usually instituted. Such public-health organizations as the CENTERS FOR DISEASE CONTROL and the WORLD HEALTH ORGANIZATION investigate and attempt to control epidemics. PHILIP S. BRACHMAN, M.D.

ACADEMIC AMERICAN ENCYCLOPEDIA

ENVIRONMENTAL HEALTH

The expanding field of environmental health encompasses various scientific disciplines in order to investigate the physiological impact of environmental conditions on human health.

Since the late 1960s, information concerning the affect of environmental factors on health has proliferated. This substantial gain of knowledge comes from many scientific disciplines, including biology, chemistry, physics, mathematics, and engineering sciences. Increasing sophistication of laboratory techniques, diagnostic equipment, and in-the-field surveillance has greatly contributed to the prevention and control of human health problems by enabling environmental factors to be analyzed in minute quantities.

OCCUPATIONS AND AGENCIES

Occupations in environmental health include medicine, ecological research, pollution sciences and engineering, and regulatory enforcement through governmental organizations such as the ENVIRONMENTAL PROTECTION AGENCY (EPA), FOOD AND DRUG ADMINISTRATION (FDA), OCCUPATIONAL SAFETY AND HEALTH ADMINISTRATION (OSHA), PUBLIC HEALTH Service, and state and local environmental agencies.

Public health departments routinely inspect meat, fish, and poultry packaging industries, restaurants, markets, and hospitals, and enforce regulations designed to prevent the contamination of food, beverages, drugs, and cosmetics. The Environmental Protection Agency is empowered to protect the public health by controlling air and water pollution and by regulating the production, use, and disposal of toxic chemicals. The Food and Drug Administration is responsible for overseeing the wholesomeness of products consumed in the United States and for the banning and control of harmful chemicals in food, cosmetics, and drugs. The Occupational Safety and Health Administration supervises work environments to protect workers from exposure to unsafe industrial chemicals, machinery, and operating procedures. Most cities have sanitary engineering departments responsible for garbage collection and sewage treatment. Communities frequently chlorinate drinking water to kill pathogens, ever since John L. Leal demonstrated (1908) the efficacy of chlorinated waters in Jersey City, N.J. Research currently focuses on environmental pollution (see POLLUTION, ENVIRONMENTAL) and its consequent harm. Adverse health effects resulting from environmental contaminants, or

ACADEMIC AMERICAN ENCYCLOPEDIA

ENVIRONMENTAL HEALTH

pollution, are an important concern of most environmental health research. When industrialization was in its infancy, the impact of pollution was localized and minimal. With rapid worldwide industrialization, however, using PETROCHEMICALS as an energy base, toxic pollution has increased to global proportions. The stress placed on our planet by pollution has far-reaching effects and constitutes a grave crisis.

COMMUNICABLE DISEASES

History

Environmental health originated in the control of communicable diseases during the past century. The most spectacular achievement of the biological sciences in the last hundred years has been the identification of pathogenic organisms as the cause of disease. The germ theory of disease, pioneered by Louis PASTEUR and others, led to the general concept that disease could be prevented by vaccination and controlled by interrupting the transmission of pathogenic organisms to humans.

Three 19th-century scientists contributed greatly to understanding the causes and prevention of INFECTIOUS DISEASE: Peter Ludwig Panum, who researched (1847) measles; John Snow, who published (1849) findings on the mode of cholera communication; and William Budd, who wrote (1873) about the spread of typhoid fever from contaminated water supplies in Wales and England.

Certain animals, such as mosquitoes, flies, fleas, lice, rats, mice, and snails, were found to harbor pathogenic organisms and parasites that can cause human diseases. As a result of this major discovery, populations of these host animals, known as vectors, were controlled through eradication and better sanitation, reducing the prevalence of disease. The recognition that disease could also be transmitted by fecal contamination of water and food led to the development of sewage treatment, systematic garbage collection, the protection and treatment of drinking water supplies, and the establishment of public health enforcement agencies.

Results of Control

The prevention and control of communicable disease in

06/25/93

11:39 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

ENVIRONMENTAL HEALTH

industrial societies began to show dramatic results during the 1920s. Incidences of such major epidemic diseases as BUBONIC PLAGUE, DIPHTHERIA, MALARIA, SCARLET FEVER, SMALLPOX, and WHOOPING COUGH dropped radically. Conversely, human life expectancy in developed nations began to rise from less than 40 to more than 75 years. Through the intensive efforts of the World Health Organization (WHO) and the cooperation of all nations, endemic smallpox appears to have been eradicated; the last case of endemic smallpox occurred on Oct. 26, 1977, in Somalia. This achievement marks the first time in human history that a communicable disease has been eliminated. The smallpox virus is apparently extinct except for laboratory cultures. Ironically, smallpox outbreaks associated with laboratory accidents have occurred since 1977. As a result, the WHO insisted that all existing cultures be destroyed, except for those in four tightly guarded places, including the Center for Disease Control (CDC) in Atlanta, Ga. These remaining cultures are available for research purposes and also for producing vaccines should mutations of smallpox-type viruses arise.

Legionnaires' Disease

Developed nations have instituted public health and enforcement systems to reduce the occurrence of disease. In the United States, many diagnosed diseases must be reported to state officials and to the CDC, where information is compiled and disease incidence is surveyed. Teams of experts are thus available and easily mobilized to investigate disease, as was necessary during the mysterious pneumonialike outbreak at an American Legionnaires Convention (1976) in Philadelphia. After several months of intensive investigation, a particularly elusive and previously unknown bacterium was found to be the cause of the infection now known as LEGIONNAIRES' DISEASE. This bacterium as well as a group of similar bacteria now isolated are believed to be responsible for as many as 5 to 10 percent of deaths diagnosed as pneumonia.

Nosocomial Diseases

Hospitals cooperate in environmental health concerns by hiring and training specialists to curb the rising incidence of NOSOCOMIAL infections, which result from exposure to pathogens during a hospital stay. The cross-contamination of sick patients is prevalent, as is transmittal of an infection from

▲PRODIGY(R) interactive personal service 06/25/93 11:39 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

ENVIRONMENTAL HEALTH

the hospital staff to patients. Because DRUG therapy is widely employed, hospitals have been shown to be the breeding grounds of antibiotic-resistant organisms. At present, hospitals are placing great emphasis on the identification and control of these organisms and on tighter control of the spread of infection.

CHRONIC AND DEGENERATIVE DISEASE

Although the prevalence of diseases caused by pathogens and parasites has declined substantially, chronic illnesses and degenerative disorders have become the leading causes of death in developed nations.

In the United States, the only epidemic disease still prevalent is gonorrhea, having doubled in annual cases from 1969 to 1976. The four leading causes of death are, in order, HEART DISEASE (cardiovascular disease), CANCER, central nervous disorders (cerebrovascular disease), and accidents. The first three of these are chronic and degenerative disorders. The greatest percentage of accidental deaths involve the automobile, which is also responsible for up to 90 percent of the air pollution in most cities.

FACTORS CAUSING DISEASE

A major difficulty in the control and prevention of chronic and degenerative illnesses such as cancer, RESPIRATORY SYSTEM DISORDERS, and heart, liver, and kidney disorders is that the symptoms are caused by complex factors. Differing forms of cancer have myriad probable causes, each exerting influences over the course of time. Most chronic illnesses are not caused by any single etiologic agent, for example, a pathogenic organism. Smallpox could be eradicated because its virus was

isolated and a vaccine produced; a vaccine for heart disease, however, appears unlikely.

More important, with an infection by a biological agent, the onset of disease symptoms is usually a matter of hours, days, or weeks. On the other hand, the onset of cancer from exposure to carcinogens, which are chemical agents, may take years, even decades. Epidemiologic research is complicated by such factors as the length of exposure (whether in inhalation, ingestion, or skin contact), the stress of the individual, and the toxicity of the agents involved. Some agents become toxic when present

Copyright (c) 1993 Grolier Electronic Publishing, Inc. All rights reserved.
▲PRODIGY(R) interactive personal service 06/25/93 11:39 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

ENVIRONMENTAL HEALTH

in the human body in conjunction with other agents. Other agents that are already toxic become even more powerful in the presence of other chemical compounds. For example, deaths from cardiac and respiratory failures have resulted from the effects of combining sleeping pills and alcohol.

THE CHEMICAL ENVIRONMENT

Each year, hundreds of new chemical substances are created. Because many of these chemicals differ significantly from natural biochemicals, detailed studies have been designed to discover potential harmful effects. Often, when synthetic compounds are introduced into the environment, their movement through ecosystems is difficult to detect. Many compounds are not biodegradable and are of particular concern, especially if they can accumulate in biological organisms, including humans. Since the beginning of the century, the environment has been progressively polluted by chemicals. Two examples of biologically persistent chemicals that have been indiscriminately introduced into the environment in vast quantities are the insecticide DDT (dichlorodiphenyltrichloroethane) and a group of compounds known as polychlorinated biphenyls (PCB).

DDT

DDT is probably the best-known synthetic compound, and its environmental effect is of great magnitude. The actual DDT activity is not fully understood, even though it has been studied for over thirty years. DDT was originally hailed as

the great savior of crops from insect pests and has been extremely important in controlling the spread of malaria by mosquitoes. However, because DDT and its related compounds can dissolve into fatty animal tissue, DDT has bio-accumulated through food chains and has manifested pronounced effects in fish, reptilian, and avian metabolism and reproductive systems. Many animal species have suffered substantial reductions of populations from DDT contamination, including the bald eagle, the national bird of the United States.

PCB

Materials containing PCB were used primarily in electrical transformers because of their unique capacity to conduct electricity and because of their fire resistance.

Copyright (c) 1993 Grolier Electronic Publishing, Inc. All rights reserved.
▲PRODIGY(R) interactive personal service 06/25/93 11:40 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

ENVIRONMENTAL HEALTH

Unfortunately, PCB compounds have also been shown to be highly carcinogenic.

Massive amounts of PCB have been introduced into the environment. More than 1,500,000 kg (one-third of the nearly 1 billion lb) of PCB-containing material manufactured since the 1920s has been discharged into waterways or leaked from improper disposal sites. Little information is currently available concerning the bio-accumulation effects of PCB, which is, like DDT, soluble in fatty tissue.

DDT and PCB are present worldwide, having been found in ocean sediments and polar ice. The problem of tracing these compounds and thousands of others (including breakdown products which sometimes are even more harmful) is immense and will occupy the investigations of environmental health researchers for years to come.

EFFECTS OF AIR POLLUTION

The dangers of air pollution have been well documented. Air pollution kills, especially when prolonged weather inversions prevent adequate dispersion of petrochemical combustion products.

During Dec. 5-8, 1952, a killer smog was responsible for an

estimated 3,500-4,000 deaths in London. In 1948, a stagnant air mass sent over 10 percent of the population of Donora, Pa., to hospitals.

Most urban communities show increased mortality of the aged, very young, and those afflicted with respiratory illnesses during heavy smog episodes.

Lung Damage

The major forms of air pollution--carbon monoxide, particulates, sulfur oxides, nitrous oxides, and photochemical oxidants--have a wide range of effects on human respiratory tracts.

Disorders include ASTHMA, BRONCHITIS, EMPHYSEMA, and lung cancer. Air pollution results primarily from automobile exhaust, fossil fuel power plants, industrial processes, and forest fires; cigarette smoking has also been strongly linked

ACADEMIC AMERICAN ENCYCLOPEDIA

ENVIRONMENTAL HEALTH

with respiratory illnesses.

The extensive damage of respiratory, circulatory, and lymphatic systems by chronic tobacco inhalation makes cigarette SMOKING a major public health concern.

EFFECTS OF WATER POLLUTION

Mercury Poisoning

One of the most significant harms to human health as a result of water pollution occurred when the people of Minimata Bay in Japan were exposed to mercury-contaminated shellfish and fish caught near the shore. The mercury had been discharged into the water from a local factory. The pollution was not detected until an alarming number of children were born with physical abnormalities.

Public Water

A wide variety of toxic compounds is present in public drinking water supplies, although mostly in minute amounts.

Almost nothing is known about the long-term health effects of these contaminants. Water that is chlorinated in order to eliminate bacterial contaminants may actually increase the toxicity of chemical contaminants. The EPA is extending a list of known and suspected toxic substances and has set limits for the presence of many of these contaminants in drinking water.

EFFECTS OF FOOD AND DRUG CONTAMINATION

Delaney Amendment

FOOD ADDITIVES are chemicals widely used to enhance the flavor, color, texture, consistency, and wholesomeness of foods. Chemicals are also used in the preparation, mixing, curing, firming, anticaking, and preservation of foods.

The Delaney clause of the 1958 amendment to the Food, Drug and Cosmetic Act states that no additive may exist in any food if it produces cancer when fed to a human or laboratory animal in any concentration or if it can be shown to be a carcinogen by an appropriate test. This law has given rise to a substantial chemical testing industry. Because the burden of proof of safety rests with the manufacturer, much debate has ensued over

ACADEMIC AMERICAN ENCYCLOPEDIA

ENVIRONMENTAL HEALTH

the methodology used to analyze toxicity. Several areas of controversy include the accuracy of testing techniques, whether animal studies are useful in testing for human drugs, and the safety of dosage levels.

Contaminants

The contamination of plant and animal foods is another concern in environmental health. The effects of petrochemical FERTILIZERS, HERBICIDES, PESTICIDES, and STEROIDS and other growth-inducing hormonal residues are uncertain. In 1973, more than 10,000 Michigan farm residents were exposed to polybrominated biphenyls (PBBs), a group of fat-soluble, biologically persistent compounds, similar to PCBs, used as flame retardants.

A shipping accident substituted several hundred pounds of PBB for magnesium oxide, a nutrient in animal feed. Exposed cattle

suffered weight loss, decreased milk production, and death; cows gave birth to dead and malformed calves. Farmers, their families, and other people who drank milk and ate meat from these contaminated herds also had symptoms resulting from PBB toxicity. The long-term human health effects of this accident are unknown, and results of continuing research may not be conclusive for years.

Another disaster occurred in the early 1960s, when malformed children were born to mothers who were taking the prescribed drug THALIDOMIDE. Since that time, side effects of medicines intended to improve health have been rigorously examined.

RADIATION

The nuclear age has brought a great form of energy to humans; however, nuclear research, including the creation of plutonium and other radioactive isotopes as well as their improper use and disposal, is of grave public concern. Emissions from radioactive decay are known to cause cancer and genetic damage. Plutonium is the most toxic chemical created, and inhalation of 1/10,000 of a gram can induce lung cancer. The use of plutonium to generate electricity from nuclear power plants is of particular concern, especially in light of the 1979 crisis at the Three-Mile Island nuclear power plant near Harrisburg, Pa., during which radioactive material was released into water and the air. Disposal of radioactive wastes and their safe

▲PRODIGY(R) interactive personal service 06/25/93 11:40 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

ENVIRONMENTAL HEALTH

transport is another concern (see NUCLEAR ENERGY). Atmospheric atomic testing has spread worldwide a radioactive substance, strontium-90, that accumulates in human bones. Strontium strongly mimics the biochemical pathways of calcium, and decay emissions of strontium that have accumulated in human bones may possibly induce leukemia. Close surveillance of survivors of the two atomic explosions in Japan and the inadvertent victims of fallout from atmospheric testing in the Marshall Islands has shown high incidences of LEUKEMIA and skin disorders. The significance of the genetic damage is still uncertain because such studies require long and precise epidemiological research.

DANGERS IN THE WORKING ENVIRONMENT

Many of the early studies of chemically induced diseases were

conducted on workers exposed to certain manufacturing processes. Several specific diseases have been identified in relation to the inhalation of asbestos, silicon, talc, and coal dust. Most occupational diseases fall into two time-concentration patterns--those of quick recoveries from a relatively high dose over a short period, and those of cumulative effects (with a slow onset) of a relatively low dose over a long period of time. Ammonia and carbon monoxide are typical examples of the former, whereas inhalation of benzene and carbon tetrachloride has been shown to be carcinogenic over a long-term exposure.

The work environment has also been studied for the effects of noise on human health. Most notably, loud chronic noise may lead to temporary or permanent hearing loss. Other effects of noise pollution are the loss of intelligible speech, the disruption of sleep patterns, and increased stress of the individual.

PUBLIC HEALTH

Public health is the effort organized by society to protect the health of its members. On all levels--local, national, and international--the major concerns of public health agencies are the assurance of disease-free food and water, adequate sanitation systems, the prevention or control of epidemic and endemic diseases, the delivery of health care to needy population groups, and the formulation of laws regarding health.

Although the knowledge base of the field cuts across a number

of disciplines (biomedical sciences, social sciences, engineering, law), public health research relies heavily on specialized methods of quantitative analysis. The basic techniques for measuring and evaluating community-wide health problems are those of EPIDEMIOLOGY and biostatistics.

History

Concern with the regulation of diet, with the water supply sewage disposal, and the isolation of the sick were already present in early civilizations. During the Middle Ages, efforts to fight infectious disease shaped public health efforts. The BUBONIC PLAGUE pandemic of 1347-51 and the epidemics that followed resulted in such practices as quarantine and sanitary cordons.

During the 16th to 18th centuries, new sociopolitical and economic theories evolved to justify and maintain the power of nation-states. It was believed, for example, that large populations were necessary to supply labor and promote state wealth. In 17th-century England, physician William Petty and John Graunt--considered the first demographer--developed a numerical method for studying the social phenomena that might provide the state with information on the number and "value" of people. The method required accurate statistical data on population, trade, manufacture, and education, as well as disease. This "political arithmetic" marked the beginning of quantitative studies of health of populations.

VACCINATION, discovered (1798) by the English country physician Edward JENNER, was the first practical means to control and eventually to totally eradicate smallpox, as later it was to end the spread of other contagious diseases.

During the early 19th century, public health focus shifted to

ACADEMIC AMERICAN ENCYCLOPEDIA

PUBLIC HEALTH

the health problems associated with industrialization and urbanization: poor working conditions in factories, crowding in tenements, lack of a clean water supply and of effective sewage disposal, poor food, and inadequate medical services. In England in the 1830s and 40s, recognition of these conditions gave rise to the sanitary movement, led by such

notable reformers as Edwin Chadwick, whose book, Report on the Sanitary Condition of the Labouring Population of Great Britain (1842), demonstrated the link between environmental conditions and public health. The movement was responsible for the passage of the Public Health Act of 1848, the first attempt to create an official body to supervise health-related public conditions. Following Britain's example, many United States cities and states founded public health departments in the last half of the 19th century.

The identification of microbes as causative agents of disease allowed public health workers during the late 19th and early 20th centuries to develop specific methods of prevention. Antitoxins and vaccines were discovered and used to control communicable diseases. Mass immunization programs were initiated. Public health laboratories were founded to test the purity of water, food, and milk, as well as to diagnose contagious diseases.

The new impetus given to public health by the application of bacteriology, coupled with the growing health needs of an industrial and urban United States, produced a rapid growth in state and municipal health departments, voluntary health agencies, public health NURSING, maternal and child welfare programs, and school health programs.

The Modern Era

International conferences aimed at drafting sanitary conventions and quarantine regulations led first to the establishment (1909) of an international health organization based in Paris, and ultimately to the founding (1942) of the WORLD HEALTH ORGANIZATION (WHO), an agency of the United Nations. Its broad scope of activities includes worldwide campaigns to control such widespread diseases as malaria, tuberculosis, and the venereal diseases; to help establish pure-water supplies, sanitation systems, and health education; to provide health planning assistance; and to help train health workers.

ACADEMIC AMERICAN ENCYCLOPEDIA

PUBLIC HEALTH

The health services of individual countries are organized in

many different ways. In the Soviet Union, public health is the responsibility of the national government, and its administration is strongly centralized. The United Kingdom allows substantial autonomy to local governments. The United States, with its pluralistic approach to health services, gives local and state governments and the private sector large areas of responsibility. The Public Health Service, the principal health agency of the federal government, however, is among the largest and most varied of federal organizations.

PHS had its beginnings as the Marine Hospital Service (1798-1902), which provided medical relief to merchant seamen. Its functions gradually expanded to include the supervision of quarantine laws, the medical inspection of immigrants, and general investigations in the field of public health. It became the Public Health Service in 1912, and now operates as a division of the Department of Health and Human Services.

Of the many agencies making up the PHS, six are responsible for carrying out its major functions: the NATIONAL INSTITUTES OF HEALTH (NIH), the FOOD AND DRUG ADMINISTRATION (FDA), the CENTERS FOR DISEASE CONTROL (CDC), the Alcohol, Drug Abuse, and Mental Health Administration, the Health Resources Administration, and the Health Services Administration. Important functions of the PHS include medical research and dissemination of research results; the supply of health professionals and facilities to the public, often by working with communities; the provision of medical services to such special groups as American Indians; the investigation of the causes of such epidemics as LEGIONNAIRE'S DISEASE; the testing of foods and drugs to ensure their safety; the development of treatment programs for alcohol and drug abuse and mental health problems; and the collection and analysis of statistical health data.

The National Institutes of Health are responsible for coordinating research into AIDS (Acquired Immune Deficiency Syndrome). Other PHS agencies test the efficacy of anti-AIDS drugs; develop AIDS blood tests; develop safety standards for health workers involved with AIDS patients; and disseminate information and educational programs on AIDS.

ACADEMIC AMERICAN ENCYCLOPEDIA

UNION OF SOVIET SOCIALIST REPUBLICS

The history of the Union of Soviet Socialist Republics began with the seizure of power in Russia by the Bolsheviks (Communists) in 1917 and ended with the dissolution of the Soviet state in 1991. In the intervening time, the lands of the old Russian Empire were governed by the Communist Party of the Soviet Union (CPSU; see COMMUNISM), an organization committed to a radical vision of Russia's future greatness and of the way to achieve it. This vision led to heroic self-sacrifice and blood-chilling crimes. It inspired millions, not only in the Soviet Union but around the world, yet by the early 1990s its inner bankruptcy was exposed.

BACKGROUND

In order to understand the origin of the Communist party's vision, it is necessary to look at the historical character of the USSR's predecessor, tsarist Russia, the challenge it faced from the industrialized West, and debates among the Marxist groups to which the Bolsheviks belonged.

The Tsarist State

Like the United States, the Russian Empire expanded from a small original base until it occupied a vast continent. Unlike the United States, it did not expand into thinly populated and extremely fertile land with little serious interference from other nations; many parts of the Russian Empire were thickly settled, and Russian expansion was observed with suspicion by powerful rivals.

These factors caused the Russian government to take the form of a militarized autocracy ruling over a restive peasantry. At the top was the tsar, who in theory and to a great extent in practice was the possessor of undivided state sovereignty. In the middle was a nobility that depended much more on the central government than the aristocracy in countries such as France and England. At the bottom (besides a small urban population) was a vast multitude of peasant villages. Although the Russian Empire was highly centralized, since all important decisions were made in the capital, it was also under-governed, and the peasants were left to themselves for much of their lives.

During the 18th and 19th centuries, the empire moved beyond its

original population base of Orthodox Russians and incorporated

ACADEMIC AMERICAN ENCYCLOPEDIA

UNION OF SOVIET SOCIALIST REPUBLICS

both non-Orthodox Christian peoples such as the Lithuanians, and non-Christian peoples such as the Muslim Kazakhs and Azeris. The Russian Empire did not conduct wars of extermination, practice racially-defined slavery, or push nomadic peoples onto reservations: it left subject peoples more or less intact with varying degrees of administrative autonomy. Unfortunately, the empire was never able to effectively absorb these large non-Russian populations in a stable way; assimilation was not a success, and neither was granting special privileges. The tsars bequeathed this problem to the Soviet successor state.

The Western Challenge

Despite some military setbacks, the tsarist empire was for a long time able to hold its own in its competition with other European great powers. In the late 19th and early 20th centuries, however, pressure from the West began to intensify. This pressure was threefold. In the economic sphere, Western technological and organizational breakthroughs created a powerful industrial society that outstripped the backward Russian economy. In the political and cultural spheres, invidious comparisons with the West created doubt and disloyalty among influential sections of Russia's educated public. The bottom line was military competition: would the tsarist system be able to protect Russian independence against the new sources of material and social power at the disposal of the West?

The Russian Marxists

The challenge from expansionist Western powers made a radical transformation of Russian society inevitable. The tsarist government embarked on education and industrialization programs somewhat reluctantly, realizing the great potential for social instability in these changes. A great debate arose within educated Russian society over the fundamental choices facing the country. The Russian revolutionary tradition--the radical wing of educated society--rejected tsarism and western models with equal fervor. In 1881, the NARODNIKI (Populists) tried to

incite a peasant rebellion by assassinating Emperor Alexander II. Partly as a result of Populist failures, the next generation of Russian revolutionaries adopted MARXISM and placed their revolutionary wager on the nascent working class.

ACADEMIC AMERICAN ENCYCLOPEDIA

UNION OF SOVIET SOCIALIST REPUBLICS

Marxism predicted a socialist revolution in advanced capitalist countries. How could it be applied to a peasant country that had not even achieved basic political freedoms? In response to this challenge, the Russian Marxists argued that the Russian revolution should be seen in a world context: Russia may have been backward, but the world economy as a whole was ready for SOCIALISM. Many Russian Marxists also felt that in some way the Russian working class might be able to lead the peasantry toward socialism. A central dispute among Marxists was how to organize an effective revolutionary party under the specific conditions of Russian autocracy. The debate on this question caused a deep split into two groups called the BOLSHEVIKS AND MENSHEVIKS; the leader of the Bolsheviks was V. I. LENIN.

THE SOVIET REVOLUTION

In the decade between 1914 and 1924, Russia experienced a national convulsion beyond anything experienced by Western European nations in modern times. In 1914, Russia was drawn into WORLD WAR I and found itself locked in a desperate struggle with Germany and Austria-Hungary. The military challenge proved too much for the monarchy: Russia suffered heavy losses at the front and intolerable social strains at home. In March 1917 the 300-year-old ROMANOV dynasty was overthrown. The Provisional Government that took its place faced an impossible agenda: to carry on the war, to settle the basic principles of a new state, and to carry out important social reforms. In reality, the government could not even guarantee minimum social and economic order. By the time the Bolsheviks seized power in November, the country was in the grip of spiralling disintegration. The Bolsheviks did not take over a government so much as offer to create an effective one. (See RUSSIAN REVOLUTIONS OF 1917.)

The Civil War

Given the conflicts in Russian society and the deep differences in visions of the future, there was probably little chance of avoiding civil war once the unifying figure of the tsar was removed. Armed conflict began in 1918. Between 1918 and 1922 there were so many challenges to Bolshevik rule that it is perhaps better to speak of "civil wars" in the plural. The challengers can be divided into several groups. The Whites, who relied principally on the elite classes of tsarist Russia, were led by former officers such as Aleksandr Kolchak in

ACADEMIC AMERICAN ENCYCLOPEDIA

UNION OF SOVIET SOCIALIST REPUBLICS

Siberia and Anton Denikin in south Russia. National minorities also took advantage of the temporary breakdown of central authority to declare independence. Some--such as Poland, Finland, and the Baltic States--were successful; others were reincorporated into the Soviet Union. There were also peasant rebels, collectively called the Greens. Finally, foreign powers such as Britain, France, the United States, and Japan intervened in order to topple Bolshevism. Because of conflicting purposes and lack of coordination among their enemies, the Bolsheviks survived all these challenges.

The devastation caused by the world war and the civil wars led to an unprecedented collapse of the normal workings of society. The ruthless mobilization policies pursued by all the contending forces, most successfully by the Bolsheviks, compounded the economic hardships. The civil wars began to wind down in 1920. After they ended, Russian society was further weakened by the vast famine of 1921-22 in the Volga region.

The circumstances under which the Bolsheviks came to power had many important long-term consequences. The revolutions of 1917 took place as a result of military defeat, and an essential part of the Bolshevik mandate was to prevent a similar threat to national survival from recurring. The Bolshevik entry onto the world stage was made during World War I, a time when the European nations were showing by word and deed that no price was too high to pay in order to prevail in the competition for power and prestige. Total mobilization of society, ceaseless propaganda, and centralized economic regulation were the techniques the Bolsheviks used to attain victory.

Given the many challenges to its existence, it is not surprising that the Communist party's most crucial accomplishment was the creation--largely by Leon TROTSKY--of a new Red Army out of the ruins of the old Imperial army. Yet this accomplishment could hardly have been predicted: the Bolsheviks were a radical working-class party that had strongly opposed militarism and the war against Germany. They not only had to turn themselves into military commanders, but also had to work with two groups who had little reason to trust them: former tsarist military officers and the peasant recruits who made up the bulk of the army.

The New Economic Policy

Copyright (c) 1993 Grolier Electronic Publishing, Inc. All rights reserved.
▲PRODIGY(R) interactive personal service 06/25/93 11:44 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

UNION OF SOVIET SOCIALIST REPUBLICS

The change in attitude needed for the creation of the Red Army was paralleled in the economic sphere by the NEW ECONOMIC POLICY (NEP) announced in 1921. The essence of NEP was a shift in priorities from a policy of severe pressure on the population for mobilization purposes to a policy of collaboration and active encouragement of increased production. NEP is often portrayed as a sharp turnabout from the radicalism of "war communism" (the name given after the fact to Bolshevik mobilizing policies); in many ways, however, it was the completion of a shift in outlook that had been going on since 1917. Before taking power, the Bolsheviks were a sectarian party who preached class struggle and blamed all problems on elite sabotage. After taking power, they were forced to take responsibility for national problems and to work with groups such as the peasants and the so-called "bourgeois specialists" (professional people). This collaborative perspective coexisted uneasily with the militant class outlook inherited from the past.

The Bolsheviks' struggle to maintain themselves in the midst of breakdown and social collapse led to a bedrock insistence on party unity and discipline. The experience of power confirmed earlier party feelings about the need for a highly disciplined party organization.

INTERNAL CHALLENGES TO COMMUNISM

By 1924 the country had begun to recover from the devastation of the previous decade. Up to this point the tasks faced by the party were so stark that there was relatively little dissension about how to deal with them, but the Bolsheviks now faced more difficult choices.

The Peasants

As the period of economic recovery approached its end, the party had to choose an industrialization strategy. Economic transformation meant imposing new burdens on a peasantry whose support was felt to be vital. The party's feeling of setting off on a new road was heightened by the death of Lenin in early 1924. (He had been completely incapacitated by a stroke for almost a year).

Underlying these challenges was the hard fact that the strategy

▲PRODIGY(R) interactive personal service 06/25/93 11:44 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

UNION OF SOVIET SOCIALIST REPUBLICS

the Bolsheviks had developed was not working. They saw themselves as guarantors of the "dictatorship of the proletariat" (industrial workers) mandated by Marxist ideology, in a country where the overwhelming majority of the people were peasants. Since there was unlikely to be a socialist revolution in the advanced western countries anytime soon, the Bolsheviks had to use internal resources to win over the peasants. In theory, this would be done in the short run by the superior performance of socialized industry, and in the long run by the voluntary transformation of the peasants from primitive individualists to technologically advanced collectivists.

The central difficulty was that the performance of the socialized sector did not justify Bolshevik expectations. There were a number of reasons for this, ranging from the absence of foreign loans to disappointingly low productivity in industry. Without dynamic industrial growth, the Bolsheviks could not count on peasant loyalty. Furthermore, the slow tempo of growth seemed to leave Russia open to attack from a hostile capitalist world.

The Nationalities

The Bolshevik strategy for dealing with the nationalities faced similar dilemmas. Lenin strongly believed in the economic rationality of belonging to a large political unit such as the tsarist empire. It was, of course, understandable that the smaller nationalities wanted independence: under tsarism, they had indeed been oppressed solely because of their nationality. But Lenin was confident that if the irritant of national oppression was removed, people would no longer need to see themselves primarily as Georgians or Uzbeks--instead, they would realize their "true" identity as members of the working class.

This thinking lay behind the reorganization of the tsarist empire into a Union of Soviet Socialist Republics. In 1922, a treaty was signed by the Russian Federation, Ukraine, the Transcaucasian Republic, and Belorussia. Within the largest republic, the Russian Federation, a further effort was made to ensure that each national grouping had administrative expression at some level. Even though their ultimate aim was to move beyond nationalism, the Bolsheviks paradoxically made it the organizing principle of the new state. This strategy

▲PRODIGY(R) interactive personal service 06/25/93 11:44 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

UNION OF SOVIET SOCIALIST REPUBLICS

entailed a severe risk. If nationalist consciousness did not fade away as expected, it would be strongly entrenched in the new administrative framework and represent a standing challenge to the unity and centralization required by a socialist state and society.

Party Leadership

After Lenin's death, the party faced the further dilemma of preserving unity without the original founder of Bolshevism. As the disquieting difficulties of socialist construction became apparent, various groups began to express opposition to the policies of the party majority. Conflicts over policy were compounded by divisions among the top leaders, who were unable to work together in a collective leadership. But all opposition within the party was ultimately crippled by an insistence on party unity that was shared by all party members, including the oppositionists themselves. In 1927, such outstanding Bolshevik leaders as Leon Trotsky, Grigory ZINOVIEV, and Lev KAMENEV were expelled from the party. Opponents of central policy after 1927 (most notably Nikolai

BUKHARIN and Aleksei Rykov) made almost no effort to take their case beyond top party bodies; they were easily defeated and removed from responsible posts.

THE CONSOLIDATION OF THE STALIN REGIME

The ultimate winner in these intraparty disputes was Joseph STALIN. While other leaders were busy giving speeches, Stalin used his position as general secretary of the party to work on the nuts and bolts of party rule: appointments and coordination of policy at all levels of the huge Soviet state. What his opponents saw as machine politics was viewed by supporters as practical concern for the unity of the party. Stalin was not an eloquent speaker, but he did embody the party's will to "catch up and overtake" the advanced western countries by building "socialism in one country"--Russia.

By 1929, Stalin was in undisputed control, and in a position to give his own response to the dilemmas facing the party. He decided that certain key Bolshevik aims had to be maintained even if it meant the sacrifice of all others. These aims were rapid industrialization, unity in party and society, and vigilance against class enemies.

Industrialization

Copyright (c) 1993 Grolier Electronic Publishing, Inc. All rights reserved.
▲PRODIGY(R) interactive personal service 06/25/93 11:44 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

UNION OF SOVIET SOCIALIST REPUBLICS

Stalin pushed for industrialization at a rate faster than anyone in the party had earlier dreamed was possible. He maintained that the inhuman tempo of growth was necessary if Russia did not want to be beaten by its many enemies. Other socialist values such as equality or democracy would have to wait until the period of "primitive socialist accumulation" was over, and Russia had a thriving industrial economy. To maintain growth at the desired tempo, Stalin insisted on what he called a temporary "tribute" from the peasants in the form of food and agricultural raw materials. This tribute was incompatible with the maintenance of friendly relations with the peasantry. While searching for ways around this problem, Stalin came to a momentous decision: to impose a COLLECTIVE FARM structure on the peasantry before industrialization provided the necessary technical base for such a change in the

form of electrification and tractors.

Forced collectivization led to an upheaval in the age-old peasant way of life. The violent and hasty way collectivization was carried out magnified the costs of the process. In late 1929 Stalin decreed "the liquidation of the kulak as a class." Kulak was the Bolshevik term for the better-off peasant who had become the scapegoat for all difficulties. Millions of peasants were uprooted from their farms and deported to remote regions. The replacement of individual peasant farms with collective ones was done so rapidly that massive disorganization resulted. Despite temporary retreats, the process of collectivization was pushed on unrelentingly. The government's refusal to relax the pressure or even to admit the existence of a problem turned the harvest failure of 1933 into a famine in which millions perished.

Elimination of Dissent

Stalin was aware that these radical and costly policies were viewed with grave misgivings by many within the party. His fanatical insistence on party unity, coupled with his suspicious and resentful personality, led him to deal with real and suspected opposition by means of the GREAT PURGE, a campaign of terror that reached its climax in 1937-38. The decimation of the country's political and economic elite was only the tip of the iceberg. In the course of the purge millions of Soviet citizens were executed or sent to forced

ACADEMIC AMERICAN ENCYCLOPEDIA

UNION OF SOVIET SOCIALIST REPUBLICS

labor camps.

Insistence on unity and centralized control was not confined to the party. All manifestations of "nationalism"--which to Stalin meant any attempt to attain genuine administrative autonomy--were stamped out. Cultural life fell under the control of central organizations such as the Union of Writers; writers and artists were told that SOCIALIST REALISM was the only permissible style.

Stalin and his supporters justified the violence inherent in policies such as de-kulakization and the great purge by the

need for vigilance against malevolent and seemingly ubiquitous class enemies. The emphasis on vigilance meant a great increase in power for the secret police organization set up in the early days of the revolution to deal with sabotage and counterrevolution. Under various names this organization (see KGB) lasted through the entire history of the Soviet Union and indeed may have outlasted it. Owing to the extraordinary terror of the 1930s, the secret police became the administrators of a vast empire of forced labor camps in which millions worked under inhuman conditions. The Russian acronym for the Main Administration of Camps (GULAG) became known throughout the world because of the description by Aleksandr SOLZHENITSYN of the camp system in *The Gulag Archipelago* (1973).

THE FORMATION OF SOVIET FOREIGN POLICY

The counterpart of unity at home was the effort to sow disunity among the enemies of communism abroad. The Bolsheviks were extremely conscious of the weakness and vulnerability of the Soviet Union--a poor, devastated country surrounded by hostile capitalist states. If the enemies of the revolution had so far failed to crush it, it was only because they were preoccupied with their own conflicts. It was the job of Soviet foreign policy to use these conflicts to give the revolution a breathing space. The Soviet Union did not have the strength even to think of conquering; its motto had to be "divide and survive."

Withdrawal from the War

The first foreign policy act of the new Soviet government after the revolution in 1917 was an appeal to the toilers of the

UNION OF SOVIET SOCIALIST REPUBLICS

world to force their governments to conclude an immediate, equitable peace. When this met with no response, Lenin and his colleagues had to decide whether to continue the war with Germany. The disintegration of the army and the collapse of the economy left them even less able to conduct a successful war than previous Russian governments had been. On the other hand, the Germans demanded extremely harsh conditions and substantial territorial losses as the price for peace.

In early 1918, in the small border town of BREST-LITOVSK, the Bolsheviks signed a treaty accepting these conditions. Even after signing, Lenin had to use all his prestige to get the party to ratify the treaty. His sober assessment of Russian weakness was later regarded as his finest hour in foreign relations. The fledgling Soviet government obtained sufficient breathing space to survive until Germany itself was defeated by the other capitalist powers in November 1918. But the conclusion of a separate peace with Germany also provided the Allies, who regarded this as a betrayal, with an excuse to intervene against the Bolsheviks in the civil wars that followed. Their intervention was ineffective, partly because of rivalries among the Allies themselves.

International Recognition

When the civil wars drew to a close, these rivalries speeded up the process of opening trade relations and receiving diplomatic recognition. Germany, isolated after its defeat, was the first of the major powers to establish ties with the USSR (1922). Others followed, although the United States delayed recognition until 1934, the same year in which the USSR was admitted to the LEAGUE OF NATIONS.

Relations With Germany

The central foreign policy dilemma of the Soviet Union during the interwar years was how to respond to the rising power of Germany. This dilemma was an inheritance from the tsarist period, when the government had two options: be friendly to Germany in the hope that it would expand elsewhere, or join with Germany's enemies in the hope of preventing German expansion of any kind. In the end, the tsarist government had chosen the second option, which led to Russia's failure in World War I and the eventual collapse of tsarism itself.

ACADEMIC AMERICAN ENCYCLOPEDIA

UNION OF SOVIET SOCIALIST REPUBLICS

After the civil wars came to an end, the Soviet Union pursued the course of rapprochement with Germany. Since both Germany and Soviet Russia were regarded almost as pariahs in the international system, there was ground for common interest.

The Treaty of Rapallo (Apr. 16, 1922) formalized relations between the two countries and led to secret military collaboration. But the rise to power of Adolf HITLER in the early 1930s put an end to any further cooperation. Hitler's anticommunism and his open desire for expansion toward the east forced the Soviet Union to return to the second option of trying to isolate Germany.

Under the policy known as "collective security," the USSR tried to work together with France and Britain in order to convince Germany that expansion would not pay. Whatever chance existed of effective cooperation between the Soviet Union and the capitalist democracies ended in 1938 and 1939 with the MUNICH CONFERENCE and Hitler's takeover of Czechoslovakia. With Hitler's encouragement, Stalin rapidly switched course again and in August 1939 he signed a nonaggression treaty (the NAZI-SOVIET PACT) with Germany. Relieved of fear of a two-front war, Hitler promptly attacked western Poland (while the Soviets invaded eastern Poland), and World War II began. But if Stalin hoped for a long drawn-out war between Germany and the Western powers, he was soon disappointed. Hitler quickly dominated the European continent and turned his sights east. Neither of the two options for dealing with Germany--separate deal or collective security--seemed to work.

The Communist International

The ultimate removal of the threat from outside could happen only by means of a world socialist revolution, but after the early 1920s the Soviets did not expect this to occur in the foreseeable future. In the meantime, however, foreign Communist parties helped turn social conflict within capitalist countries to Soviet benefit. The Communist parties were united in the Communist International, or COMINTERN, founded by Lenin in 1919.

Although it would be unfair to reduce the significance of the Comintern simply to a tool of Soviet foreign policy, it remains true that the Bolshevik party easily dominated the Comintern because of its immense prestige and its material resources. The defense of the Soviet Union was enjoined upon all member

UNION OF SOVIET SOCIALIST REPUBLICS

parties as their primary duty. The existence of the Comintern gave the USSR a chance to practice some innovative dual-track diplomacy: one track at the level of relations between states, and the other at the level of relation between parties. It is unclear, however, whether the Soviets gained more from dual-track diplomacy than they lost from the irritation of capitalist democracies at Soviet propaganda and calls for revolution. The Comintern was disbanded in 1943 in deference to the wishes of Stalin's World War II allies.

In the period between 1939 and 1941 the Soviet Union incorporated eastern Poland, the Baltic countries (Latvia, Estonia, Lithuania), KARELIA, and BESSARABIA. Most of this new territory had earlier been part of the tsarist empire. The Soviets had long felt that the small nations on their western borders could easily be used as anti-Soviet tools by the capitalist powers. The POLISH-SOVIET WAR of 1920 had reinforced this feeling. The Nazi-Soviet Pact gave Stalin the opportunity to remove this source of danger, and the impending conflict with Germany provided a motive.

WORLD WAR II

In 1931, Stalin justified the high tempo of economic growth by saying "We are fifty or a hundred years behind the advanced countries. We must make good this distance in ten years. Either we do it, or they crush us." Exactly ten years later--22 months into WORLD WAR II--the Soviet Union was invaded by Nazi Germany. The crucial test of the Stalinist system had begun.

It did not begin auspiciously. When Hitler ordered his troops to cross the border on June 22, 1941, he achieved almost complete surprise. Stalin's intelligence failure was even more embarrassing than the case of Pearl Harbor later in the year, since land invasions should be harder to camouflage than air attacks. The German armies were able to cause enormous damage to the Soviet armed forces and to push deep into the country. Stalin's paranoia had led to decimation of the top ranks of the Red Army in 1937-38, and it took some time before effective leadership was restored to the Soviet armed forces.

On the domestic front, the war emergency put survival ahead of efficiency and brought out the advantages of the Soviet system: it was able to mobilize resources, impose strict priorities, and neutralize discontent. Massive relocation of factories and

ACADEMIC AMERICAN ENCYCLOPEDIA

UNION OF SOVIET SOCIALIST REPUBLICS

workers gave witness to a impressive ability to manage in the midst of chaos.

Now that both Great Britain and the USSR were at war with Germany, there was little barrier to a real alliance. The United States joined them when it was forced into the war later in 1941. Through programs such as LEND LEASE, the Western allies were able to give considerable material aid to the Soviets. The fight on the eastern front, where Hitler and Stalin met head-on, was many times more brutal and barbaric than in western Europe. The hostilities of the later cold war period allowed Americans to forget the huge sacrifices made by the Soviet Union in the fight against Hitler. During the war, the American mass media had a different attitude. In March 1943, Life magazine had a special issue on the USSR with a photograph of Stalin on the cover. One article described "Red leaders" as "tough, loyal, capable administrators." The Life editors commented, "It is safe to say that no nation in history has ever done so much so fast. If the Soviet leaders tell us that the control of information was necessary to get this job done, we can afford to take their word for it for the time being."

When the Germans failed to take Moscow in late 1941, they lost their chance for a quick end to the war. The turning point was the months-long battle at STALINGRAD, a city on the Volga named for Stalin because he had won a victory there during the civil wars. Between the middle of 1942 and early 1943, Hitler continued to throw away some of his best troops in an attempt to take the city. The surrender of the German army at Stalingrad in February 1943 was the beginning of the end of the Third Reich.

After that, although many bloody battles remained to be fought, the Red Army moved inexorably toward Berlin. In May 1945 the Soviet flag flew over the ruins of the German Reichstag building in the German capital, while American and Soviet armies met at the Elbe River. At the request of the United States and Great Britain, the Soviets also joined the war against Japan after the defeat of Germany. They had just enough time to fight some hard battles with the Japanese army before the dropping of the atom bombs on Hiroshima and Nagasaki led to Japan's surrender.

THE LAST YEARS OF STALIN'S RULE

ACADEMIC AMERICAN ENCYCLOPEDIA

UNION OF SOVIET SOCIALIST REPUBLICS

According to Stalin's official biography, the Great Patriotic War (the Soviet term for World War II) was "a stern test of all the material and moral forces of the Soviet state, a test of its stability and vitality. The Soviet socialist state emerged with credit from the test of war, stronger and more stable than ever." Stalin felt that his policies of rapid industrialization, collectivization, and vigilance had been vindicated: the Germany that had defeated tsarist Russia had been destroyed by Soviet Russia. For as long as the Soviet Union lasted, its basic legitimacy in the eyes of its own citizens derived in large part from the victory over Germany.

For a brief moment in 1945, it seemed to many people that the era of suspicion and repression would soon end, and that the system was secure enough to open up at home and abroad. These hopes were soon dashed: the party leadership felt the need to clamp down hard for the sake of economic reconstruction and national security. The devastation caused by the war and the unrelenting pressure from the state made the second half of the 1940s one of the most difficult periods for ordinary people.

Postwar Domestic Repression

Soviet intellectual and cultural life reached its lowest point at this time. One of Stalin's lieutenants, Andrei Zhdanov, gave his name to an era by denouncing two of the country's finest literary artists, the short-story writer Mikhail Zoshchenko and the poet Anna AKHMATOVA, whose work was judged deficient according to official party norms. The scandal in science was perhaps even worse. A charlatan named Trofim LYSENKO managed to convince top leaders that he could perform agricultural miracles--if only the laws of genetics were denied. Genetics was termed a bourgeois pseudo-science, and an entire branch of biology was destroyed in the Soviet Union. A few geneticists managed to keep working while camouflaged by their fellow scientists as physicists--an example of the methods needed to keep intellectual culture alive during the Stalin years.

According to Stalin, the war showed that national diversity in the Soviet Union was no longer the source of weakness that it had been for tsarism. Yet his own suspicious vindictiveness

was revealed nowhere more clearly than in relations with the national minorities. Toward the end of the war, Stalin decided that some Soviet nationalities had collaborated with the

Germans, and so he simply deported whole nations such as the Crimean Tatars (see TATAR) out of their homelands to other parts of the USSR. Chauvinistic propaganda extolling the Russian people became ubiquitous; scarcely-veiled anti-Semitism became more and more noticeable in press campaigns. Winston Churchill's phrase the IRON CURTAIN was an appropriate one to describe Stalin's policy of cutting the USSR and its satellites off from the rest of the world.

ACADEMIC AMERICAN ENCYCLOPEDIA

UNION OF SOVIET SOCIALIST REPUBLICS

the Soviet Union was no longer the source of weakness that it had been for tsarism. Yet his own suspicious vindictiveness was revealed nowhere more clearly than in relations with the national minorities. Toward the end of the war, Stalin decided that some Soviet nationalities had collaborated with the Germans, and so he simply deported whole nations such as the Crimean Tatars (see TATAR) out of their homelands to other parts of the USSR. Chauvinistic propaganda extolling the Russian people became ubiquitous; scarcely-veiled anti-Semitism became more and more noticeable in press campaigns. Winston Churchill's phrase the IRON CURTAIN was an appropriate one to describe Stalin's policy of cutting the USSR and its satellites off from the rest of the world.

Soviet Policy in Eastern Europe

After the sufferings of the war, the Soviets felt justified in insisting on friendly governments in Eastern Europe. In practice, this meant installing Soviet-style regimes in all the Eastern European countries under Red Army control (with the exception of Austria). By 1948, diversity in Eastern Europe had been replaced by uniformity and complete Soviet control. The only exception was Yugoslavia, which was also the only country where a Communist party had come to power without the direct help of the Red Army. Tito, the leader of the Yugoslav Communists, successfully defied Stalin and asserted his independence.

The capitalist encirclement of earlier years had now been replaced by a socialist encirclement protecting the Soviet Union's western borders. Many Soviet citizens regarded this as Stalin's greatest foreign policy achievement. Nevertheless, a high price had to be paid: the Soviet leadership never solved the dilemma of establishing governments that were both loyal to

the USSR and acceptable to the local populations.

The issue of the Katyn Forest massacre is an example of the insuperable difficulties faced by the Soviets in dealing with their Eastern European satellites. Some time after the invasion of eastern Poland in 1939, Soviet police had executed about 10,000 captured Polish officers in the Katyn Forest near Smolensk. The German Nazis discovered the bodies in a mass grave, but the Soviet Union never admitted the crime. After the war, Polish citizens were determined to discuss the issue, and the Soviet leadership was just as determined to prevent

UNION OF SOVIET SOCIALIST REPUBLICS

discussion. This made it impossible for any Polish government to please both the Soviet Union and their own people. The USSR only admitted responsibility for Stalin's crime in the late 1980s when Communism in Eastern Europe was already doomed.

Soviet domination of Eastern Europe was also a major factor in the COLD WAR that developed between the USSR and the West during the late 1940s. The memory of the World War II alliance quickly faded away, to be replaced by Western fears of Soviet expansionism and its implied threat to Western Europe. Chronic restlessness in the Eastern European satellites regularly provoked repressive Soviet interventions that confirmed Western mistrust.

Stalin's Death

The image of advancing world communism seemed to be vindicated in the late 1940s and early 1950s by the explosion of Soviet atomic and hydrogen bombs, the establishment of a Communist government in China, and the invasion of South Korea by Communist North Korea. Yet there is evidence that Stalin retained to the end a basic feeling of vulnerability in relation to the advanced capitalist powers.

In the last years of his life the negative aspects of Stalin's character became even more pronounced. The "cult of personality" glorifying the Soviet leader, which had begun in earnest in the late 1930s, reached new heights in the postwar years. Stalin was continually praised as the father of peoples, the wise teacher of mankind, and the greatest genius

of all times and places. In a final outburst of paranoia, he became convinced that his own doctors (who were mainly Jewish) were plotting to poison him (an episode known as the Doctors' Plot). Luckily for these doctors and probably for many of the political leaders close to him, Stalin died suddenly in March 1953.

THE SECOND INTERNAL CRISIS OF THE SOVIET SYSTEM

Stalin's death created a new set of opportunities and risks for the Soviet leaders. Their immediate task was de-Stalinization: ridding the system of the excesses associated directly with the personal tyranny of Stalin. But de-Stalinization was only the negative side of the wider task of creating a self-sustaining system that could hold its own in global competition. In

UNION OF SOVIET SOCIALIST REPUBLICS

response to the first internal crisis of communism in the mid-1920s, Stalin had staked everything on creating an industrial base for Soviet society. The second internal crisis posed the challenge, not only of repudiating Stalin's crimes, but of cashing in on his achievements.

In the economic sphere, the system created during the Stalin years emphasized mobilization and central control rather than efficiency and consumer sovereignty. The logic of the Soviet system was extensive (growth results from bringing in new resources) rather than intensive (growth results from more productive use of existing resources). The extensive system works best when national priorities are clear and unambiguous and when vast reserves of raw materials allow great inefficiencies to be tolerated. Such was the case during the Stalin years when the country was either preparing for war, fighting a war, or repairing the damage done by war. But the extensive system could not meet the challenges of a postwar world in which raw materials become scarcer even in the resource-rich USSR, and when the satisfaction of consumer needs called for flexible efficiency.

Stalin bequeathed to the country the industrial and technological base needed to create a formidable arsenal of nuclear weapons and a prestigious space program. This assured the USSR's status as a global superpower, but in the long run

global competition required an economic and cultural vitality that the Soviet system simply did not possess. In the political sphere, the Soviet rulers faced a familiar dilemma: if they allowed people to press their claims freely and to express their grievances, the system might not be able to handle the result. If they did not allow public discussion of social problems, not only would many problems go unresolved, but the inner alienation of Soviet citizens would continue to grow. This basic dilemma was made even sharper by the existence of national minorities at very different levels of social development.

THE KHRUSHCHEV PERIOD

De-Stalinization began as soon as Stalin breathed his last. The first sign was the announcement that the Doctor's Plot had been a frame-up. In June 1953 came the arrest of Lavrenti BERIA, the secret police chief who had been as much feared by the political elite as he was by ordinary citizens. Beria was

UNION OF SOVIET SOCIALIST REPUBLICS

tried in secret and executed.

The Denunciation of Stalin

De-Stalinization had explosive potential for the struggles within the Soviet leadership, because all the top leaders had been deeply implicated in Stalin's crimes. The person to use the weapon of de-Stalinization most skillfully was Nikita S. KHRUSHCHEV, the new secretary of the party. Combining a personal hatred of Stalin with a bold sense of political tactics, Khrushchev denounced Stalin as a tyrannical criminal in a closed speech at the 20th Party Congress in 1956. This so-called Secret Speech quickly became known throughout the world and marked a turning-point in the world Communist movement. Matching deeds to words, Khrushchev was also responsible for the liberation of millions of prisoners from the swollen labor-camp system. The return of so many victims of Stalin's terror permanently changed Soviet society.

One of these returnees was Aleksandr Solzhenitsyn, who in 1962 sought to publish his novel ONE DAY IN THE LIFE OF IVAN DENISOVICH, a short, understated, and moving description of an

ordinary worker serving time in a forced labor camp. Owing to Khrushchev's support, Solzhenitsyn's book was published. But because of the dilemmas described earlier, Khrushchev's attitude toward de-Stalinization and cultural freedom in general was erratic and inconsistent. When the novel DOCTOR ZHIVAGO by the Soviet poet Boris PASTERNAK was published abroad and earned Pasternak a Nobel Prize (1958), the Soviet government reacted with fury and incomprehension. A press campaign was mounted against Pasternak, who was forced to renounce the Nobel Prize; this despite the fact that Pasternak's book was in many ways less "anti-Soviet" than Solzhenitsyn's.

Foreign Affairs

The same erratic character marked Khrushchev's foreign policy. One memorable image of Khrushchev shows him banging his shoe angrily in the United Nations and promising to bury capitalism; another shows him standing in an Iowa cornfield eagerly learning about the latest U.S. agricultural techniques. Khrushchev preached nuclear disarmament and at the same time made crude threats about "turning out rockets like sausages." Under Khrushchev, the Soviet Union played an active role in the

ACADEMIC AMERICAN ENCYCLOPEDIA

UNION OF SOVIET SOCIALIST REPUBLICS

THIRD WORLD for the first time. Khrushchev was genuinely confident that socialism was the wave of the future, and the anti-Western policies of many newly independent colonial countries seemed to confirm his outlook. In the long run, however, it is far from clear who was using whom. The Third World leaders may have been manipulated by the Soviets, but they also manipulated the Soviet Union as a counterweight against the West. The USSR, for its part, found itself locked in a global competition it could not sustain. Khrushchev's support for the Castro regime in Cuba led to the CUBAN MISSILE CRISIS (1962), a confrontation with the United States in which the Soviets were forced to back down.

Domestic Policies

At home, Khrushchev's policies were characterized more by a search for a quick fix than by systematic reform. One of his major projects was the Virgin Lands campaign, which brought

under cultivation substantial reserves of agricultural land in Kazakhstan, western Siberia, and the southern Urals. Begun in 1953, its aim was to increase grain production. Khrushchev did obtain successful results during the first few years, but the sequel showed the tragic limitations of the system. The land was overworked, erosion spread swiftly, and nervous local officials hid the magnitude of the disaster from the government in Moscow. By the early 1960s, much of the Virgin Lands area had become a dustbowl.

Khrushchev's experiments did not endear him to the party elite. In 1963, for example, Khrushchev split the party in two, giving one half responsibility for industry and the other half responsibility for agriculture. The confusion engendered by this and similar schemes created support for his removal, which took place in October 1964 as the result of a widespread conspiracy among party leaders. Khrushchev's defeat was also a moment of victory for some of his basic principles: he was not executed, tried, or expelled from the party, but simply put on pension and kept from public notice. He contrived to use his time to write memoirs, which were smuggled abroad and published before his death in 1971.

BREZHNEV AND THE ERA OF STAGNATION

The party oligarchy that dismissed Khrushchev replaced him with Leonid BREZHNEV. Brezhnev is said to have been chosen as a compromise candidate who got along with people and whose main

ACADEMIC AMERICAN ENCYCLOPEDIA

UNION OF SOVIET SOCIALIST REPUBLICS

passions were dominoes and hunting. But he showed unexpected political skills, and by the mid-1970s his opponents had been unceremoniously removed from the top elite and a mini-Brezhnev personality cult was in full swing.

Rationalization

Brezhnev's main response to the post-Stalin crisis of communism was an attempt at professionalization and rationalization. Through increased reliance on expertise, careful discussion of government policies, streamlining of bureaucratic structures, and patient long-term strategies, the Brezhnev leadership hoped to bring the country into the second half of the 20th century. A symbol of the attempt to renounce the irrationalities of the

past was the final downfall of Lysenko, whose greatest triumph had been under Stalin, but who had also fooled Khrushchev with promises of an agricultural quick fix.

But those who hoped for Khrushchevism without Khrushchev--for continued liberalization without erratic leadership--were soon disappointed. The flip side of rationalization was an abhorrence of unpredictability and instability that made the Brezhnev leadership very suspicious of any reform initiative from below. This became crystal clear in 1968, when the reform movement initiated by the Communist party in Czechoslovakia (the Prague Spring) was crushed by Soviet tanks. This was accompanied by an enunciation of what the West came to call the Brezhnev doctrine: the Soviet Union claimed a right to intervene in other countries if the basic principles of socialism were threatened.

The 1966 trial of Andrei SINYAVSKY and Yuri Daniel also made it clear that liberalization reforms would be halted. The crime of these two fiction writers was to send works to be published abroad. But the Brezhnev leadership was determined bring an element of predictability even to repression: the ordinary citizen who had not broken the rules did not have to feel threatened with arrest.

Detente

The combination of rationalization and control also characterized Brezhnev's policy of DETENTE. Brezhnev's aims were to regularize relations with the United States and to obtain needed economic benefits from world trade, but not open

ACADEMIC AMERICAN ENCYCLOPEDIA

UNION OF SOVIET SOCIALIST REPUBLICS

up Soviet society so much that there was a risk of losing social or economic control. Despite a flurry of summit meetings with U. S. Presidents Nixon, Ford, and Carter, Brezhnev carried on the competition with the West in the Third World begun by Khrushchev. Soviet activities in the developing countries provoked great concern in the United States, but from today's perspective what stands out is the Soviet Union's increasing marginalization in global economic and political structures.

Political Paralysis

Brezhnev's attempts at rationalization could not compensate for the lack of any source of self-sustaining dynamic within the decaying Stalinist system. During the second half of the Brezhnev era, this became evident in a growing political paralysis at the top. Brezhnev himself never fully recovered from strokes he suffered in the late 1970s. From then on his leadership became less and less effective. Under the slogan "trust in cadres," there was very little personnel renewal at top levels. The political system seemed to be on autopilot.

The Dissident Movement

The growing stagnation in state and party was not matched by stagnation in society. On the contrary, partly in response to official paralysis, Soviet citizens exhibited great energy in pursuing their own goals. One manifestation of this autonomous activity was the dissident movement, which braved persecution in order to advance critiques of the system, discuss reform ideas, and publicize abuses. Dissident writings were circulated by means of SAMIZDAT (self-publishing): manuscripts were passed around from hand to hand or painstakingly copied on home typewriters. Similar energy was shown by black marketeers and other participants in a burgeoning underground economy.

Brezhnev's Last Years

Stagnation was also evident in foreign policy; the Soviet government seemed unable to change even clearly unproductive policies. The continued placement of nuclear-armed missiles in the western Soviet Union undid previous efforts to reassure western Europe. The quarrel with Communist China that had begun under Khrushchev escalated to serious armed clashes along the border. A final, disastrous decision was made in the

ACADEMIC AMERICAN ENCYCLOPEDIA

UNION OF SOVIET SOCIALIST REPUBLICS

twilight of the Brezhnev era: in late 1979, Soviet troops intervened in Afghanistan and quickly became bogged down in a long drawn-out war that was extremely costly both economically and politically.

By the early 1980s, long inattention to basic problems was

deepening into a general crisis of the whole system. Economic growth had slowed almost to a standstill. Even more ominous was a growing social--indeed, spiritual--crisis. Soviet society seemed cut off from both its past and its future. Unable to face the risks of a genuine discussion of the past, the Soviet government neither criticized Stalin nor defended him--it simply did not mention him. The old dreams of bolshevism had faded away, and the only substitute Soviet leaders could find was a nationalism that emphasized Russia and alienated the ethnic minorities. Without great hopes for either a national or a personal future, people withdrew into private concerns.

When Brezhnev finally died in late 1982, there was a widespread feeling that radical reforms were necessary. The next two party leaders--Yuri ANDROPOV and Konstantin CHERNENKO--only lasted about a year each. Not until spring 1985 was the fate of the party and the country put into the hands of a young and dynamic leader with a strong reform agenda: Mikhail GORBACHEV. GORBACHEV AND THE FINAL INTERNAL CRISIS OF THE USSR

Gorbachev's prescription for the ills of the Soviet system was what he called PERESTROIKA (restructuring). The perestroika program was based on a now-or-never feeling that time was running out for the Soviet Union: it either had to make good on the promises of socialism or sink into the status of a disregarded third-class power. Perestroika's most dramatic component was glasnost (openness). Glasnost is related to the Russian word for voice, and indeed the aim of glasnost was to give Soviet society back its voice--in the expectation of hearing constructive criticism. Gorbachev's economic aims were less bold: they combined elements of Brezhnev-style rationalization with innovative elements such as the legalization of cooperatives, which in essence were small private businesses.

In politics, Gorbachev wanted a shift of emphasis from party to state--that is, a shift from a monopoly of power by an unelected vanguard party to legislative accountability and the

▲PRODIGY(R) interactive personal service 06/25/93 11:48 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

UNION OF SOVIET SOCIALIST REPUBLICS

rule of law. In foreign policy, he and his foreign minister Eduard SHEVARDNADZE became global spokesmen for "new thinking"

that stressed interdependence and cooperation rather than confrontation. Gorbachev's ambitious restructuring was portrayed not as a repudiation of the system but as a radical de-Stalinization that would keep faith with Leninist ideals betrayed by Stalin.

The Progress of Perestroika

When Gorbachev set forth the outlines of this highly ambitious program, the first reaction, at home and abroad, was doubt that he was really serious. The signs in the first year or so were not completely clear. In April 1986 the nuclear disaster at CHERNOBYL was compounded by secrecy and feeble attempts at a coverup. The honor of glasnost was reclaimed, however, when Gorbachev used Chernobyl as a symbol of the sins of the old order and insisted on a policy of (almost) full disclosure. At the end of 1986 Gorbachev released Andrei SAKHAROV from his internal exile in the Volga city of Gorky (Nizhny Novgorod). Sakharov was a brilliant scientist who had become a dissident and a fearless protector of human rights during the Brezhnev era. In its usual less than wholehearted way, the Brezhnev leadership had silenced him at the time of the Afghanistan invasion by exiling him to the closed city of Gorky without right of communication.

Continued predictions in the West that perestroika was slowing down seemed confirmed in the fall of 1987 when the most outspoken defender of radical reform, Boris YELTSIN, was dropped from the top leadership amidst a chorus of old-style political abuse. But by 1988, there was no mistaking the reality of Gorbachev's reforms. Glasnost went ahead at full speed, revealing not only the crimes of the Stalin era but the full horrifying dimensions of the contemporary crisis. Gorbachev moved on with plans to create a genuinely effective national legislature. The new rules of political life were startlingly demonstrated when Yeltsin returned from disgrace and was elected to the legislature despite (or rather because of) the opposition of the party establishment. Sakharov and many other outspoken critics were also elected.

In foreign affairs, not only was there great progress on arms control, but Soviet troops were withdrawn from Afghanistan. Most spectacular of all, in 1989 Gorbachev allowed Soviet

UNION OF SOVIET SOCIALIST REPUBLICS

control over Eastern Europe to evaporate, as Communism was overthrown and independent governments were established in one satellite country after another.

The Breakup of the USSR

The only ominous note was that the economic reform seemed stalled and economic performance had begun a long downslide. By 1990 there were other growing signs of loss of control. Early in 1990 the Communist party's official monopoly of power was ended. While this move was hailed as a major step toward political pluralism, there was no political force ready to replace the party as a unifying element. In March 1990 Lithuania declared independence. Perhaps more significant than this bold move by the tiny Baltic republic was the reactivation of long-dormant feelings of independence in the Russian Federation and Ukraine. Yeltsin's election (June 1990) as president of the Russian Federation made him the main opponent of central power. Gorbachev became obsessed with preserving the union and suspicious of radical democrats who seemed to look forward to its disintegration. By the end of 1990 his shift to the right was pronounced enough to provoke Shevardnadze to resign as foreign minister while warning of a possible dictatorship.

In spring 1991 Gorbachev changed course as he came to realize that his only chance to preserve the union was to work with the leaders of the republics and not against them. For many loyal members of the party and the security forces, as well as managers of industry and collective farms, the country as they had known it was on the point of falling apart. The last stand of the old guard was an attempted coup in August 1991. It was easy for the plotters to take over the central government, but they found it impossible to topple Yeltsin and the Russian Federation government. The coup collapsed within days, and the Communist party was outlawed.

The fate of the August coup showed how little vitality was left in the Soviet Union's central government, and it was not long before appropriate conclusions were drawn. In another, quieter coup in December, the leaders of Russia, Ukraine, and Belarus declared that a COMMONWEALTH OF INDEPENDENT STATES would replace the Union of Soviet Socialist Republics. This declaration only ratified the reality of republican independence. Gorbachev bowed to the inevitable and resigned

ACADEMIC AMERICAN ENCYCLOPEDIA

UNION OF SOVIET SOCIALIST REPUBLICS

at the end of the year. The 74-year old history of the Soviet Union had come to an end.

Evaluation of Gorbachev

Gorbachev was admired in the West as the man who ended the cold war, for which he received the Nobel Peace Prize in 1990. At home he became highly unpopular as the dream of reform turned into the reality of collapse. Two somewhat contradictory criticisms of his leadership were heard in the Soviet Union. One blamed him for reforms that were half-hearted and tied to the discredited ideals of communism, further claiming that he woke up too late to the problems of the nationalities, and that his commitment to a central union led him to sully his name with ineffective repressive measures. According to the other criticism, Gorbachev went too far too fast: he destroyed the effectiveness of coordinating mechanisms such as the central planning organs and the party without putting anything in their place. The fact is that Gorbachev started a process of renewal that he could not control. Probably no one else could have done much better, given the inner contradictions of communism.

SOVIET INSTITUTIONS AND CULTURAL LIFE

The central fact of Soviet political life was what the Soviet constitution called "the party's role as leader." In practice, this meant that the Communist party made the basic decisions and intervened in day-to-day government activities to the extent necessary to carry them out. The CPSU itself was an unelected body that chose new members according to its own standards. During the Brezhnev era it was a fairly faithful reflection of the country's elite. Theoretically the internal life of the party was controlled by the membership as a whole, which elected delegates to party congresses every five years or so. In reality the party was highly centralized, and elections of party officials merely ratified appointments from above.

The Structure of the CPSU

The Soviet Communist party consisted of three levels that were separate from each other in many ways. At the top was the POLITBURO, a body of 10 to 20 people theoretically elected by the party congress. Since Stalin's day the de facto leader of the politburo was the general secretary, who was also responsible for the work of the secretariat, an organization

that might be regarded was the party's top civil service. The

ACADEMIC AMERICAN ENCYCLOPEDIA

UNION OF SOVIET SOCIALIST REPUBLICS

politburo reported regularly to the central committee, a large body with several hundred members. The only time the central committee had decisive influence was if there was a serious split in the politburo oligarchy.

The central committee also had importance because it represented the second level of the party: the regional first secretaries and the local party bureaucrats (often called apparatchiki). These local party officials were responsible for the overall performance of the regions entrusted to them. Both Gorbachev and Yeltsin were local party bosses before moving on to the national level. Yeltsin's memoir *Against the Grain* (1990) contains a revealing picture of the life of a regional secretary during the Brezhnev era.

At the lowest level was the rank-and-file membership of the party. Members were expected to help carry out party directives, but they had little influence over decision-making. In fact, although party membership was necessary for any ambitious career, it did not otherwise confer much power or privilege.

In form, the party could be compared to a parliamentary system. The regular members were the electorate, the central committee was the legislature, the politburo was the cabinet, the secretariat was the civil service, and the general secretary was the prime minister. The only difference was that power and authority flowed from the top down, not from the bottom up. But the comparison is revealing, because it shows that in the Soviet Union the party was the political substance and the state was only a shadow. There were elected bodies at all levels of the state, culminating in a supreme soviet (parliament) at the top. (The word SOVIET means "council" and referred originally to class-based self-governing committees created by workers during the Russian Revolution.) Nominations, however, were controlled by the party, and since only one candidate was nominated for each post, the elections were almost meaningless.

State Services and Controls

If the Soviet state was thus much weaker than its counterparts in western countries, it was in other ways much stronger, since it ran the entire economy. Each industry was controlled by an economic ministry that can be thought of as a huge monopolistic

ACADEMIC AMERICAN ENCYCLOPEDIA

UNION OF SOVIET SOCIALIST REPUBLICS

corporation with its headquarters in Moscow. The council of ministers that was supposed to coordinate their activities was equivalent to a huge gathering of the country's CEOs.

The day-to-day job of economic coordination was entrusted to state planning organs. Control by planners had severe limits, however, mainly because of the difficulty they had in obtaining reliable information. Economic outcomes were the result of complex negotiations between local managers and the center. Paradoxically, the commitment to central planning led to a large amount of unpredictability at all levels. Although the system was often called a "command economy," it was firmly based on material incentives, such as bonuses for plan fulfillment.

Central control went far beyond the economy. One tool of control were security forces that were used not only to punish dissidents but to preserve the country from outside influence. The media was also strictly censored, and nothing could be published without the party's approval.

The state also controlled education and health care. A comprehensive system of free primary, secondary, and higher public education succeeded in virtually eliminating illiteracy in the USSR by the 1960s. Health care was also free and available to all. In line with official Marxist ideology, a systematic effort was made to eliminate the influence of religion in Soviet society.

The insistence on central control was the major reason why Soviet official art generally enjoyed little prestige outside the USSR. Immediately after the revolution there was considerable ferment in literature, theater, and other areas, but to a large extent this was a continuation of a creative explosion that had begun in the decade before the revolution. After this burst of energy calmed down, there was little to

replace it. One area in which official art of the Stalin area did have world influence was music: works by Sergei PROKOFIEV and Dmitry SHOSTAKOVICH have found a permanent place in western symphonic repertoires.

Prospects for the Future

Many of the dilemmas that defeated Communism will remain alive in other forms to plague the successor states of the USSR. It

UNION OF SOVIET SOCIALIST REPUBLICS

will not be easy for these new nations to find a stable way of living together now that the heavy hand of the Kremlin has been removed. Russia will no doubt discover that the market system as a road to national greatness also has many potholes and unexpected detours. The task of creating responsive and responsible political structures will be complicated by an ongoing economic and social crisis.

Communism was a great glacier that locked up human energies for generations. Now that it is melting, many catastrophes are inevitable. But there is also a new chance to create a livable environment. To make good on that chance is a challenge not only for the peoples of the former Soviet Union, but for the whole world.

ACADEMIC AMERICAN ENCYCLOPEDIA

RUSSIA, HISTORY OF

European Russia was occupied by Indo-European and Ural-Altaic peoples from about the 2d millennium BC. Among the peoples present in the steppe north of the Black Sea were the CIMMERIANS. They were conquered by the SCYTHIANS in the 7th century BC. The Scythians in turn were largely displaced by the SARMATIANS in the 3d century BC. In the early centuries AD a succession of tribes, the GOTHs, the HUNS, and the AVARS, ruled the area. The KHAZARS (7th century) and the Bulgars (8th century) established substantial states. Slavic settlements in the area are documented from the 6th century on.

MEDIEVAL RUSSIA

The SLAVS probably came from southern Poland and the Baltic shore and settled in the region of mixed forest and meadowlands north of the fertile but unprotected steppe lands of the south. The Slavs engaged in agriculture, hunting, and fishing and gathered products of the forest. They settled beside the rivers and lakes along the water route that was used by VIKING warrior-traders (the Varangians) to reach Constantinople. Using their superior military and organizational skills, the Varangians exacted tribute from the Slavs and to this end consolidated their rule in key points on the route to Constantinople. About 862 a group of Varangians led by RURIK

took control of NOVGOROD. From there Rurik moved south and established (879) his authority in KIEV, strategically located above the Dnepr rapids where the open steppe met with the belt of Slavic settlements in the forest-meadow region.

Kievan Rus'

Under Rurik's successor, Oleg (d. c.912), Kiev became the center of a federation of strong points controlled by Varangian "dukes" who soon became Slavized in language and culture. Attempts by Duke SVYATOSLAV I (r. 945-72) to create an "empire" in the region between the Dnepr and Danube failed, but Kiev was effectively protected from nomads in the east by the Khazar state on the Volga. With the conversion (c.988) of Duke VLADIMIR I to Eastern Christianity, Kiev developed into a major cultural center, with splendid architecture, richly adorned churches, and monasteries that spread Byzantine civilization.

The political and cultural apogee of Kievan Rus' was reached under YAROSLAV the Wise, who ruled from 1019 to 1054. Politically, Kiev was the center of a federation of

ACADEMIC AMERICAN ENCYCLOPEDIA

RUSSIA, HISTORY OF

principalities tied together by their rulers who claimed to be descendants of Rurik. The unity of Kievan Rus' was more of an ideal than a reality (many internal feuds existed), but it served as an inspiration to later generations. The socioeconomic base of this polity has been a subject of controversy; liberal historians have singled out the trading role of the princes and their retinues (druzhina), whereas Soviets historians insisted on the primacy of agriculture and artisanal production. Probably trade was the mainstay of political power, and agriculture (complemented by hunting and fishing) was the major occupation of the population.

Culturally, Kiev served as the agent of transmission for Byzantine civilization--Orthodox Christianity and its art (music, architecture, and mosaics); it also developed, however, into the creative center of a high-level indigenous culture represented, in literature, by the sermons of Hilarion (d. after 1055) and Vladimir Monomakh (d. 1125); in historiography, by the early-12th-century Primary Chronicle; in law, by Yaroslav's codification, Pravda; and in monastic

life, by Kiev's 11th-century cave monastery (Lavra). This culture served as the common foundation for the later Ukrainian, Belorussian, and Great Russian civilizations.

The decline of Kievan Rus' (starting in the late 11th century) was brought about by internecine feuds, by a change in Byzantine trade patterns--which made the old river route obsolete--and by the depopulation resulting from slaughter by nomadic invaders from the east. The end, however, came swiftly when the MONGOLS, surging forth from Central Asia, overran the South Russian plain. Kiev was sacked in 1240, and the Mongol khans of the GOLDEN HORDE at Sarai on the Volga established their control over most of European Russia for about two centuries.

Mongol Rule

The overlordship of the Mongols (see also TATAR) proved costly in economic terms, because the initial conquest and subsequent raids to maintain the Russians in obedience were destructive of urban life and severely depleted the population. Equally costly--even to cities that escaped conquest, such as Novgorod--were the tribute payments in silver. Politically the yoke was not burdensome, for the Mongols ruled indirectly through local princes, and the church was even shown respect

RUSSIA, HISTORY OF

and exempted from tribute (enabling it to assume a cultural and national leadership role). The most deleterious long-lasting effect of Mongol rule was isolation from Byzantium and western Europe, which led to a turning inward that produced an aggressive inferiority complex. The exceptions were the free cities of Novgorod and PSKOV, ruled by oligarchies of merchants (the princes, such as ALEXANDER NEVSKY, were merely hired military leaders) in active contact with the HANSEATIC LEAGUE.

Rise of Moscow

In the shadow of Mongol overlordship and in the harsh environment of central Russia, to which the population had fled from the south, the society and polity of MOSCOW, or Muscovy, developed. Members of the ruling family of Kievan Rus' had seized free lands in the northeast and colonized them with

peasants to whom they offered protection in return for payments in money and kind. Each one of these princes was full master of his domain, which he administered and defended with the help of his retainers (BOYARS). A semblance of family unity was maintained by the claim of common descent from Rurik and of a "national" consciousness based on the Kievan cultural heritage. Taking advantage of genealogy, Mongol favor, church support, geographic situation, and wealth, some of the local princes--for example, those of VLADIMIR, YAROSLAVL, Moscow, Suzdal, and Tver--became dominant in their region and gradually forced the weaker rulers (along with their boyars) into their own service. Of these principalities Moscow gradually emerged as the most powerful. Its ruler Ivan I (Ivan Kalita; r. 1328-41) was granted the title grand duke of Vladimir by the khanate as well as the right to collect tribute for the Mongols from neighboring principalities. His grandson DIMITRY DONSKOI won the first major Russian victory over the Mongols at Kulikovo (1380). Finally, after victory in a fierce civil war, the elimination of a main rival at Tver (1485), and the winning over of most small independent princes, IVAN III, grand duke of Moscow (r. 1462-1505), emerged as the sole ruler in central Russia. The Golden Horde had regained control after Kulikovo, but a century later it was seriously weakened by internal strife. In 1480, therefore, Ivan III successfully challenged Mongol overlordship by refusing the tribute.

Moscow's triumph was not complete, however, because another putative heir to Kiev remained--the Grand Duchy of Lithuania, to whose rule many of the independent princes of the southwest

RUSSIA, HISTORY OF

and the large boyar retainers of Belorussia had gravitated. To the south and east the Muslim successors of the Golden Horde, the khanates of Kazan, Astrakhan, and the Crimea, were serious threats to Muscovy's security.

Although Moscow's annexation of Novgorod (1478) and Pskov (1510) gave it access to the profitable Baltic trade and control over the far-flung colonial lands of the northeast, it also opened the gates to religious and cultural challenges to the spiritual and artistic self-sufficiency and provincialism of central Russia. A conflict arose between church and state as well as between cultural nativism and innovation; it ended,

in the second quarter of the 16th century, in a compromise that reaffirmed and strengthened the political values of Moscow (autocracy) while respecting the economic power and position of the church and liberalizing its cultural life to admit the influences from the Balkans and western Europe. Yet the strain between those who wanted a spiritualistic church, divested of worldly wealth (the nonpossessors, or Volga Elders), and the possessors, followers of Joseph of Volokolamsk (d. 1515), who wished to retain the church's wealth and institutional power, continued to affect Muscovite cultural life.

Organization of the Muscovite State

The main political task of the grand dukes of Moscow was the absorption of formerly independent princes and their servitors into the service hierarchy of Moscow. This absorption was achieved by expanding the membership of the boyar council (duma) to include the newcomers. A system of precedence (mestnichestvo) based on both family status and service position kept the boyar class divided. In addition, from the late 15th century on, the grand duke created a class of military servitors (dvorianstvo) entirely subordinated to him by grants of land on a temporary basis, subject to performance of service. The peasantry remained outside this system, with village communes taking care of local fiscal and police matters. Towns were under the direct rule of the grand duke's representatives and enjoyed no municipal freedoms.

The culmination of absolutism was dramatically symbolized by the grandson of Ivan III, IVAN IV (r. 1533-84). Assuming (1547) the title of tsar, he underlined his claim to the succession of both Byzantium and the Golden Horde. The conquests of the khanates of Kazan (1552) and Astrakhan (1556)

RUSSIA, HISTORY OF

followed, putting the entire course of the Volga under Russian control. These conquests initiated further expansion (1581) into Siberia, whose western regions were conquered by the Cossack leader YERMAK TIMOFEYEVICH, sponsored by the Novgorod family of salt merchants, the Stroganovs.

Relying on his absolute power and increased military potential, Ivan IV attempted to eliminate the competition of Lithuania and

gain a port on the Baltic. The 25-year war (1558-83) against Poland-Lithuania, Livonia, and Sweden--accompanied by several devastating raids of Crimean Tatars against Moscow (for example, in 1571)--ended in failure and seriously debilitated the country. To mobilize all resources and cope with internal opposition, Ivan IV set up his own personal guard and territorial administration (oprichnina, 1565-72), whose exactions and oppression did great damage to both the economy and the social stability of the realm. The combined needs of the military servitor class for labor and of the government for tax-paying peasants led to legislation limiting the mobility of peasants. The edicts of Ivan's successors (Fyodor I, r. 1584-98, and BORIS GODUNOV, r. 1598-1605) initiated a process that culminated in the complete enserfment of the Russian peasantry (Code of 1649).

THE 17TH AND 18TH CENTURIES

The Muscovite dynasty ended in 1598 with the death of Ivan IV's son Fyodor I. Real power during Fyodor's reign had been exercised by his brother-in-law Boris Godunov, who was chosen to succeed him. Although Boris was a strong ruler, he was regarded by many as a usurper. The exhausted country was, therefore, precipitated into turmoil marked by the appearance of a series of pretenders to the throne and provoking invasions by Poland, Sweden, and the Crimean Tatars (see TIME OF TROUBLES; 1598-1613). Disgruntled boyar families, enserfed peasants, COSSACKS, and lower clergy tried in turn to take advantage of the anarchy, but none succeeded. Eventually, a militia of noble servitors (dvoriane) and townspeople of the northeast, based in Nizhni Novgorod, expelled the Poles from Moscow, drove back the Swedes and Cossacks, and elected young MICHAEL Romanov as tsar in 1613. The ROMANOV dynasty was to rule Russia until 1917.

An Era of Conflict

▲PRODIGY(R) interactive personal service 06/25/93 11:51 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

RUSSIA, HISTORY OF

Beneath a veneer of traditional forms and static structures profound changes took place in the course of the 17th century, changes that resulted in religious, cultural, political, and socioeconomic disarray. Efforts at reforming the church

structure and at modernizing the ritual along Byzantine and Ukrainian lines, led by NIKON (patriarch from 1652 to 1666), were resisted in the name of earlier spiritualist traditions by large segments of the population (led by monks and parish priests). These OLD BELIEVERS, about 25 percent of the population, were persecuted by the state and virtually split away from official culture and civil society. In suppressing the Old Believers the church lost much of its moral authority and autonomy vis-a-vis the state.

The cultural gap between the elites and the people was deepened by political, social, and economic conflicts: urban strife at times threatened the stability of the regime itself (for example, the salt riots of Moscow, 1648, and revolts in Pskov and Novgorod, 1650). The military servitors' struggle to establish full control (legalized by the Code of 1649) over their peasants led to numerous revolts. In 1670-71 dissatisfied Cossacks, persecuted Old Believers, escaped serfs, and disgruntled urban elements joined forces under Stenka RAZIN in a revolt that swept the entire Volga valley and threatened Moscow itself.

The religious crisis exacerbated the cultural conflict over the extent and character of Westernization. Trade contacts, especially with England and the Dutch, brought foreigners to Russia, and diplomatic exchanges grew more frequent as Russia became involved in European military and diplomatic events. The importation of Western technological innovations for military purposes brought in their wake foreign fashions and cultural goods.

The trend was reinforced following the incorporation of eastern Ukraine (1654). The ecclesiastical academy in Kiev (founded in 1637 by the Ukrainian churchman Peter Mohyla) educated future clergy (and some laymen) according to contemporary European neoscholastic philosophical and juridical curricula; its graduates often continued their studies at central and western European universities. Better trained and more learned than the native Muscovite clerics, the graduates of the Kievan academy were welcomed in Moscow. They were the first to organize regular schools there (for example, the

ACADEMIC AMERICAN ENCYCLOPEDIA

RUSSIA, HISTORY OF

Greco-Latin Slavonic Academy), and they brought Western political and juridical works and belles-lettres to the Kremlin court. The winds of culture and art blowing from the west also helped change Muscovite tastes in architecture, icon painting, church music, and poetry--changes in style that are usually labeled Moscow baroque. These foreign and innovative influences helped smooth the path for the forceful Europeanization that followed under Peter I.

The government, especially under Tsar ALEXIS (r. 1645-76), tried to cope with the difficulties by centralizing the local administrations (prikazy, or departments) under direct supervision of the boyar дума and the tsar, assisted by professional hereditary clerks (diaki). Naturally, the fiscal burden grew in proportion to centralization. To ensure domestic control and to carry on an active foreign policy (for example, the annexation of the Ukraine in 1654 and wars with Poland leading to a "perpetual peace" in 1686), a professional army of streltsy (musketeers) and foreign mercenaries and modernized technology were introduced. Although absolutism was retained intact, factionalism and palace coups became more frequent and made pursuing coherent policies difficult. When Tsar Fyodor III died in 1682 the situation was ripe for the energetic intervention of a genuine leader. After the brief but tumultuous regency of SOPHIA, 1682-89, Fyodor's half brother Peter grasped the opportunity.

The Reforms of Peter the Great

By dint of his driving energy and ruthlessness, PETER I (r. 1682-1725) transformed Russia and brought it into the concert of European nations. A struggle of almost 20 years with CHARLES XII of Sweden (1700-21; see NORTHERN WAR, GREAT) and wars with Ottoman Turkey (1710-11) and Persia (1722-23) radically changed Russia's international position (symbolized by Peter's assumption of the new title of emperor in 1721). By the Treaty of Nystad (1721) with Sweden, Russia acquired the Baltic province of LIVONIA (including Estonia and most of Latvia), giving it a firm foothold on the Baltic Sea and a direct relationship with western Europe. In the south gains were modest, but they marked the beginning of a Russian imperial offensive on the Black and Caspian seas.

These territorial gains, requiring much effort and great expenditures of labor and resources, forced Peter to transform

ACADEMIC AMERICAN ENCYCLOPEDIA

RUSSIA, HISTORY OF

the institutional framework of the state and to attempt a restructuring of society as well. The central administration was streamlined along functional lines: a set of colleges on the European model displaced the prikazy, and a senate of appointed officials replaced the boyar дума; the church was put under direct state administration with the abolition of the patriarchate and the establishment of a Holy Synod (1721) of appointed ecclesiastical members supervised by a lay official. A navy was created, and the army was reorganized along professional Western lines, the peasantry furnishing the recruits and nobility the officers. The local administration, however, remained a weak link in the institutional chain, although it maintained the vast empire in obedience. The peasantry was subjected to compulsory labor (as in the building of the new capital, SAINT PETERSBURG, begun in 1703) and to military service, and every individual adult male peasant was assessed with a head, or poll, tax. By these measures the state severed the last legal ties of the peasants to the land and transformed them into personal serfs, virtually chattel, who could be moved and sold at will.

Other classes of society were not immune from state service either. Compulsory, lifelong service was imposed on the nobility, and their status was made dependent on ranks earned in military or administrative office (the Table of Ranks of 1722 also provided for automatic ennoblement of commoners through service). State service required education, and Peter introduced compulsory secular, Westernized schooling for the Russian nobleman. While resistance to compulsory service gradually forced its relaxation, education became an internalized value for most nobles who were culturally Westernized by the mid-18th century.

Peter failed to reshape the merchants into a Western bourgeoisie, however, and his efforts at modernizing the economy had mixed results. The clergy turned into a closed castelike estate, losing its spiritual and cultural influence. The limitations of Peter's reforming drive were due to the inherent paradox of his policy and approach: he aimed at liberating the creative forces of Russian society, but he expected to accomplish this liberation only at his command and through compulsion, at a pace that precluded an adaptation of traditional patterns and values. He succeeded in transforming the upper class but failed to change the common people; the deep cultural gulf in the long run undermined the regime.

ACADEMIC AMERICAN ENCYCLOPEDIA

RUSSIA, HISTORY OF

The Imperial Succession

Peter's impetuousness did not allow the new structure and patterns to congeal, and after his death (1725) instability plagued the new institutional setup. Having had his son, Alexis, tortured to death for alleged treason, Peter abolished the traditional practice of succession, declaring (1722) that the emperor could choose his successor. For the next half-century the throne was exposed to a series of palace coups instigated by cliques of favorites and dignitaries with the support of the Guards regiments. After the reign (1725-27) of Peter's widow, CATHERINE I, Peter II (r. 1727-30), ANNA (r. 1730-40), Ivan VI (r. 1740-41), ELIZABETH (r. 1741-62), and CATHERINE II (r. 1762-96), who supplanted her husband, PETER III, all came to the throne in this manner. The only serious attempt at limiting the power of the throne (1730), however, failed because of divisions among the nobility and their continued dependence on state service. The autocracy managed to keep the nobility in subordination by promoting the economic status of that class through salaries, gifts, and the extension of its legal rights over the serfs, particularly following the traumatic experience of the great peasant uprising (1773-75) under Yemelian PUGACHEV.

The government proved unable to regularize its structure and practices through a code of laws because it was feared that such a code would delegate power to impersonal institutions. Personalized authority was favored by most subjects, however, as a protection against abuses of officials and as a source of rewards.

The tension between a rational and automatic rule of law and a personalized authority was never resolved in imperial Russia.

Expansion and Westernization

Two important processes dominated the 18th century. The first was imperial expansion southward and westward. The southern steppe lands were gradually settled by Russians, and the autonomous local social groupings--especially the Cossacks (whose hetmanate in the Ukraine was abolished in 1764)--lost

their status and were assimilated into Russian serf society. The process was formally completed by the Treaty of Kucuk Kainarji (1774), ending the first major RUSSO-TURKISH WAR, by

ACADEMIC AMERICAN ENCYCLOPEDIA

RUSSIA, HISTORY OF

which Russia secured the northern shore of the Black Sea, and by the annexation (1783) of the Crimea, which put an end to the nomadic threats from the southeast. By extending (1783) serfdom to the Ukraine the economic integration of that area with Russia was achieved, and its large, prosperous estates were soon able to feed a growing urban population and to export grain abroad.

The empire's expansion westward was the result of the Partitions of Poland (1772, 1792, 1795; see POLAND, PARTITIONS OF), which awarded Russia most of the eastern and central regions of the Polish-Lithuanian Commonwealth. This expansion enhanced Russia's economic potential and brought it closer to western Europe, but it also burdened the empire with unsolvable national and religious problems and saddled it with onerous diplomatic, military, and police tasks.

In the past, apart from the incorporation of small Finnish and Siberian tribes, Muscovy had known only one major territorial conquest involving non-Russian and non-Christian peoples--that of the Tatars of the Volga in the 16th century. Their elites were quite successfully incorporated into the tsar's service nobility (most eventually became Christians); as for the common folk, they were subject to a special tribute (iassak), but their internal tribal affairs were left to the care of traditional elders and chieftains. The imperial acquisitions of the 18th century, however, brought a number of new nationalities under Russian rule: Ukrainians, Poles, Crimean Tatars, Jews, Estonians, Latvians, Lithuanians, and Baltic Germans. Wherever workable, these nationalities' elites were recruited into the military and civil establishments. The common people continued to be allowed their own traditional institutions, provided they paid their taxes. The Russian church was discouraged from proselytizing. Legal disputes were resolved according to native customary law if no Russians were involved; otherwise Russian law took precedence. Before the birth of modern nationalism in the 19th century this approach worked well enough so that the imperial administration and the

Russian elites were able to ignore the multiethnic character of the empire.

The second process shaping 18th-century Russia is best characterized as the cultural Westernization of the Russian elites. It was furthered by the establishment of new educational institutions (the Academy of Sciences, 1725; the

RUSSIA, HISTORY OF

University of Moscow, 1755; and military and private schools), the creation of a modern national literature along Western lines (exemplified in the work of Mikhail LOMONOSOV and Aleksandr SUMAROKOV), and the beginnings of scientific research and discoveries (Lomonosov). Increased sophistication heightened yearnings for free expression and implementation of enlightened Western moral and social values. It led to a conflict between state control and educated society's demand for creative freedom and to the emergence of an oppositionist intelligentsia. In 1790, for example, Aleksandr RADISHCHEV denounced the moral evils of serfdom in *A Journey from Saint Petersburg to Moscow*.

Imperial expansion and cultural Westernization were accompanied by economic modernization. Russia became a notable producer of iron, lumber, and naval stores (pine products) and witnessed the expansion of urbanization and social amenities. Catherine II intensified these developments and reaped their benefits. In February 1762 the nobles had been freed from compulsory state service by Peter III and had been given the right to travel abroad. But their corporate status, security of person and property, and local administrative function had not been clarified. This was even truer of the other free classes. In order to obtain reliable and comprehensive information on conditions in the empire (and to bolster her own legitimacy) Catherine convoked (1767) an assembly of elected delegates from the free estates of the realm. The deputies were expected to draft and bring to the assembly "instructions" (nakazy) listing the conditions and needs of their electors. This "Legislative Commission" was soon disbanded, but the instructions and debates gave Catherine ample material for a picture of what the various free classes of the population expected from her. In response she decided that Russian society should contribute more directly to economic activity.

To this end she fostered security of property and person, at least for members of the upper classes. In implementing this goal she followed two paths. First, by the Statute on the Provinces (1775) she concentrated the administration of the empire by breaking up its territory into manageable units (guberniia) under appointed governors responsible to the sovereign and accountable to the senate. Governors were to be assisted by boards of officials organized according to function and, on the district level, by police officers elected by, and from among, the local nobility or wealthy urban population.

ACADEMIC AMERICAN ENCYCLOPEDIA

RUSSIA, HISTORY OF

Second, the empress planned to promote the formation of a civil society by granting the three principal estates of the realm the right to form corporations. These would serve to register their members, and to protect group interests, as well as each individual member's person and property. The Charter to the Nobility (1785) put local resident nobles in charge of district police, some judicial matters, and the protection and supervision of orphans, widows, and incapacitated persons. The Charter to the Towns (1785) similarly gave an active administrative role to urban elites, while reserving paramount authority to governors and appointed officials. A third charter giving state peasants a degree of self-government on the village level was drafted but never implemented.

Though the practice fell far short of the intention, Catherine II did lay the foundations for the emergence of a provincial civic and cultural life--a prerequisite for the modernization of Russia in the 19th century.

THE 19TH CENTURY

Alexander I

Catherine's grandson ALEXANDER I, who succeeded to the throne after the brief reign (1796-1801) of his unbalanced father, PAUL I, intended to give regular institutional form to the results of the social and cultural evolution of the 18th century. The first years of Alexander's reign were marked by intensive efforts at reforming the administration and at expanding the educational facilities. Although the reforms did

not bring about constitutionalism or limit the autocracy, they did inaugurate rapid bureaucratization with better trained officials.

Russia's involvement in the NAPOLEONIC WARS proved in some ways an impediment to the normal evolution of the country. NAPOLEON I's invasion of Russia in 1812, although ending in his own defeat, was hardly a victory for Russia. The wars proved costly, and the ultimate political gains (Finland, penetration into the Caucasus) were rather slim despite Alexander's diplomatic role after 1815 (notably in the HOLY ALLIANCE). On the other hand, the reconstruction of devastated territories along the route of the French invasion and of Moscow (largely destroyed by fire during the French occupation) gave great impetus to an economic takeoff and involved entrepreneurial initiatives by peasants and urban commoners. It resulted in a

RUSSIA, HISTORY OF

rapid expansion of textile manufactures and the building trades, which generated capital and resources for later Russian industrialization.

During the wars the younger generation of educated society had acquired self-confidence and a desire to be of use to their country and people; upon the return of peace they tried to put their ideals into practice. Unavoidably, this led to a clash with a government that was loath to give society genuine freedom and that, after 1815, became more restrictive and obscurantist. Secret societies were organized under the leadership of progressive officers, and, on the sudden death of Alexander I in December 1825, they tried to take over the government. This abortive insurrection of the DECEMBRISTS traumatized Alexander's successor, his brother NICHOLAS I, into a policy of reaction and repression.
Nicholas I

Nicholas I's reign, however, was by no means static, and it proved seminal in many respects. In spite of strict censorship, the golden age of Russian literature occurred with the work of Aleksandr PUSHKIN, Nikolai GOGOL, the young Fyodor DOSTOYEVSKY, Leo TOLSTOI, and Ivan TURGENEV. Accompanying this literary flowering, discussion circles sprang up in Moscow and Saint Petersburg in which the intelligentsia debated Russia's identity, its historical path and role, and its relationship to

western Europe (the SLAVOPHILES AND WESTERNIZERS represented the two main lines of interpretation that emerged).

Nicholas was unfavorably disposed to the humanities and limited admissions to the universities, but he promoted technical and professional training. During his reign a number of technical institutions of higher learning were founded, and state support for needy students in professional schools was expanded. By the end of the reign a cadre of well-trained professionals and officials had been prepared to carry out reforms. Nicholas's government also brought to a successful conclusion the codification of laws (1833; the achievement of Mikhail SPERANSKY), which enabled an orderly and systematic economic development of the country. The building of railroads was initiated, the currency was stabilized, and protective tariffs were introduced. As a result private enterprise was activated, especially in consumer goods (textiles), in which even peasant capital and skill participated. These developments only served to underscore the backward nature of an agrarian economy based

RUSSIA, HISTORY OF

on serf labor. Nicholas was well aware of this, but, fearing political and social disturbances, he did not go beyond discussions in secret committees and the improvement of the administration of state peasants.

All the while, however, his government encouraged middle-rank officials to collect accurate and comprehensive data on Russia's economic and social condition. The Imperial Geographic society sponsored expeditions and statistical surveys that eventually provided the government with information needed to undertake reforms.

The government's timidity was conditioned not only by fear of a peasant uprising and a distrust of the nobility but also by its international policies. Nicholas's reign was for the most part peaceful, although Russia did participate in securing Greek independence (1828-29) and in curtailing Turkish power in the Black Sea. Nicholas also acted as the "gendarme of Europe" when he crushed the Polish insurrection of 1831-33 and helped Austria subdue the Hungarians in 1849. The empire further expanded in the Far East (in the Amur River valley). At the end of his reign Nicholas embroiled Russia in the CRIMEAN WAR

(1853-56). Although the immediate cause of the war was a dispute over the guardianship of the Holy Places in Palestine, underlying the conflict was the EASTERN QUESTION, the prolonged dispute over the disposition of the territories of the fast-declining Ottoman Empire. The Russians fought on home ground against British and French troops assisted by Sardinian and Austrian forces. The course of the war revealed the regime's weaknesses, and the death (1855) of Nicholas allowed his son, ALEXANDER II, to conclude a peace (the Treaty of Paris, 1856) that debarred Russian warships from the Black Sea and Straits.

Alexander II and Emancipation of the Serfs

Russian society now expected and demanded far-reaching reforms, and Alexander acted accordingly. The crucial reform was the abolition of serfdom on Mar. 3 (N.S.), 1861. In spite of many shortcomings it was a great accomplishment that set Russia on the way to becoming a full-fledged modern society. The main defects of the emancipation settlement were that cancellation of labor obligations took place gradually, the peasants were charged for the land they received in allotment (through a redemption tax), and the allotments proved inadequate in the

Alexander II and Emancipation of the Serfs

Russian society now expected and demanded far-reaching reforms, and Alexander acted accordingly. The crucial reform was the abolition of serfdom on Mar. 3 (N.S.), 1861. In spite of many shortcomings it was a great accomplishment that set Russia on the way to becoming a full-fledged modern society. The main defects of the emancipation settlement were that cancellation of labor obligations took place gradually, the peasants were charged for the land they received in allotment (through a redemption tax), and the allotments proved inadequate in the long run. The last was a consequence of demographic pressures due to the administrative provisions of the act that restricted the mobility of the peasants and tied them to their village

commune, which was held responsible for the payment of taxes; the former serfs remained second-class citizens and were denied full access to regular courts. Nevertheless, 20 million peasants became their own masters, they received land allotments that preserved them from immediate proletarianization, and the emancipation process was accomplished peacefully.

Three other major reforms followed emancipation. The first was the introduction (1864) of elected institutions of local government, zemstvos, which were responsible for matters of education, health, and welfare; however, the zemstvos had limited powers of taxation, and they were subjected to close bureaucratic controls. Secondly, reform of the judiciary introduced jury trials, independent judges, and a professional class of lawyers. The courts, however, had no jurisdiction over "political" cases, and the emperor remained judge of the last resort. Finally, in 1874, the old-fashioned military recruiting system gave way to universal, compulsory 6-year military service.

Taken together, the reforms marked the end of the traditional socioeconomic system based on serfdom, and set Russia fully on the path to an industrial and capitalist revolution that brought problems of urbanization, proletarianization, and agrarian crisis in its wake. In part the difficulties resulted from unpreparedness and reluctance on the part of landowners (and many among the intellectual elites) to make necessary adjustments in their economic practices and social attitudes; but they were also caused by government policies that hindered the emergence of a genuine capitalist bourgeoisie and industrial labor force.

ACADEMIC AMERICAN ENCYCLOPEDIA

RUSSIA, HISTORY OF

The impetus for reform was thwarted and arrested by external and domestic events. Externally, the Polish rebellion of 1863-64 gave pause to the government and, by exacerbating nationalistic feelings, strengthened the conservative opposition to further reforms. The Russo-Turkish War of 1877-78 undermined the financial equilibrium, and chauvinistic passions were aroused when the Treaty of San Stefano, which greatly increased Russian influence in the Balkans, was substantially revised by the Congress of Berlin (see BERLIN,

CONGRESS OF). At home in the 1860s radical university students and nihilist (see NIHILISM) critics such as Nikolai CHERNYSHEVSKY voiced dissatisfaction with the pace and direction of the reforms. Radical associations were formed to propagandize socialist ideas, and student youth "went to the people" in 1874-76 to enlighten and revolutionize the peasantry. Repressed by the government, the young radicals turned to terrorism. Eventually a group of NARODNIKI (populists) called the People's Will condemned the emperor to death, and after several dramatic but unsuccessful attempts they killed him on Mar. 13 (N.S.), 1881.

Alexander III

Alexander II's violent death inaugurated the conservative and restrictive reign of his son ALEXANDER III. Nonetheless, the process of social and economic change released by the reforms could not be arrested. Now society proved more dynamic and took the lead in the drive for modernization and liberalization; the government, on the other hand, incapable of giving up its autocratic traditions, acted as a barrier. The deepening agrarian crisis--dramatized by the famine of 1891--turned the active elements from criticism to overt opposition. At the same time, industrialization energetically pushed by Sergei WITTE, minister of finance (1892-1903), brought in its wake labor conflict, urban poverty, and business cycles.

Expansion and Russian Nationalism

The acquisition of CAUCASIA, under Nicholas I, had required lengthy and difficult campaigns against mountain populations using guerrilla tactics to defend themselves. During the reign of Alexander II, largely on local military initiative, the independent or autonomous Muslim principalities of CENTRAL ASIA

ACADEMIC AMERICAN ENCYCLOPEDIA

RUSSIA, HISTORY OF

were brought under Russian control and turned into virtual colonies for economic exploitation and peasant settlement.

Paralleling the south and southeastward expansions of the empire, the governor-general of Siberia, Nikolai N. Muraviev, forced China to relinquish control over the lower course of the

Amur River (Treaty of Aigun, 1858), opening up the Pacific shore to Russian penetration and settlement. The Russian Empire thus increased its territory and developed a genuinely colonial approach to the newly incorporated lands and peoples. With the possible exception of Georgia (incorporated early in the 19th century), native leadership was not absorbed into the Russian nobility or cultural elite, as had been the case in earlier conquests. New administrative practices developed in these territories with the help and participation of the military resulted in the imposition of oppressive rule and socio-economic discrimination against the native populations.

The Slavophile-Westernizer debates over the nature of Russian national identity in the 1830s undoubtedly contributed to a more aggressive and self-centered sense of Russian nationalism, which received strident expression during the Polish revolt of 1863 and the Russo-Turkish War of 1877-78. It prompted the government to embark on a consistent policy of Russification and harsh repression of nationalist movements among the non-Russian peoples of the empire. Imperial decrees restricted the use of the Ukrainian language and the privileged status of the Germans in the Baltic provinces. Paradoxically, the actions against the Baltic Germans encouraged the growth of nationalist feeling among the Latvians and Estonians, whom the Germans had dominated. The suppression of the Polish uprising of 1863 was followed by energetic Russification measures aimed at eliminating the Polish language and Polish culture from public life.

Under Alexander III, discriminatory laws against Jews, involving residential restrictions and limited access to secondary and higher education, were reinforced and harshly applied. At the same time, the government did little to control pogroms or anti-Jewish riots (see POGROM). Hundreds of thousands of Jews emigrated to Western Europe and the United States, and many who aspired to professional education and cultural assimilation were driven into the arms of radical political parties.

ACADEMIC AMERICAN ENCYCLOPEDIA

RUSSIA, HISTORY OF

These policies continued unabated under Alexander's son Nicholas II, whose government also curtailed Finland's

traditional autonomy.

Nicholas II

Nicholas succeeded his father in 1894. The new emperor soon dashed society's hopes for political and social reform. To deflect attention from the worsening social situation and to neutralize the revitalized revolutionary movement, especially among the workers, the government embarked on imperialist adventures in the Far East, provoking a war with Japan (1904-05; see RUSSO-JAPANESE WAR). Russia suffered a humiliating defeat, although the peace terms (Treaty of Portsmouth, 1905) were less onerous thanks to the mediation of U.S. president Theodore ROOSEVELT and Japan's exhaustion.

The war triggered widespread disturbances within Russia, including rural violence, labor unrest (in Saint Petersburg troops fired on a large crowd of demonstrating workers; Bloody Sunday, Jan. 22, 1905), and naval mutinies (most notably, that led by sailors of the battleship Potemkin in Odessa, June 1905). The turmoil of the RUSSIAN REVOLUTION OF 1905 culminated in the general strike of October, which forced Nicholas II to grant a constitution. Russia received a representative legislative assembly, the DUMA, elected by indirect suffrage. The executive, however, remained accountable only to the emperor. Limited as its powers were (the suffrage was further restricted in 1907), the Duma made the government more responsive to public opinion. From 1906 to 1911 the government was directed by Pyotr STOLYPIN, who combined repressive action with land reforms to improve the position of the peasants.

The new political activity contributed to the remarkable upsurge of Russia's artistic and intellectual creativity (called the Silver Age) that lasted until the outbreak of World War I in 1914. The Silver Age marked Russia's coming of age as a contributing participant in Western culture. This happened, first of all, because of the high level of professionalization attained by Russian scholars, scientists, and artists. The process had been initiated in the field of humanities under Alexander I and was confined at first to the nobility. The reign of Nicholas I marked Russia's take-off in science and scholarship within the framework of the universities and the

RUSSIA, HISTORY OF

Academy of Sciences. In the 1860s prominent Russian scientists such as N. I. LOBACHEVSKY and D. I. MENDELEYEV received full recognition in the West.

After the reforms of Alexander II, the needs of the zemstvos, the new judicial system, and of the rapidly developing industrial system produced an exponential increase in the number of technicians and professionals in such areas as law, medicine, engineering, agronomy, and statistics. Professional associations aimed at playing an active role in shaping government and public policies in their fields for the benefit of society.

By the first decade of the 20th century Russia had moved to the forefront of scholarly and scientific progress; the contributions of Russian scientists in such areas as chemistry, aeronautics, linguistics, history, archaeology, and statistics were universally recognized.

Equally significant was the renaissance of religious life, and growing interest in the question of church involvement in social problems. Reformist laymen and clergy demanded greater independence for the church, calling for a national church council to address the needs and define the character of Russia's ecclesiastical institutions. Closely allied to the religious renaissance was the development of the personalist-existentialist school of Russian philosophy by N. A. BERDYAYEV, N. O. Lossky (1870-1965), L. Shestov (1866-1938), and others.

Last, but not least, the Silver Age witnessed an extraordinarily creative outburst in the arts. The composer Igor STRAVINSKY, ballet impresario Sergei DIAGHILEV, and the painter Wassily KANDINSKY each had a strong influence on the emergence of avant-garde modernism before and after World War I. In the same period, CONSTRUCTIVISM and SUPREMATISM were original Russian contributions to abstract art (see RUSSIAN ART AND ARCHITECTURE; RUSSIAN MUSIC).

Thus the years 1905-14 were a period of great complexity and ferment. To many this feverish intellectual creativity, which had its social and political counterpart in rural unrest, industrial discontent, revolutionary agitation, and nationalist excesses (for example, the pogroms against the Jews), proved that the imperial regime was nearing its inevitable end, which the outbreak of war only served to delay. On the other side,

ACADEMIC AMERICAN ENCYCLOPEDIA

RUSSIA, HISTORY OF

liberals and moderate progressives saw in these phenomena harbingers of Russia's decisive turn to political democracy and social and economic progress, which was abruptly stopped in 1914.

In any event Russia went to war in August 1914. Determined to prevent further Austro-Hungarian encroachment in the Balkans, the Russian government rallied to the support of Serbia when Austria-Hungary declared war on that Balkan nation. Russia's alliance with France and Britain (see TRIPLE ENTENTE) and Austria-Hungary's with Germany helped transform the local Balkan conflict into WORLD WAR I. The strains of that bloody and disastrous conflict produced a breakdown of both the political system and the social fabric in Russia. Food riots in Petrograd (formerly Saint Petersburg) and other cities toppled the monarchy in March (N.S.; February, O.S.) 1917.

The Russian Revolutions of 1917

Following the abdication of the emperor the Duma established a provisional government, headed first by Prince Georgy Lvov (1861-1925) and later by Aleksandr KERENSKY. The government's authority was challenged, however, by an increasingly radical Soviet (council) of Soldiers' and Workers' Deputies, and it could not stem the tide of disintegration. Eventually agrarian unrest, mass desertions at the front, turmoil in the cities, and disaffection of the non-Russian nationalities gave the Bolsheviks (see BOLSHEVIKS AND MENSHEVIKS) under Vladimir Ilich LENIN an opening to seize power in November (N.S.; October, O.S.) 1917. Thus the second of the two RUSSIAN REVOLUTIONS OF 1917 occurred, leading to the establishment of the UNION OF SOVIET SOCIALIST REPUBLICS.

ACADEMIC AMERICAN ENCYCLOPEDIA

UKRAINE

{yoo-krayn'}

Ukraine was formerly one of the republics of the USSR. Along with the other Soviet republics, it became independent in 1991. Ukraine is bordered on the north by Belarus, on the north and east by Russia, on the south by the Sea of Azov and the Black Sea, on the southwest by Romania and Moldova, and on the west by Hungary, Slovakia, and Poland. One of the largest European countries, it ranks second in area (after Russia), and sixth in population. The capital of Ukraine is KIEV. For much of its history, the country has been subject to Russian and Polish influence.

LAND AND RESOURCES

Ukraine is mostly flat plains or gently rolling hills. Elevation generally rises from the southern Black Sea region northward, although the northernmost region of Polesie is a vast marshy lowland. The only mountain ranges are the CARPATHIANS in the extreme west and the Yayla Range in the southern CRIMEA. The major river, fed by numerous tributaries, is the DNEPR (Dnpr), which bisects the country in a broad arc before emptying into the Black Sea. Other important waterways include, in the west, the DNESTR (Dnistr) and the Southern Bug (Boh) rivers, which also drain into the Black Sea, and, in the east, the DONETS, which flows into the Sea of Azov.

Vegetation and Soil

Vegetation is divided among three zones from north to south: the forest (coniferous and deciduous) zone, the mixed forest-steppe zone, and the STEPPE. Forests cover less than

15% of the land. Almost half of Ukraine--the steppe and most of the forest-steppe zone--is covered with some of the world's most fertile chernozem soil, the basis for the country's rich agriculture. Human settlement has destroyed much of Ukraine's natural flora and fauna.

Climate

Most of Ukraine has a moderately continental climate, though it is alpine in the Carpathians and subtropical in parts of the Crimea. Average temperatures vary from -8 deg C (18 deg F) in the north and 4 deg C (39 deg F) in the south in January, to 18 deg C (64 deg F) in the north and 24 deg C (75 deg F) in the

Copyright (c) 1993 Grolier Electronic Publishing, Inc. All rights reserved.
▲PRODIGY(R) interactive personal service 06/25/93 11:55 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

UKRAINE

south in July. Annual precipitation also varies, from an average of 1500 mm (59 in) in the Carpathians to 300 mm (12 in) on the Black and Azov sea coasts; the south often suffers from drought.

Resources

Ukraine has large reserves of peat, natural gas, and coal but insufficient oil reserves to meet its energy needs. Iron ore and other mineral resources are most abundant in the DONETS BASIN (Donbas) and the Dnepr Basin, which are the nation's industrial heartlands.

PEOPLE

The two principal ethnic groups in Ukraine are Ukrainians and Russians. In 1989 ethnic Ukrainians formed 73% of the population, and ethnic Russians 22%. In the more rural western and central regions Ukrainians make up 90% or more; their percentage is substantially lower in the industrialized east and south (in the Donbas it is just over 50%), where a correspondingly higher proportion of Russians exist. Only since the 1970s have a majority of Ukrainians been city dwellers, whereas the Russians are 90% urban; many large cities are predominantly Russian-speaking. Use of the Ukrainian language, a East Slavic language closely related to Russian, is now being promoted in all spheres of life. In the Crimea, from which the native TATAR were deported in

1944, the population is two-thirds Russian and one-third Ukrainian. Since the late 1980s the Tatars have been returning in large numbers and pressing their demands for the reconstitution of a Crimean Tatar homeland.

Religion

Ukrainians have traditionally been Eastern Christians, divided since 1596 into an Orthodox majority and a minority of EASTERN RITE (Uniate) Catholics, who predominate in the west. Both the Ukrainian Autocephalous Orthodox church and the Ukrainian Catholic (Easter Rite) church were banned under Stalin, but have reemerged and grown in strength since 1989. Separate from these is the Ukrainian Orthodox church, which is subject to the Moscow patriarchate. Most Russian believers are Orthodox. Latin Rite Catholicism is limited to ethnic Poles and Hungarians. Protestant, Jews, and Muslim (mostly Crimean

UKRAINE

Tatar) communities also exist.

Culture

Ukrainian folk art and music are internationally famous. Centuries of foreign rule inhibited the development of a vernacular Ukrainian literature. Despite tsarist Russification policies, however, such a literature did begin to flourish in the 19th century, exemplified in the works of Taras SHEVCHENKO and others. Party controls and official Russification were also hindrances in the Soviet period, but the 1920s and 1960s were times of considerable cultural creativity. Since the late 1980s there has been a cultural revival, especially through the medium of the Ukrainian language.

Education and Health Care

Literacy has been nearly universal since the mid-20th century. All education through the university level is free and compulsory through the eighth grade. Medical care is free of charge, but medical services have deteriorated since the 1970s.
ECONOMIC ACTIVITY

Ukraine's common designation as the "breadbasket of Europe"

reflects the traditional importance of agriculture in the country's economy. Industrialization began in the late 19th century and continued under Soviet rule, mostly in the Donbas and the central Dnepr region. Central planning, directed by Moscow, led to sectional imbalances and reliance on supplies from other Soviet republics, which resulted in serious economic difficulties when independence came. The transition to a market economy, the declared goal of Ukraine's government, has been slow. Legislation on privatization was enacted in 1992; some progress toward that end was made in the service sector, but agriculture remained almost totally collectivized and factories continued to be run by state-appointed managers.

Over 40% of the labor force is employed in industry. Despite some progress in regional equalization, the east remains the most industrialized area, followed by the south; the western, and especially the central regions still lag in industrial development. Extractive industries (the mining of coal, iron ore, and other minerals) have long been important. Soviet economic policies in Ukraine favored heavy machine industry to the detriment of light industry and consumer goods. Much of

ACADEMIC AMERICAN ENCYCLOPEDIA

UKRAINE

Ukraine's pre-independence industry was devoted to the production of military equipment, and the retooling of plants for civilian production is a high priority in the present economy.

Ukraine's leading industrial centers include Kiev, KHARKOV (Kharkiv), and DONETSK (Donets) in the east; DNEPROPETROVSK (Dnipropetrovsk), ZAPOROZHYE (Zaporizhzhia), and KRIVOI ROG (Kryvyi Rih) in the central Dnepr basin; and the Black Sea ports of ODESSA, Kherson, and Nikolayev (Mykolaiv), which are important for the shipbuilding industry.

GOVERNMENT

Until 1990 political power was the monopoly of the Communist party, whose Ukrainian branch was strictly subordinated to the central party organs in Moscow. All institutions of government, in Kiev and on the local level, were controlled by the party and led by party officials.

In emulation of the Soviet Communist party and its leader

Mikhail GORBACHEV, the Ukrainian party surrendered its monopoly of power early in 1990. The first and partially contested elections in Ukraine were held in March of that year. In the newly elected 450-member Supreme Council (parliament), orthodox Communists held a slim but controlling majority of 53%; the Democratic Bloc (an alliance of opposition groups) accounted for 30%, and reform Communists for the remainder. Weakening Soviet central power permitted Ukraine to adopt a declaration of sovereignty in July 1990; independence was proclaimed, and the Communist party was banned in August 1991. Well over a dozen new political parties have emerged, including the Socialist party (with a membership consisting largely of former Communists), the liberal-democratic Ukrainian Republican party, the moderate new Ukraine party, and the environmentalist Green World party.

In the summer of 1991 parliament voted to create the post of president, and the first presidential election was held in December. Executive power is exercised by a council (cabinet) of ministers headed by the premier, who is appointed by the president subject to parliamentary approval. In 1993 the president was Leonid M. Kravchuk. Legislation in the spring of 1992 allowed the appointment of presidential representatives in the administrative regions (oblasts) to oversee the implementation of national legislation and executive orders.

ACADEMIC AMERICAN ENCYCLOPEDIA

UKRAINE

The first draft of a new constitution was released for national discussion in mid-1992.

The Crimea was recognized as an autonomous republic within Ukraine in 1991.

HISTORY

In the 1st millennium BC, Ukraine's Black Sea coast and the Crimean Peninsula became an outpost of Greek, and later Roman and Byzantine, civilization. The steppe hinterland, by contrast, was for centuries the domain of nomadic tribes arriving in succession from Central Asia. Beginning in the 6th century AD, East Slavic tribes settled the interior.

In the 9th century the first historic state on Ukrainian

territory rose around the city of Kiev. From its core in Ukraine, the Kievan state expanded rapidly toward the northwest into modern Belarus, and northeast into what is now Russia (see RUSSIA, HISTORY OF). The name Rus', by which the Kievan state came to be known, was at first applied to the environs of Kiev and later to the entire territory ruled by members of the Kievan dynasty. In 988, VLADIMIR I introduced Byzantine (Orthodox) Christianity as the official religion of the realm, and under his successors a new Christian culture developed.

In the 12th and 13th centuries Kievan Rus' was in decline as a result of shifting trade routes, nomadic incursions from the steppe, and separatist tendencies among its various principalities. The final blow to Kiev was the Mongol invasion of the mid-13th century. But already the focus of power had shifted to the Galician-Volhynian principality (in present western Ukraine), which became the main heir to the Kievan legacy.

In the 14th century GALICIA fell under the rule of Poland, and most of the rest of Ukraine came under the Grand Duchy of Lithuania. In 1569, when Lithuania formed a political union with Poland, virtually all Ukrainian lands were transferred to the direct jurisdiction of the Polish crown. The expansion of Polish magnate landownership, the Polonization of the local nobility, and the inroads of Roman Catholicism at the expense of Orthodoxy engendered social, religious, and national tensions in Ukraine. Religious strife increased when a majority of the Orthodox bishops in the Polish-Lithuanian Commonwealth accepted union with Rome in 1596. The strongest

ACADEMIC AMERICAN ENCYCLOPEDIA

UKRAINE

opponents of the new Uniate church were the COSSACKS, who had developed into a powerful military force on Ukraine's steppe frontier and staunchly resisted Polish attempts to bring them under control.

The rising tensions exploded in a vast Cossack insurrection under the leadership of Bohdan CHMIELNICKI (Khmelnytsky) in 1648, which was joined by the peasantry in revolt against serfdom. Rebel activity was directed not only against the Poles but also the Jews, whom the peasants identified with the Polish regime. Initial success encouraged Chmielnicki to begin the formation of a Ukrainian Cossack state independent of

Poland. However, an agreement with Moscow in 1654 made him a vassal of the Russian tsar, and in 1667, Ukraine was partitioned between Muscovy and Poland. For a time Russian Ukraine enjoyed self-rule under its hetman (prince). After Hetman Ivan MAZEPA made a bid (1708-09) for independence in alliance with Sweden, however, Ukrainian autonomy was severely curtailed; it was finally abolished by Catherine II in the 1760s. In the late 18th century the Russian Empire absorbed the remainder of Ukraine in the partitions of Poland, except for Galicia, which was annexed by Austria. At the same time, Russia's conquest of the Crimea opened up the southern steppes and the Black sea coast to Ukrainian settlement.

In the 19th century a modern national movement developed in Ukraine. Russia's response was repression, denial of Ukrainian nationality, and a ban on the Ukrainian language (1863 and 1876). A freer atmosphere for Ukrainian self-expression existed in Austrian Galicia.

After the collapse of both the Russian Empire and Austria-Hungary at the end of World War I, the two Ukrainian regions were briefly reunited in an independent state. In 1921, however, Galicia and Volhynia were occupied by Poland, while smaller areas in the west (northern BUCOVINA and RUTHENIA) were annexed by Romania and Czechoslovakia, respectively. Eastern Ukraine, conquered by the Soviets, became the Ukrainian SSR. In the east Stalin's forced collectivization and an artificially induced famine in 1932-33 led to the loss of several million lives. World War II brought massive destruction and further loss of life as Ukraine became the main battlefield between the USSR and Nazi Germany. Postwar Soviet annexation of western Ukraine was resisted by guerilla forces until the early 1950s. The transfer of the

Crimea from Russia to Ukraine in 1954 completed the present configuration of the country.

Under the Ukrainian Communist party leader Petro Shelest (1963-72) a modest national revival occurred but was cut short by Shelest's removal. Arrests of dissenters and cultural leaders followed. The long tenure of Volodymyr Shcherbytsky as party chief was marked by Russification, cultural sterility,

political stagnation, and the disaster of the CHERNOBYL nuclear plant accident in 1986.

Political changes proceeded rapidly after 1989, the year that saw the rise of mass organizations, most notably the Rukh (People's Movement of Ukraine), which pushed for greater autonomy in the last years of Soviet rule. Following the failure of the Moscow coup, independence was proclaimed on Aug. 14, 1991. This was confirmed by 90% of the voters in referendum held on Dec. 1, 1991. On the same day former Communist Leonid Kravchuk was elected to the presidency, defeating the Rukh candidate, V. M. Chornovil, with 62% of the vote to Chornovil's 23%.

After the demise of the USSR, Ukraine joined the other former Soviet republics in forming the COMMONWEALTH OF INDEPENDENT STATES. Disputes with Russia over possession of the Crimea and control of the former Soviet Black Sea fleet subsided after agreements between Kravchuk and Russian president Boris Yeltsin in June and August 1992.

ACADEMIC AMERICAN ENCYCLOPEDIA

BELARUS

{byel-ah-roos'}

Belarus (Byelarus, Belorussia, White Russia) is a landlocked country in Eastern Europe, bordered in the north and east by Russia, in the south by Ukraine, in the west by Poland, and in the northwest by Lithuania and Latvia. MENSK (Minsk) is the capital. Until it achieved independence in 1991, Belarus was the Belorussian Soviet Socialist Republic, one of the republics of the USSR.

In medieval times the territories of modern Belarus successively formed part of the Kievan Rus' state and, from the late 13th century, the Grand Duchy of Lithuania. After the union of Lithuania and Poland in 1569, Polish political and cultural influences became dominant in the area. With the partitions of Poland-Lithuania in the late 18th century Belarus became part of the Russian Empire. An attempt to establish independent statehood after the Russian Revolutions of 1917 proved unsuccessful, and in 1919 Belarus became a Soviet republic under Communist party rule.

LAND AND RESOURCES

Most of Belarus is a flat plain, with little variation in relief. The elevation is generally higher in the north, and a chain of hills runs through the central portion of the country. Marshy lowlands cover the southern region of Polesye (PRIPET MARSHES) in the basin of the Pripyat River. The major rivers drain either westward into the Baltic Sea (the Western DVINA and NEMAN) or southward into the Black Sea (the DNEPR, with its main tributaries, the Berezina and the Pripyat). Numerous streams and lakes are a prominent feature of the landscape, and a network of canals links the navigable waterways. About one-third of the country is covered with forests, mostly coniferous and birch. There is a rich variety of wildlife, including such rare animals as the European bison in the primal forest reserve of Belaya Vezha (Bialowieza) that straddles the Belorussian-Polish border.

Belarus was long thought to be poor in minerals, its natural resources limited to peat, gravel, sands, and clays. Recent surveys, however, have uncovered major deposits of coal, shale, oil, and potassium salts. Limestone, dolomite, and other building materials are also present. The soils are generally poor, and much of the land has been contaminated by

ACADEMIC AMERICAN ENCYCLOPEDIA

BELARUS

radioactivity from the CHERNOBYL nuclear power plant accident of 1986.

The climate is moderately continental. The temperature averages 21 deg F (-6 deg C) in January and 64 deg F (18 deg C) in July. Average annual precipitation is 550-700 mm (22-28 in).

PEOPLE

More than three-fourths of the population consists of ethnic Belorussians. As a branch of the East Slavs, mostly Eastern Orthodox in religion, the Belorussians are linguistically and culturally closely related to the Russians and Ukrainians. They have traditionally been an overwhelmingly rural people, and only since the 1980s have a majority of them resided in cities. The Russians, who form 13% of the population, are much more highly urbanized, and the Russian language has long predominated in the cities and governmental institutions. The official use of Belorussian has increased, however, since 1990, when it was declared the country's official language.

Education and Health Care

Near universal literacy was achieved in Belarus by the 1950s. Ten-year primary and secondary education is free and compulsory; higher education is free, and entrance is by competitive examination. In higher and specialized secondary education Russian predominates as the language of instruction.

The provision of medical services made dramatic advances in Belarus during the 20th century, and has been free since the early Soviet period. The quality of medical care has declined since the 1970s, however, reflected in rising infant mortality rates and a lowered life expectancy. The impact of the Chernobyl nuclear disaster on public health, though not easily measured, was undoubtedly severe.

Major cities, in addition to Minsk, are the administrative centers: BREST, Gomel (Homyel'), Grodno (Hrodna), Mogilev (Mihilyow), and Vitebsk (Vitsyebsk).

Culture

The Belorussians possess a rich folklore and a legacy of

ACADEMIC AMERICAN ENCYCLOPEDIA

BELARUS

literature, art, and architecture from the Kievan and Lithuanian periods. The 18th and 19th centuries were a time of Polish and Russian cultural ascendancy. A Belorussian literary rebirth began at the turn of the 20th century, and native cultural life was vibrant in the 1920s. Beginning in the 1930s Soviet policy favored the Russian language and culture; only in the late 1980s did Belorussian cultural life experience a new revival.

ECONOMY

Until independence Belarus was fully integrated into the centrally planned Soviet economy, in which resource allocations, production targets, and monetary policy were determined in Moscow. The economic difficulties that beset the USSR in the 1980s were reflected in Belarus and intensified after independence. Movement toward a free market system has been slow, and largely limited to the service sector. Most industry continues to be under state management and agriculture remains collectivized.

Agriculture

Livestock (cattle, hogs, sheep, and goats) accounts for more than half the value of agricultural output in Belarus. The country's chief crops are fodder and potatoes, followed by cereal grains (mainly rye, barley, and oats) and sugar beets. Industrial crops such as flax and hemp are also important.

Industry

Traditionally an agricultural land, Belarus experienced industrialization only after World War II. The country long specialized in such light industries as food processing, woodworking, and textiles; newer industries include chemicals, oil refining, instrument making, and electronics. Important products include trucks, tractors, and agricultural machinery, as well as consumer goods such as sewing machines, pianos, and watches.

GOVERNMENT

Until it formally gave up its monopoly on power in early 1990 the Communist party was the sole political party in the Soviet Union. The Communist Party of Belarus was entirely

Copyright (c) 1993 Grolier Electronic Publishing, Inc. All rights reserved.
▲PRODIGY(R) interactive personal service 06/25/93 11:57 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

BELARUS

subordinated to the central party organs in Moscow--the Central Committee and the ruling Politburo. The government of the Belorussian SSR in turn strictly implemented party policy directives. The first free and partly contested elections in Belarus were held in March 1990. The newly elected parliament though still dominated by Communist deputies, gradually asserted greater autonomy from Moscow, and in the wake of the failed Soviet coup of August 1991, declared Belarus's independence. The activities of the Communist party were then suspended, but the development of a multiparty system proceeded slowly, and former Communists maintained their leading positions in government.

According to the existing constitution, which dates to 1978, Belarus is a parliamentary republic. It has a unicameral parliament (Supreme Soviet) of 360 members. The parliament elects a presidium and chairman (president), who functions as head of state. In 1993 the president was Stanislav S. Shushkevich. Responsible to parliament is the council of ministers (cabinet), headed by a chairman (the prime minister). The council of ministers exercises the executive and administrative powers of government. The parliament also appoints the country's supreme court.

HISTORY

After centuries of Polish-Lithuanian rule, western Belarus was annexed by Russia in 1793, and eastern Belarus in 1795; together they were known as the Northwestern Provinces. Ties with Poland remained strong in the 19th century. The Polish anti-Russian uprisings of 1830 and 1863 attracted some support in Belarus, especially among the gentry. An independent Belarus was proclaimed after the collapse of the Russian Empire, while Belarus was under German-Austrian occupation (March 1918), but Polish forces moved into western Belarus the following December. In the POLISH-SOVIET WAR of 1920, Poland tried unsuccessfully to create a Polish-Belorussian federation, but the Treaty of Riga (1921) partitioned Belarus between Poland and the Soviet Union. The Polish half was retaken by

the USSR in 1939 and became part of the Belorussian SSR. An independence movement reemerged with the formation of the Belorussian Popular Front in 1988, and unrest among Belorussian workers contributed to the economic crisis that hastened the end of the USSR in 1991. The parliament of Belarus voted in early February 1993 to ratify the first Strategic Arms Reduction Treaty (START I) and to approve adherence to the

JUDAISM

{joo'-day-izm}

Judaism, the religion of the JEWS, claims over 14 million adherents throughout the world. It is the oldest living religion in the Western world. Historically, Judaism served as the matrix for Christianity and Islam, the other two great monotheistic religions, which together with Judaism claim half the world's population as adherents.

BELIEFS

Judaism was the first religion to teach MONOTHEISM, or belief in one God. This belief is the basis of Judaism and is summed up in the opening words of the Shema, recited daily: "Hear O Israel, the Lord our God, the Lord is One" (Deut. 6:4). Jews believe that God's providence extends to all people but that God entered into a special COVENANT with the ancient Israelites. They do not believe that they were chosen for any special privileges but rather to bring God's message to humanity by their example. Belief in a coming MESSIAH has been a source of optimism for Jews.

The beliefs of Judaism have never been formulated in an official creed; Judaism stresses conduct rather than doctrinal correctness. Its adherents have a considerable measure of latitude in matters of belief, especially concerning the messianic future and immortality. Judaism is a this-world religion; its objective is a just and peaceful world order on earth. This hope is assured by the belief that God is the Lord of history as well as of nature.

The basic source of Jewish belief is the Hebrew BIBLE (called the "Old Testament" by Christians), especially its first five books, called the TORAH or the Pentateuch. The Torah was traditionally regarded as the primary revelation of God and his law to humanity; it is considered as valid for all time. Its laws were clarified and elaborated in the oral Torah, or the tradition of the elders, and were eventually written down in the MISHNAH and TALMUD. Thus, Judaism did not stop developing after the Bible was completed. The traditional Jewish prayer book is an important result of this process of development, reflecting the basic beliefs of Judaism as well as changes in emphasis in response to changing conditions. During the Middle Ages, systematic codes of talmudic law were compiled. Jewish literature--legal, ethical, philosophic, mystical, and

ACADEMIC AMERICAN ENCYCLOPEDIA

JUDAISM

devotional--is virtually endless.

PRACTICES

Judaism has a system of law, known as HALACHAH, regulating civil and criminal justice, family relationships, personal ethics and manners, social responsibilities--such as help to the needy, education, and community institutions--as well as worship and other religious observances. Some laws once deemed very important, for example, laws governing the offering of sacrifice and most rules of ceremonial defilement and purification, have not been practiced since the destruction of the Second Temple in Jerusalem in AD 70.

Individual practices still widely observed include the dietary laws (see KOSHER); rules concerning the marital relationship, daily prayer, and study; and the recital of many blessings, especially before and after meals. The SABBATH and festivals are observed both in the home and in the SYNAGOGUE, a unique institution for prayer and instruction that became the model for the church in Christianity and for the mosque in Islam. Traditionally observant Jews wear tefillin, or PHYLACTERIES, on their forehead and left arm during morning prayers, and affix to their doorposts a mezuzah, a little box containing a parchment scroll inscribed with passages of the Torah that emphasize the unity of God, his providence, and the resulting

duty of serving him. In accordance with biblical law, men wear a fringed shawl (tallith) during prayer. Covering the head is a widespread custom.

The Jewish religious calendar, of Babylonian origin, consists of 12 lunar months, amounting to about 354 days. Six times in a 19-year cycle a 13th month is added to adjust the calendar to the solar year. The day is reckoned from sunset to sunset.

The Sabbath, from sunset Friday to sunset Saturday, is observed by refraining from work and by attending a synagogue service. Friday evening is marked in the home by the lighting of a lamp or candles by the woman of the household, the recital of the kiddush (a ceremonial blessing affirming the sanctity of the day) over a cup of wine, and the blessing of children by parents. The end of the Sabbath is marked by parallel ceremonies called havdalah. Similar home ceremonies occur on the festivals.

The holidays prescribed in the Torah are the two "days of awe,"

ACADEMIC AMERICAN ENCYCLOPEDIA

JUDAISM

ROSH HASHANAH (New Year) and YOM KIPPUR (Day of Atonement), and three joyous festivals, PASSOVER, SHAVUOTH (Feast of Weeks), and the Feast of TABERNACLES. Later additions are the festive occasions of CHANUKAH and PURIM, and the fast of the Ninth of Av (Tishah be-Av), commemorating the destruction of the Temple. On the 8th day after birth, male children are circumcised as a sign of the covenant with Abraham; the boy is named during the ceremony (see CIRCUMCISION). Girls are named at a synagogue service. At the age of 13, a boy is deemed responsible for performing the commandments (BAR MITZVAH). To mark his new status, the bar mitzvah takes part in the Bible readings during a synagogue service. (The synagogue service is sometimes popularly referred to as the bar mitzvah.) A similar ceremony for girls (bat mitzvah) is a recent innovation. Somewhat older is the confirmation ceremony for both sexes introduced by Reform Judaism; it is usually a class observance on or near Shavuoth.

Judaism has characteristic, but not unparalleled, customs concerning marriage and death and mourning. The importance attached to recital of the KADDISH prayer by mourners dates from the Middle Ages. The prayer itself is much older and was

originally recited as the conclusion of a sermon; it is related in thought and language to the "Lord's Prayer" of Christians. After the disasters during the First Crusade, the Jews of central and later eastern Europe introduced a memorial service on Yom Kippur and on other holidays; they also began to observe the anniversary of the death of parents.

HISTORY

In the biblical account, the patriarchs ABRAHAM, ISAAC, and JACOB received the revelation of the one, true God, who promised special protection to the Israelite tribes (of whom there were 12, descended from the 12 sons of Jacob, who was also called Israel).

Origins

Many 19th-century scholars held that monotheism gradually emerged out of POLYTHEISM, the evolution being complete only with the great prophets in the 8th century BC and later. Today many are convinced that monotheism was already a reality in the days of MOSES (13th century BC) and that later prophets developed more fully only the ethical and spiritual

▲PRODIGY(R) interactive personal service 06/25/93 11:59 PM

ACADEMIC AMERICAN ENCYCLOPEDIA

JUDAISM

implications of the belief. All the Israelite tribes agreed on the worship of one God named Yahweh (see GOD); they shared the memory of slavery in Egypt, the deliverance under Moses, and the Mosaic covenant and revelation at Sinai. Although some practices were borrowed from surrounding peoples (agricultural festivals, civil jurisprudence), the Israelite religion was kept pure of paganism through the strenuous efforts of the prophets. Unparalleled in any other Near Eastern religion are Judaism's prohibition of images, observance of the Sabbath, dietary laws, legislation guaranteeing support of the poor as a matter of right, and protection of slaves and animals against cruelty. When a loose tribal confederation was replaced by a national state under Kings SAUL and DAVID a national Temple in Jerusalem helped unify the people spiritually. After the division of the kingdom following the death (c.933) of SOLOMON, the northern kingdom of Israel also had national shrines (see ISRAEL, KINGDOM OF; JUDAH, KINGDOM OF).

Prophets

The PROPHETS exercised decisive influence on all development in Israel. From the time of the 11th-century-BC prophet Samuel, they ceased to be mere soothsayers and became more and more national leaders, speaking in the name of God (the Hebrew word for prophet is navi, meaning "spokesman"). They upheld strict principles of justice and humanity, criticizing bluntly the most powerful forces in the nation. They warned of national disaster unless a radical improvement of religious and moral standards was realized. The reform movement led by King JOSIAH (c.640-609 BC), based on the Book of DEUTERONOMY, was probably undertaken under prophetic influence; the reforms included abolishing all local shrines and sanctuaries and limiting sacrifice to the Temple in Jerusalem. This dramatized belief in one God and reduced the importance of sacrifice in the daily life of the worshiper. The gap left by the abolition of the local shrines was eventually filled by the establishment of the SYNAGOGUE, but there is no clear reference to this new institution until some four centuries later. The most mature and eloquent expression of prophetic ideals is found in the recorded speeches of the later prophets, beginning in the 8th century BC with the prophet Amos.

The Exile and Foreign Influences

The fall of both kingdoms and the BABYLONIAN CAPTIVITY (586-538

JUDAISM

BC) were perceived as a confirmation of the prophetic predictions and therefore of the truth of their message. Thus the Israelites were prepared to listen to the prophets of hope who now appeared, promising not only national restoration but also the ultimate redemption of all peoples from idolatry, injustice, and war.

Returning exiles were leaders in the revival of the Palestinian center (now confined to the area of the former southern kingdom of Judah) and the building of the Second Temple. The high priests usually served as official representatives to the Persian government and to the succeeding empires. In the middle of the 5th century BC, the final form was given to the Torah--in the opinion of many scholars, a composite of laws,

narratives, and poems dating from different periods, but with beginnings going back to Moses; and the people formally accepted the Torah as the rule for their life. Shortly thereafter the SAMARITANS broke away from the main body of Judaism; small numbers of this sect still survive.

During this period, prophecy waned and finally disappeared, but the writings of the great prophets were compiled and accepted as sacred literature. Other books were composed--notably, wisdom literature, such as JOB--and many of them were eventually included in the Bible.

Some elements of Persian religion were incorporated into Judaism: a more elaborate doctrine of ANGELS; the figure of SATAN; and a system of beliefs concerning the end of time, including a predetermined scheme of world history, a final judgment (see JUDGMENT, LAST), and the RESURRECTION of the dead. These ideas were expounded in many visionary documents called apocalypses; none of them was included in the Hebrew Bible except the Book of DANIEL (see APOCALYPSE THEME; APOCALYPTIC LITERATURE; ESCHATOLOGY).

Hellenism and Judaism

Following the conquests of Alexander the Great (d. 323 BC), Judea (as Judah came to be called) passed under the rule of Alexander's Egyptian successors (the Ptolemies) and later his Syrian successors (the Seleucids). Under these Hellenistic rulers, Jewish life was changed both inwardly and outwardly, in Palestine and in the growing DIASPORA. In Alexandria, which acquired a large Jewish population, novel forms of Judaism emerged. The Bible was translated into Greek (the SEPTUAGINT),

ACADEMIC AMERICAN ENCYCLOPEDIA

JUDAISM

the first of innumerable translations. New explanations of the Torah were devised in the 1st century AD by PHILO OF ALEXANDRIA.

The Greek language and customs also affected Palestinian Jewry; the Jewish emphasis on study may be in part the result of Greek influence. But while many Jews were attracted to pagan customs and attitudes, the majority resisted these trends. The attempt of the Seleucid king ANTIOCHUS IV to impose the Greek religion by force aroused open rebellion led by the MACCABEES, a Jewish

priestly family. During the short period of Judean independence under the Maccabees (also called Hasmoneans) a movement of proselytizing began that was apparently not organized but was nevertheless energetic. Large numbers of persons, disillusioned with the old pagan cults, adopted Judaism formally or attached themselves unofficially to the synagogue.

The Sects

The worldliness of the later Maccabees alienated most of their subjects, and effective leadership passed more and more to pious and learned laymen, especially after the Romans established control in 63 BC. These laymen formed the party of the PHARISEES (separatists); democratic in spirit, the Pharisees sought to adapt the laws of the Torah to changing needs, utilizing old popular traditions (oral Torah), which they expanded by the free method of MIDRASH, or verse-by-verse interpretation of scripture. Their opponents, the SADDUCEES, were drawn largely from the wealthy classes and from the priesthood; conservative in religious matters, the Sadducees interpreted scripture strictly, disregarding the oral tradition and popular customs, and rejecting the doctrine of resurrection. The Pharisees were followed by the majority; all subsequent Judaism was pharisaic, and the roots of Christianity and Islam are found in pharisaic Judaism. (The ESSENES were a sort of right-wing, monastic splinter group of the Pharisees; they probably wrote the DEAD SEA SCROLLS.)

Talmudic or Rabbinic Judaism

After the disastrous revolt against Rome in AD 66-70, the pharisaic leaders, whose successors bore the title RABBI, rallied the people around the synagogue and the academies of learning. Through centuries of effort (recorded in the

ACADEMIC AMERICAN ENCYCLOPEDIA

JUDAISM

Mishnah, Talmud, and many works of midrash) they produced a disciplined and loyal Jewish community.

The earliest Christians differed from other Jews chiefly in their belief that Jesus was the messiah. But under the leadership of Saint Paul and others, gentile Christianity soon

became dominant, and the break between the two religions became complete. When the Roman Empire became officially Christian in the 4th century AD, the Jews became subject to many discriminatory laws, including a prohibition against seeking or even accepting converts.

In the 4th century, religious and legal leadership was assumed more and more by the Babylonian center of learning; and from the 5th century, the Babylonian Talmud was generally accepted as the authoritative source of law. Thereafter world leadership remained with the Babylonian scholars; the heads of the academies, called Gaonim ("excellencies"), provided information and advice on legal and other questions to the Diaspora communities. In the 8th century, the sect of KARAITES broke away, rejecting tradition and rabbinic authority, and seeking to live by the letter of the biblical law. After four centuries of vigorous activity, the sect declined; today only remnants survive.

Philosophy and Mysticism

By AD 1000, the Babylonian center was in decline, but new centers of Jewish culture emerged in North Africa and in Muslim Spain. (The Spanish Jews, together with the oriental communities, came to be known as SEPHARDIM, and those of Christian Europe as ASHKENAZIM. The two groups differ somewhat in liturgical forms, in the pronunciation of Hebrew, in their music, and in many customs.) Under tolerant rulers, Jews participated actively in the Arabic cultural renaissance. In addition to commentaries on the Bible and Talmud, they also wrote extensively on grammar, science, and philosophy, usually in Arabic, and produced outstanding poetry in Hebrew, both religious and secular.

Although the first important Jewish philosopher was the Gaon SAADIA in Baghdad (10th century), nearly all of his important successors were of Spanish origin, including the preeminent MAIMONIDES. These philosophers were scholastics, like their Muslim and Christian contemporaries, drawing largely on the works of Aristotle and the Neoplatonists. Like Philo, they

ACADEMIC AMERICAN ENCYCLOPEDIA

JUDAISM

tended to explain difficult Bible passages as allegories. Their writings were welcomed by intellectuals trying to

harmonize revealed religion with the new scientific learning. But the masses were not interested in them, and many of the orthodox leaders regarded the new doctrines as subversive. After the death of Maimonides, his admirers and detractors waged a bitter struggle in Christian Spain and the Provence. His last important successor, Chisdai Crescas (d. 1410), undertook a critique of Aristotle in the interest of simple faith.

More lasting and widespread was the influence of KABBALAH ("tradition"), a term that includes various mystical doctrines and practices. Mystical elements appear in the old apocalypses and in talmudic and gaonic literature. There were mystical movements in Europe as well, culminating in the 13th and 14th centuries in southern France and northern Spain. A wealth of kabbalistic writings was produced, including the Zohar ("splendor") of Moses de Leon (13th century).

There are many kabbalistic systems. In addition to true mystical experience, they contain mythological and magical elements, reinterpretations of biblical and talmudic passages and of prayers and commandments, Neoplatonic ideas, and messianic speculations. The tragedies that befell the Jews of Spain, culminating in the expulsion of 1492, called for stronger comfort than rational philosophies could offer. This was in some measure provided by Kabbalah, with its enthralling mysteries and increasing emphasis on messianism. The Jews of central and eastern Europe also cultivated Kabbalah. These communities were unsurpassed in talmudic learning; French scholars contributed much to biblical studies also. They introduced a number of legal changes to improve the status of women including a formal ban on polygamy.

The 17th century saw a revival of Jewish life in Palestine. An attempt to revitalize the legal system by creating a new SANHEDRIN, or central court, was unsuccessful. But a 17th-century mystical revival had a profound effect on Jewish thought and liturgy. The messianic speculations of this new Kabbalah, taught by Isaac LURIA, and the massacres of Polish Jewry in 1648 formed an explosive combination; in 1665 a Turkish Jew, SABBATAI ZEVI, proclaimed himself the messiah. There had been many such messianic claimants over the centuries, but they never achieved more than a local following;

ACADEMIC AMERICAN ENCYCLOPEDIA

JUDAISM

Sabbatai's announcement, however, shook world Jewry. Thousands of believers left their homes to join him in Palestine. When Sabbatai broke under threats and accepted Islam, there was widespread disillusionment and despair. Yet a substantial number of believers kept up an underground Sabbatean movement for over a century, finding kabbalistic justifications for their leader's apostasy and awaiting his triumphant return.

A more positive mystical movement arose in eastern Europe in the 18th century. It was founded by BAAL SHEM TOV and was known as HASIDISM. Its leaders were versed in the mysteries of Kabbalah, but they addressed themselves to the unlearned masses, teaching them a simple and joyous faith and encouraging them to express their religious feelings in ecstatic song and dance. Initially opposed by the rabbinic leaders as heretical, Hasidism survived such attacks and is today regarded as representative of extreme Orthodoxy. The movement declined for a time because it fostered "the cult of personality" and encouraged superstition, but it seems to have regained vitality in some American cities and in Israel.

Modern Developments

Except for these mystic stirrings, Jewish life from the 16th to the 19th centuries--the GHETTO period--was rather torpid. But gradually modern scientific and philosophic ideas penetrated the ghetto. These influences began to be felt in the West during the 17th century. The Enlightenment of the 18th century witnessed discussion of improving the situation of Jews and led to their emancipation under the impact of the American and French revolutions. Though progress in Germanic lands was slow and disappointing, and in eastern Europe and in the Muslim lands virtually nonexistent, the impact of new ideas was felt everywhere among Jews. The Jewish community no longer provided its members with political status. Wherever Jews received citizenship, the old Jewish community lost its authority; in the New World it had never existed, and in Russia it was dissolved by government order in 1844. No longer subject to community discipline, confused by new social and intellectual conditions, Jews were uncertain of their place in the modern world.

One response was Haskalah, the Hebrew word for "Enlightenment," which sought to bring modern knowledge and ideas to large numbers of Jews, using chiefly writings in modern Hebrew.

ACADEMIC AMERICAN ENCYCLOPEDIA

JUDAISM

Moses MENDELSSOHN made the pioneer effort in 18th-century Berlin. His program--to combine modern education with strict Orthodox practice--was ineffective; his efforts led rather to assimilation, even to Christian baptism for worldly advancement. In Austrian Poland (Galicia), Haskalah was more fruitful, resulting in new efforts to study Jewish history and literature by modern critical methods ("the science of Judaism"), a trend continued with great success in Germany. In Russia, the attempt at popular education, with the slogan "Be a Jew at home and a man elsewhere," was soon recognized as futile because of the government's viciously anti-Jewish policies. In its place, a movement for Jewish nationalism arose--first expressed in secular literature in Hebrew--decades before the rise of political ZIONISM. Later a strong socialist movement developed in urban centers, and these Jewish socialists spoke in Yiddish, the folk language, rather than in Hebrew.

In the West, Enlightenment led to attempts at religious reconstruction, partly as a response to spreading indifference and apostasy that ghettoized Orthodoxy could not check. The first reforms were external, to provide a more decorous and attractive synagogue service, with portions of the service read in the language of the country, organ and choral music, and the revival of preaching. These changes aroused Orthodox opposition and sometimes government intervention. The Reformers had recourse to the newly developing "science of Judaism," showing that Judaism had always grown and changed. Eventually they developed a modernist theology, rejecting the literalist understanding of Scripture and the changeless authority of the halachah. They upheld a doctrine of progressive revelation, equating the revelation of God with the education of the Jewish people and of all humanity. They rejected the traditional prayers that asked for a return to the land of Israel and the restoration of sacrifices. Instead of a personal messiah, they envisioned a messianic age of brotherhood and peace; and instead of bodily resurrection, they taught a purely spiritual immortality. They discarded many traditional observances as no longer meaningful, modified others, and introduced new ones, such as confirmation. They also affirmed the equality of women in religious matters. A second group of modernists held similar theoretical views, but retained traditional practice with only limited modifications; they became the spiritual fathers of Conservative Judaism in the United States.

ACADEMIC AMERICAN ENCYCLOPEDIA

JUDAISM

All parties, including the Orthodox Jews in western countries, were perfervid in patriotism toward their several lands. All were deeply affected by 19th-century liberalism--optimistic, universalistic, and convinced of the reality of progress. The modernist movements, starting in Germany, had only modest success in Europe, but expanded greatly in North America. They have since acquired followers in Latin America, South Africa, Australia, and Israel. The terms Reform, Liberal, Progressive, Conservative, and Reconstructionist are used in various countries with varying shades of meaning; all designate nonorthodox versions of Jewish religion.

New forms of Jewish community and synagogue organization, mostly on a voluntary basis, emerged in the 19th century. The old rabbinic academies (Yeshivoth) confined instruction to the Talmud and its commentaries. At this time modern rabbinical seminaries were established whose students were exposed to the whole range of Jewish history and lore and were required to obtain a university degree as well. Important works were written on Jewish theology, displaying Kantian and post-Kantian influences. Completely new were trends toward a secularist understanding of Jewish life, more or less completely rejecting religion and finding a substitute in nationalistic and cultural activities.

The prevailing liberal, optimistic mood gradually cooled as official oppression and widespread hatred continued in eastern Europe while ANTI-SEMITISM also flourished in the West. Jewish thinkers exhibited an increasing sense of the tragic element in human life, in the style of existentialism. The trend toward Jewish nationalism took concrete form in the movement of Zionism. Initially opposed by many religious leaders of all parties and by the Jewish socialists, Zionism was vindicated by the march of events, culminating in the HOLOCAUST. World Jewry, despite many divisions and disagreements, is today united in concern and support for the State of Israel, which was established in 1948.

At present, because of political circumstances, rigid Orthodoxy is the only form of Judaism officially recognized in Israel,

for example, in solemnizing marriages and in military chaplaincy. But a large part of the population is remote from formal religion, and the modernist versions have difficulty making their message heard.

ACADEMIC AMERICAN ENCYCLOPEDIA

JUDAISM

A great exodus of Jews from the Soviet Union began in the 1970s and reached new heights in the early '90s. In the West, despite loss of members, mixed marriages, and a serious drop in the Jewish birthrate, religious institutions are flourishing. The number of synagogues and synagogue members increased dramatically after World War II. There has been a remarkable resurgence of Orthodoxy after a long period of decline, and modernist groups are placing greater emphasis on tradition and ceremony.

TITLE EFFECTS OF ^[[7mPATIENT^[[m ^[[7mEDUCATION^[[m AND PSYCHOSOCIAL SUPPORT

ABSTRACT:

This continuation grant is being sought to support the third phase of a project in which meta-analysis (a quantitative form of research review) will be used to summarize and analyze the effects of ^[[7mpatient^[[m ^[[7meduca tion^[[m and psychosocial support provided to adults with selected health problems. The long-term objective of this project is to increase the accessibility and usefulness of past research, on the effects of ^[[7mpatient^[[m ^[[7meducati on^[[m and psychosocial support, to clinicians, researchers, and theoreticians. The target client group in Phase I was adult surgical ^[[7mpatient^[[ms and in Phase 2 it was adults with cardiovascular health problems. In Phase 3, the target client group will be adults with other chronic health problems. The specific aims of Phase 3 are to determine: (a) the effects of ^[[7mpatient^[[m ^[[7meducation^[[m and psychosocial support on physiologic and psychologic well-being, adherence to therapeutic regimes, and knowledge about their condition among adults with selected chronic health problems; (b) the plausibility of selected threats to internal or construct validity of the review; (c) the extent to which effects are generalizable; (d) whether some types of ^[[7mpatient^[[m ^[[7meducation^[[m and psychosocial s upport are more effective than others in increasing well-being, adherence, or knowledge about their condition among adults with selected chronic health problems; and (e) the extent to which results obtained from all three phases of this project are consistent across client groups--adults surgical ^[[7mpatient^[[ms, adults with cardiovascular health problems, adults with other chronic health problems. A size-of-effect, meta-analysis of existing experimental and quasi-experimental studies on this topic will be done. It is expected that over 200 studies will be used to address Aims A through D and that over 561 studies will be used to address Aim E.

MEDICAL COLLEGE OF VIRGINIA

PO BOX 251, MCV STATION

RICHMOND, VA 23298-0251

PERFORMING ORGANIZATION: VIRGINIA COMMONWEALTH UNIVERSITY

TITLE ^[[7mPATIENT^[[m-INITIATED COMPUTER SYSTEM FOR PRIMARY CARE

ABSTRACT:

This prospective randomized controlled study will focus on the diffusion of innovation of cancer preventive services in the primary physician's practice. The intermediary organization will be the Medical College of Virginia ^[[7mEducation^[[m Sciences Center led by the Department of Family Prac tice in collaboration with the Office of Continuing ^[[7mEducation^[[m and the Massey Cancer Center. This organization has a unique history of connectedness with regional primary physicians and will collaborate with the Virginia Primary Care Association, Inc., a consortium of community health center practices, and the Virginia Insurance Reciprocal, a physician medical malpractice insurance company. Project goals include: 1. To demonstrate improved ^[[7mpatient^[[m cancer prevention for cancer of the breast, cervix, oral cavity, and colon and rectum with supporting ^[[7meducation^[[mal services as compared to control practices. 2. To diffuse the HealthTouch ^[[7mpatient^[[m-initiated computer system with supporting ^[[7meducation^[[mal services in all primary physician practices with in the geographic sphere of influence of the Medical College of Virginia Health Sciences Center. 3. To integrate the HealthTouch system into the care of all practice ^[[7mpatient^[[ms age 18 and over. 4. To integrate the HealthTouch system into the ^[[7mpatient^[[m care activities of receptionists, nurse, physician extenders, physicians and other members of the office health care team. 5. To maintain utilization of HealthTouch system as an integral part of the ^[[7mpatient^[[m care activities in the practice after the intervention period. 6. To initiate the placement of the HealthTouch system into as many primary physician practices as possible with the state of Virginia. 7. To introduce the HealthTouch system into primary physician practices in contiguous and other states by the MCV office of Continuing ^[[7mEducation^[[m i n Medicine, Department of Family Practice, and Massey Cancer Center. The study population will include non-academic fee-for-service primary physicians and community health center practices within the geographical sphere of influence of the organization. This area has demonstrated increased cancer mortality time trends as compared to the United States at large. The innovation will be the integration of the HealthTouch system with supporting ^[[7meducation^[[mal services into the existing core ^[[7mpatient^[[m care activities in the primary physician practice. The method of diffusion will include demonstrations, regular site visits, and continuing communication with the MCV primary care academic faculty and trained liaison nurses. Evaluation will include focused interviews with physician decision makers and staff, quantitative utilization studies, chart audit, lab log audit, and ^[[7mpatient^[[m telephone survey.

ABSTRACT:

^[[7mEducation^[[m Development Center, Inc. (EDC), in collaboration with Dana-Farber Cancer Institute, Harvard Community Health Plan (HCHP), and the Dartmouth School of Medicine, proposes a study of the effectiveness of a multilevel communication campaign to improve identification, treatment, and support for women and men who are at risk of the health consequences associated with exposure to diethylstilbestrol (DES). We will compare the impact of low-intensity and high-intensity interventions in ensuring DES services for all potentially exposed individuals in Massachusetts, which has one of the highest prevalence of DES exposure in the nation. Over 36 months, we will: 1. Design and implement a low-intensity public ^[[7meducation^[[m intervention to increase knowledge about the DES risk factors and the health consequences of DES exposure to identify individuals currently unaware of their exposure, increasing DES screening, and increasing referral of those with identified DES-related health problems to treatment and support services. 2. Design and implement a low-intensity provider ^[[7meducation^[[m interventio n to increase DES-related knowledge and compliance with NCI-recommended screening and treatment protocols among physicians, nurses, and ancillary medical personnel. 3. Design video- and audiotape-based CME/CEU programs which are tailored to meet the informational needs and practice demands of physicians and nurses who should provide DES-related screening, treatment, and support services. 4. Conduct a randomized clinical trial in 14 HCHP sites comparing two levels of DES public and provider ^[[7meducation^[[m: (a) low-intensity public a nd provider ^[[7meducation^[[m interventions and (b) high-intensity combined CME/CE U, office management, and ^[[7mpatient^[[m ^[[7meducation^[[m interventions. 5. Assess the effectiveness of low-intensity and high-intensity interventions in terms of impact on improved public, provider, and ^[[7mpatient^[[m knowledge about the health risks and consequences of DES; increases in the proportion of women and men in target groups who have been screened for DES; increases in the number of DES-exposed individuals identified in the medical record; and increased adherence to NCI- recommended DES screening, follow-up, and treatment procedures. 6. Disseminate CME/CEU programs to providers in office, group, and hospital practices throughout our region and continue public ^[[7meducation^[[m outreach. Working with DES Action, the DES Cancer Network, and the DES Sons, as well as the massachusetts Medical Society, nursing associations, and local chapters of specialty practice groups, we will design and evaluate ^[[7meducation^[[mal interventions that reach the public, providers, and ^[[7mpa tient^[[ms.

FY 94 ROMANO, JOAN M
UNIVERSITY OF WASHINGTON

SEATTLE, WA 98195

PERFORMING ORGANIZATION: UNIVERSITY OF WASHINGTON

TITLE CHRONIC PAIN ^[[7mpatient^[[m-SPOUSE BEHAVIORAL INTERACTIONS

ABSTRACT:

Chronic pain represents a major U.S. health care problem, resulting in significant ^[[7mpatient^[[m and family suffering as well as costs estimated at \$79 billion annually. The refractory nature of chronic pain problems has led to the examination of psychological, behavioral, and environmental factors that could be important influences on ^[[7mpatient^[[m disability. Operant theory, supported by data from self-report studies, suggests that spouse responses to ^[[7mpatient^[[m pain behaviors may contribute to the maintenance of pain behaviors and disability. However, no studies other than the previously funded research by these investigators have examined this proposition using direct observation and sequential data analytic methods. The broad, longterm objectives of the proposed research are to examine how ^[[7mpatient^[[m-spouse interactions are related to ^[[7mpatient^[[m functioning over time, and whether long-term changes in ^[[7mpatient^[[m functioning can be predicted by pre- or posttreatment ^[[7mpatient^[[m-spouse interactions. Specifically, this study will examine the extent to which observed ^[[7mpatient^[[m-spouse behavioral interactions are associated with ^[[7mpatient^[[m disability pre- and postmultidisciplinary pain treatment and at 6-month follow-up assessment. Further, we will investigate the role that three potentially important variables may play in these relationships: ^[[7mpatient^[[m depression, gender, and marital satisfaction. Finally, the proposed research will attempt to replicate in a larger sample of pain ^[[7mpatient^[[m couples findings from the previous funding period regarding the reliability and validity of the revised LIFE coding system and the identification of sequential patterns of ^[[7mpatient^[[m pain behavior and spouse solicitous behavior. At each assessment, couples will be videotaped while performing a series of common household tasks validated in prior research. These videotapes will be scored using a system for coding sequential patterns of ^[[7mpatient^[[m and spouse behaviors. ^[[7mPatient^[[m and spouse self-report measures of functional disability, pain behaviors and associated spouse responses, depression, and marital satisfaction will also be obtained. The results of this study may pave the way for the reliable identification of ^[[7mpatient^[[m couples most in need of intervention focused on changing ^[[7mpatient^[[m-spouse interactions and the development of treatments aimed at altering spouse behaviors contributing to ^[[7mpatient^[[m disability.

TITLE VARIATION IN PHYSICIAN AND ^[[7mpatient^[[m USE OF MAMMOGRAPHY

ABSTRACT:

Variation in the use of screening mammography guidelines has been widely reported. It is clear, even considering the most recently available and optimistic utilization data, that there is a wide disparity between these data and the NCI Year 2000 goals for mammography screening rates. Variability has been explained primarily by the physicians' under-referring of certain "special populations" such as minorities and the elderly. This Project will examine whether physicians' characteristics, e.g., specialty, and patient characteristics, e.g., race, contribute to the effectiveness of physician education in achieving a completed mammography referral. The core study hypotheses are: 1) that primary care physicians' decision to refer is influenced by patient characteristics such as race, language and health insurance status, and 2) that minority, Spanish-speaking and low income women are significantly less likely than other female patients to perceive their physicians as being enthusiastic about mammography during physician education sessions. This is a prospective cohort study to determine the relationship between primary care physicians' characteristics, their patient characteristics, and the physician-patient process regarding screening mammography. Extensive data collection will occur using a sample of primary care physicians stratified by specialty, and a linked cohort sample of their patients, with validation of the medical outcome, a completed mammogram through radiology facility records. These data will allow physician-level and patient-level analyses on the relationships between physicians' characteristics and behavior, patient characteristics and their perceptions about their physician's behavior, and compliance with screening guidelines. This Project will provide insight into the role of physician education in limiting access to screening mammography among minority and underscreened women. In addition, the Project will add to our understanding of the importance of explicitly accounting for a physician's specialty and other characteristics when developing effective guideline dissemination strategies.

ABSTRACT:

There is a critical need to improve the skills of non specialist physicians who see children with asthma. Both under treatment and lack of effective patient education by physicians are cited as reasons that asthma related problems are on the increase. The purpose of this study is to test the effectiveness of an educational intervention based on self-regulation theory in changing diagnosis and treatment patterns and educational behavior of non specialist pediatricians who treat children with asthma. It is hypothesized that

^[[7meducation^[m for physicians, based o n the principle of self-regulation provided through an interactive seminar, will be effective in changing physicians' clinical behavior and improving their performance as health educators and counselors. We will also assess the effects of ^[[7meducation^[m for pediatricians on the self-managemen t behavior, health status, and health care utilization of their ^[[7mpatient^[ms. A true experimental design involving 52 physicians and 468 parent-child pairs from their practices will be utilized. A team of researchers from the University of Michigan and Columbia University will carry out the study in the Ann Arbor, Michigan and Metropolitan New York areas. The study is unique in that it is the first evaluation research to focus on pediatricians who treat asthma and to apply theories of self-regulation of behavior to physician ^[[7meducation^[m. It is one of few to use changes in ^[[7mpatient^[m self-management behavior and health care use as outcomes of physician ^[[7meducation^[m.

| TITLE CANCER CENTER OUTREACH ^[[7mEDUCATION^[m PROGRAMS | | |

ABSTRACT:

The long-term goal of this proposed program is to facilitate cancer ^[[7meducation^[m outreach programs in the Rocky Mountain region which will result in a self-sustaining community-based continuing ^[[7meducation^[m system directed both at health care professionals and lay groups. The specific aims of the proposed program include assessments of cancer ^[[7meducation^[m needs in the region, which involve a collaborative effort between the University of Colorado Cancer Center, the University of New Mexico Cancer Center, and the combined input of the Wyoming Department of Health and the Wyoming Medical Society. A centralized clearing house for developing and coordinating cancer ^[[7meducation^[m seminars, workshops, and short course s is available at the University of Colorado Cancer Center, the eligible applicant for this grant program. Outreach ^[[7meducation^[m activities will b e planned and coordinated to minimize costs and provide the optimal availability of activities to potential participants and to encourage the active participation of local health care professionals and lay leaders so they may continue the activities after the period of the grant funding. Cities in Colorado, New Mexico, and Wyoming have been grouped so outreach ^[[7meducation^[m teams can visit two or three cities during one trip. A multidisciplinary Advisory Subcommittee has been organized to assist in choosing sites, topics, and presenters. Schedules will be developed which allow contact between the outreach ^[[7meducation^[m teams and both professional and lay groups during one or two highly coordinated days. Preparatory seminars for presenters, and assistance with

slides and handouts will be coordinated by two ^[[7meducation^[[m experts on the project staff. An ongoing monitoring and evaluation program will be conducted to ensure continual evolution of the program, seeking to maintain an emphasis on cancer prevention. A second project in the program involves the production of verbatim excerpts from PDQ, the NCI cancer prognosis and treatment database. Termed PDQ in Brief, these will provide primary care physicians and nurses with readable, current information which will be distributed at no cost with the Rocky Mountain Cancer News, a bi-monthly publication of the Rocky Mountain Cancer Information Service, which is mailed to all physicians and many nurses in Colorado, New Mexico, and Wyoming.

TITLE PUBLIC ^[[7mEDUCATION^[[m CAMPAIGN SUPPORT

ABSTRACT:

The National Heart, Lung, and Blood Institute coordinates several national ^[[7meducation^[[m programs. Each of NHLBI's nationally-focused programs (high blood pressure, cholesterol, blood resource, asthma, heart attack alert, obesity) plan, coordinate, and implement comprehensive efforts in professional, ^[[7mpatient^[[m and public ^[[7meducation^[[m. These nationally- focused programs are operated in cooperation with the major national voluntary and professional organizations concerned with each health area. Mass media campaigns have played an important role in the ^[[7meducation^[[mal efforts. The purpose of this contract is to provide for the planning and development of mass media communications activities and products in support of the public ^[[7meducation^[[m goals of all of NHLBI's ^[[7meducation^[[m prog rams. Specifically, this statement of work requires the contractor provide mass media support for high blood pressure, cholesterol, blood resources, including bone marrow, asthma, heart attack alert, and obesity ^[[7meducation^[[m. The contractor shall provide the necessary personnel, facilities, services, equipment, supplies, and administrative support not otherwise furnished by the Government to plan, develop, distribute, and evaluate radio, television, and print public service announcements, arrange for travel and per diem for participants to NHLBI meetings, conduct and/or obtain research, and develop and test new mass media vehicles to reach NHLBI target audiences with health messages.

TITLE COMPUTER GAME FOR DIABETES ^[[7mEDUCATION^[m

ABSTRACT:

This proposal seeks support to develop and study an ^[[7meducation^[mal video g ame for children with diabetes. Diabetes is managed largely by ^[[7mpatient^[ms themselves; ^[[7mpatient^[m knowledge and attitude are critical to the success of treatment. Phase I established the feasibility of using a computer game to teach children about diabetes. Concurrently, a prototype game was designed for a popular home-based video game system. Phase II will expand this prototype into a commercial quality ^[[7meducation^[mal video game and study it s efficacy in diabetes ^[[7meducation^[m in a controlled trial. Children with diabetes, age 10 to 14, will receive the video game to use at home for two months. Researchers will measure subject's knowledge of diabetes, attitudes, self-efficacy, behavior and metabolic control using pre-tests, post-tests and a six-month follow-up. The results will be compared with ^[[7mpatient^[ms not receiving the intervention. As a check on the measures, t he game cartridges will unobtrusively measure usage and the players' ability to master the diabetes-based game strategy. The researchers hypothesize that a properly designed ^[[7meducation^[mal intervention, when combined with intrinsic motivations of entertainment quality video games, could lead to significant improvements in the knowledge, attitudes, self-efficacy, behavior and metabolic control of children with diabetes.

TITLE CANCER SCREENING ^[[7mEDUCATION^[m FOR OLDER MINORITY ADULTS

ABSTRACT:

The overall objective of this proposal is to improve cancer morbidity and mortality in older, low income, minority adults from Cuyahoga County, Ohio by implementation of a series of ^[[7meducation^[mal interventions amongst health care professionals, religious leaders and community members to improve the knowledge, attitudes and practices regarding utilization and participation in cancer prevention, screening, early detection and treatment programs. This goal will be accomplished by implementation of the following specific aims: 1. A community derived, peer educator based cancer prevention program, already shown to be successful for improving utilization of screening mammography in older, low income, minority women, will be further developed and extended to improve utilization of screening programs for breast, prostate and colorectal cancer and to foster more widespread use of

cancer prevention practices in the target community. 2. Formal ^[[7meducation^[m conferences will be developed and implemented to inform minority physicians, health care professionals and influential community members such as religious leaders as to the need for appropriate practices of cancer screening and benefits of early detection programs for older, minority adults. 3. A Cancer-Outreach ^[[7mEducation^[m Nurse Specialist Program will be develop ed to provide on-site, office based, ^[[7meducation^[m for physicians and other health care professionals to encourage improvement and incorporation of cancer screening and detection procedures at private and community facilities providing health care to older, minority adults. 4. A Minority Community Based Advisory Board will be formally constituted to focus on reduction of cancer morbidity and mortality in the older, low income, minority community and to evaluate and advise on further development and utilization of the programs outlined in the first three specific aims above.

TITLE HEALTH ^[[7mEDUCATION^[m PROGRAM FOR DIABETIC EYE DISEASE

ABSTRACT:

This application proposes to develop, implement, and evaluate a comprehensive culture-specific and community-based ^[[7meducation^[m program fo r the prevention of eye disease in diabetic Oklahoma Indians. The overall objectives are to increase awareness and knowledge of diabetic eye disease and to improve health behavior and health-care seeking practice in order to prevent or reduce visual impairment and vision loss. The specific aims are: (1) To assess the current knowledge and awareness of diabetic eye disease in the diabetic Oklahoma Indian ^[[7mpatient^[ms in relation to cultural, socioeconomic, and access factors. (2) Using a multi-disciplinary and multi-institutional approach to develop culture-specific comprehensive ^[[7meducation^[mal materials, including clinica l and epidemiologic information and basic science principles, for the prevention of eye disease. (3) To disseminate the ^[[7meducation^[mal materials developed through a community outreach program with family, tribal, and community support. (4) Through this comprehensive ^[[7meducation^[m program, to improve the attitudes of diabetic ^[[7mpatient^[ms toward prevention of and intervention for diabetic eye disease and consequently improve the health-care seeking practices of these ^[[7mpatient^[ms. (5) To evaluate the comprehensive ^[[7meducation^[m program for its short-term effectiveness and compare it to a more traditional method of information dissemination. In addition, we will investigate cost-effective methods for facilitating access to comprehensive eye examination by primary health care providers and subsequent referral for evaluation and treatment by an ophthalmologist when indicated. The study population will be Native Americans who reside in southwestern Oklahoma. The rates of diabetes in this group have reached epidemic proportions. Available data also indicate high incidence and prevalence of eye

PERFORMING ORGANIZATION: BAYLOR COLLEGE OF MEDICINE
TITLE NATIONAL DES ^[[7MEDUCATION^[[m PROGRAM

ABSTRACT:

The purpose of this study is to document barriers and test strategies with a replicable model to improve the appropriate identification, diagnosis, and treatment of DES-associated medical conditions. The specific aims of this study are: 1) to identify potentially DES-exposed women and offspring in addition to those already registered in the DESAD project; 2) to reach health providers and the DES-exposed population in a cost effective strategy to disseminate the most current information about DES exposure sequelae and treatment; and, 3) to provide clinical and ^[[7meducation^[[mal consultation to physicians, nurses and DES-exposed women and their children through an expansion of previous efforts with the establishment of the Southwest Regional DES Clinical Center. A behavioral model by Prochaska & DiClemente is utilized in this study which presumes that all persons are not at the same point of adopting a specific health-related practice, such as surveillance and treatment of DES exposure. This theoretical model will facilitate the interpretation of the effect of a health communication intervention with two population targets: health providers and DES-exposed women in the state of Texas. Several methods will be used including specific sampling techniques to identify the exposed population; ^[[7meducation^[[m with multi-media and other schema; measurement of health practices in the exposed population and readiness to act on germane DES information; and, identification and ^[[7meducation^[[m of health providers. These methods are cost effective and efficient, utilizing existing professional organizations and print/television media to promulgate specific health information to improve identification of potential DES-exposed women and their offspring and health providers.

PERFORMING ORGANIZATION: STANFORD UNIVERSITY
TITLE HUMAN GENOME PROJECT ^[[7MEDUCATION^[[m OUTREACH

ABSTRACT:

With its applications for genetic screening and recombinant pharmaceuticals, and its potential for use in gene therapy, the information obtained by the Genome Project will have a profound impact on public health. The long-term objective of this grant is to help enable the general public in San Francisco to make educated decisions on the personal, ethical, and social questions raised by the work of the Genome Project in medicine and other areas that will affect their lives. This objective will be

achieved by an ^[[7meducation^[mal outreach program designed to provide the public with a basic, working understanding of the science behind, applications of, and ethical issues raised by the Genome Project. The ^[[7meducation^[mal program consists of four specific aims. The first aim is to develop and present in high school classrooms a curriculum consisting of laboratory experiments and "dry-lab" exercises using three-dimensional models that addresses the ^[[7meducation^[mal goals described above. The second aim is to reach members of the public outside the high schools by developing interactive exhibits and laboratory demonstrations about the Genome Project for use in a "hands-on" public science museum, The Exploratorium. The third aim is to increase the depth and range of public understanding of Genome Project-related subjects by providing lectures and discussions on a variety of topics of interest to groups including genetic disease support organizations, adult ^[[7meducation^[m classes, and high school and junior college students. The fourth aim is to demystify scientific research by bringing members of the general public into a working laboratory to talk with Genome Project scientists and to manipulate laboratory equipment in an interactive tour of the Human Genome Mapping Center at the University of California, San Francisco.

| TITLE COMMUNITY BASED ASTHMA ^[[7mEDUCATION^[m FOR LATINO CHILDREN | | |

ABSTRACT:

This study proposes to use a quasi-experimental design (time series) to examine the effects of a community organization and health ^[[7meducation^[m model designed to empower Latino parents to develop a coaliti on to 1) work with a local Health Department and community agencies to implement a community based program to improve the care of children with asthma and 2) to assure that their children with asthma have access to an ^[[7meducation^[mal self-management program demonstrated to have a significant impact on their children's asthma (in terms of reductions in hospitalizations and emergency room visits). The design incorporates this child-centered, family-focused intervention for children with asthma (ACT Para Los Ninos) within an overall community organization intervention. The impact of ACT on the children/families will be assessed in a one year pre-/post-comparison of outcome measures. The impact of the community organization intervention will be assessed by comparing community asthma-related activities in the experimental community to a comparison community. Children/families with asthma will be identified in both communities (N-450) and serve as sources of information on levels of community activity/concerns (to be verified) over the course of the study. In the experimental community, 150 children will participate in the ACT program. Data will be collected pre-intervention and post-intervention on children receiving ACT, and a comparison group (N-300) in a community un-involved in organizing efforts. Children's measures include knowledge and attitudes related to care, self-esteem,

TITLE COMPUTER ^[[7mEDUCATION^[[m AND RISK ASSESSMENT FOR HIV INFECTION

This project is to support the continued testing, validation, and refinement of computer software for personal anonymous risk assessment for HIV infection. The software, originally developed as a stand-alone microcomputer system, performs a detailed interview in privacy. Personal sexual history data provided by the respondent is analyzed by the software's expert system which incorporates probability computation supported by databases consisting of local estimates of HIV infection and per-event infectivity specific to vaginal and anal intercourse. The software also interviews respondents and assesses risk on the basis of personal intravenous drug abuse and blood transfusion history. The software advises respondents as to whether their past experience places them at risk for HIV infection. If so, they are advised to follow up with antibody tests. Users not at risk are cautioned to avoid risk of exposure to HIV. The interactive interview is preceded by a sequence of educational screens. Additionally, the software writes anonymous interview data to disk file for statistical analysis in support of health behavior research. The software was tested in a preliminary study which yielded publication. Continued research was supported by a Phase I SBIR grant. For a Phase II project, several new tasks are proposed and presented in the research plan.

IMPROVING PHYSICIAN MANAGEMENT OF ALC

FY 92

BUCHSBAUM, DAVID G

UNIVERSITY OF COLORADO

CAMPUS BOX 447

BOULDER, CO 80309-0447

TITLE IMPROVING PHYSICIAN MANAGEMENT OF ALCOHOL DISORDERS

This application proposes a project that will improve primary care practitioners' recognition and management of ^[[7mpatient^[[7ms with alcohol dependence and abuse

and improve the outcomes of patients diagnosed with these disorders. After their participation in a series of medical workshops on alcoholism, all 30 first year internal medicine trainees practicing in the Primary Care Associates Group practice at the Medical College of Virginia will be randomly assigned to either an intervention group that will receive feedback on their patients diagnosed as alcoholic by DSM III-R criteria using the Diagnostic Interview Schedule (DIS) or a control group that will receive no such feedback. The feedback will include the patient's diagnosis, symptom criteria upon which the diagnosis is based and recency of last reported symptom, reported estimate of alcohol consumed per week and recency of last reported drink and guidelines for the patient's management. Physician recognition and management of patients diagnosed with dependence or abuse will be evaluated during a 12 month period of feedback and for six months after cessation of feedback in the following manner: Post visit interviews to assess degree of intervention, medical record review for physician recording of alcohol problems and their management, frequency of patient referral to a clinic based rehabilitation counselor and scores on a structured substance abuse attitude survey modified for alcoholism. Statistical analysis will be applied to any differences in measures of attitudes and clinical performance between the feedback group of physicians and the control group of physicians. The effectiveness of physician intervention on patient outcome will be statistically analyzed using the following variables: Duration of symptom free interval on retest with the DIS, quantity of alcohol consumed, functional status as measured by the Sickness Impact Profile, patient health service utilization, and Gamma Glutamyl Transpeptidase enzyme activity.

ABSTRACT:

There is substantial evidence that blood cholesterol levels are causally related to the development and progression of coronary heart disease (CHD), and that alteration of cholesterol and lipoprotein levels can alter the clinical course of CHD. In 1984 the National Institutes of Health Consensus Development Conference reviewed the accumulated literature, and concluded that both population-based and patient-based approaches to lowering blood cholesterol levels were appropriate. Following the Consensus Conference report the National Cholesterol Education Program was developed, and an expert panel developed guidelines for screening and treatment. Dietary therapy is recommended for all adults with a blood cholesterol level >200 mg/dl; further classification and treatment is based on total cholesterol level; lipoprotein analysis; and risk factors. A series of algorithms guide the clinician to further dietary intervention, retesting, and

LA Eng

AB A new semianalytical method to calculate the proximity function for
electrons is proposed. An integral equation for the proximity function
that can be solved by using information on the spatial dose
distributions is obtained. The proximity function for electrons in the
energy range from 10 eV to 10 keV is calculated by solving the equation
numerically, using a set of electron collision cross sections for water
vapor. The results are in good agreement with those obtained using the
Monte Carlo method. The proposed method can be used for electrons of
high energies much more efficiently than the Monte Carlo method.

AB Associations of smoking habit with serum levels of total protein as well as protein fractions were studied in a population consisting of 4,739 atomic-bomb survivors and unexposed control subjects in Hiroshima, Japan who participated in the 1979-1981 period of the Adult Health Study, an

ongoing health follow-up program of the Radiation Effects Research Foundation. Smoking was strongly related to serum protein concentration after correction for age, sex, and body mass index. Among current smokers, levels of total protein, beta globulin, and gamma globulin were significantly lower and levels of alpha-1 and alpha-2 globulin were significantly higher, when compared with nonsmokers. For serum albumin levels a decrease was also noted, but it failed to attain statistical significance. Ex-smokers were indistinguishable from nonsmokers in terms of the serum protein levels analyzed. With an increase of the amount of daily cigarette consumption, monotonic increases of serum levels were observed only in alpha-1 globulin. Duration of smoking was related to increased alpha-1 and alpha-2 globulin. Smoking duration was also associated with albumin level, but the trend was not monotonic. The radiation exposure effect on serum protein level was significant in several instances but was in general much smaller than the smoking effect, and its inclusion in the regression models did not noticeably affect the association between smoking and serum proteins.

AB Among the costs of technology are health hazards that face employees and consumers. New advances in the highly competitive field of microelectronics involve exposure to a variety of hazards such as gallium arsenide. Small high-technology industries appear unprepared to invest in health and safety. Although stray electromagnetic fields are not a new development, researchers are beginning to assemble data indicating that such fields pose a significant cancer risk under certain circumstances. Data have been obtained on fields associated with power lines on the one hand and consumer products on the other. Although not conclusive, the data are sufficient to warrant carefully designed research into the risks posed by electromagnetic fields. Because the scientific issues require research, there is a need to make basic social value decisions that will determine which technologies will be developed and which ones may be set aside because of their danger at the present time.

 TI Auger electron emitters: insights gained from in vitro experiments.
 SO Radiat Environ Biophys 1990;29(2):75-91
 JT RADIATION AND ENVIRONMENTAL BIOPHYSICS
 AD Shields Warren Radiation Laboratory, Department of Radiology, Harvard
 Medical School, Boston, MA 02115.
 LA Eng
 AB This paper outlines the evolution of the current rationale for research
 into the biological effects of tissue-incorporated Auger electron
 emitters. The first section is a brief review of the research conducted
 by several groups in the last fifteen years. The second section
 describes the in vitro model used in our studies, dosimetric
 calculations, experimental techniques and recent findings. The third
 section focuses on the use of Auger electron emitters as in vitro
 microprobes for the investigation of the radiosensitivity of distinct
 subcellular components. Examination of the biological effects of the
 Auger electron emitter 125I located in different cellular compartments

of a single cell line (V 79 hamster lung fibroblast) verifies that DNA is the critical cell structure for radiation damage and that the sensitive sites are of nanometer dimensions. The data from incorporation of several Auger electron emitters at the same location within DNA suggest that there are no saturation effects from the decay of these isotopes (i.e. all the emitted energy is biologically effective) and provide some insight into which of the numerous physical mechanisms accompanying the Auger decay are most important in causing cell damage. Finally the implications of Auger electron emission for radiotherapy and radiation protection in diagnostic nuclear medicine are detailed and further research possibilities are suggested.

SO Biull Eksp Biol Med 1990 Jul;110(7):29-30
JT BIULLETEN EKSPERIMENTALNOI BIOLOGII I MEDITSINY
LA Rus For
AB The authors studied medullary glucosaminoglycans of rats and mice in extreme effects (hypoxia, hyperbaric oxygenation, inflammation, radiation, cooling, hemorrhage). Four types of reaction were determined which cause different changes of proliferation of hematopoietic cells. Hematopoiesis stimulation is accompanied by regular change of types of reaction of hematopoietic microenvironment. Its disturbance affects the changes of hematopoiesis and blood regeneration rate. It was shown that the increase of neutral glucosaminoglycans concentrations in bone marrow depended on the play ground and proliferative activity of erythroid sprout and that of acid glucosaminoglycans--primarily of granulocytic sprout.

TI Comparison of isoeffect relationships in radiotherapy.
SO Bull Math Biol 1990;52(5):657-75
JT BULLETIN OF MATHEMATICAL BIOLOGY
AD Department of Biometry, Medical University of South Carolina, Charleston 29425.
LA Eng
AB Irradiation affects numerous physiological processes within cells and tissues and can lead to damage or death. If the damage is not too severe, cells have the ability to repair and regenerate. Many small injuries are repaired more easily than ones causing extensive damage and, consequently, tissues typically respond differently to one large dose of radiation than to many small doses, separated in time. In the radiotherapy of tumors, the choice of the fractionation regimen of dose over time is therefore as crucial as the total radiation dose. The interdependence between total dose, fractionation regimen, and radiation effect has been described mathematically with various isoeffect relationships. These relationships appear to be fundamentally distinct and have been considered unrelated; some even claim that one class of isoeffect relationships is appropriate whereas other relationships are rather useless. We examine how alternative isoeffect models relate to each other and test the reliability of estimating parameter values of one model from the other.

TI [The functional efficiency of cardiac pacemakers as affected by ionizing radiation]
SO Radiobiol Radiother (Berl) 1990;31(4):341-50
JT RADIOBIOLOGIA, RADIOTHERAPIA
AD Strahlentherapieabteilung, Medizinische Akademie Carl Gustav Carus, Dresden.

LA Ger For

AB Influence of functions of cardiac pace-makers by ionizing radiation are represented, that is characterized in praxis relevant parameters as pulse duration and sensitivity in a special clear manner. For these parameters dose limits were defined in a phantom where tolerance ranges of pace-makers, guaranteed by producer, were over or underdosed. These dose values were different in dependence of installed electronic wiring diagrams. The radioresistance of pace-makers with Lewicki-wiring diagram (MCP 211 L) was higher than those with wiring diagram U 115. Measurements showed that the upper dose limits were greater than the known values with 60Co- and 9-MV-roentgen braking radiation and with that the complete programming and functional capacity of the pace-makers were conserved. The close cooperation of radiologists, physicists, cardiologists and technicians in the implantation clinic guarantees a good care for patients with pace-makers during radiotherapy without complications.

AB Data are reported on the possible mechanism of biological effects of small doses of ionizing radiation on the human body. The lesioning effect of this radiation resulted in some of the persons in the development of disorders of the function of information and vegetative-regulatory systems determined as a disintegration syndrome. This syndrome is manifested in unspecific neuro-vegetative disorders of the function of most important physiological and homeostatic system of the body leading to weakening of the processes of compensation and adaptation. This condition is characterized by an unspecific radiation syndrome as distinct from acute or chronic radiation disease which is a specific radiation syndrome.

TI Effects of long-term radiation exposure on chromosomal aberrations in radiological technologists.

SO J Radiat Res (Tokyo) 1990 Sep;31(3):270-9

JT JOURNAL OF RADIATION RESEARCH

AD Department of Medical Technology, Kumamoto University College of Medical Science, Japan.

LA Eng

AB Chromosomal aberrations in the lymphocytes of radiation technologists (RT) were analyzed by the trypsin G-banding method to study the late effects of long-term exposure to low doses of radiation. Structural aberrations were identified in 384 (2.5%) of 15,442 cells analyzed from 53 RT as compared to 177 (1.6%) of 11,136 cells from 36 healthy controls. Stable aberrations were the most frequent in both groups and were either translocations or deletions. Unstable aberrations were mainly acentric fragments in both groups. The frequency of translocations and acentric fragments was significantly higher in the RT than in the controls and was highest in the RT over 50 years. The highest frequency observed in the greater than 50 age group was attributed to the unknown for cumulative dose prior to introduction of film badges. Frequency of chromosomal aberrations correlated with the estimated dose from the film badges and years of experience of each RT based on the equation $y = 0.22 + 0.37D + 4.35D^2$, where y is overall frequency of chromosomal aberrations and D is the estimated radiation dose in Sv.

 JT CRITICAL REVIEWS IN ONCOLOGY/HEMATOLOGY
 AD Department of Radiation Oncology, Johns Hopkins Hospital, Baltimore, Maryland 21205.
 LA Eng
 AB Unexpected total body irradiation (TBI) of human beings, involved in nuclear warfare or in accidents in nuclear reactors can be lethal. In the 1950s, bone marrow transplantation was discovered as a potentially life saving procedure after TBI in the dose range of 5.0 to 12.0 Gy. Since that time, deliberate or "therapeutic" TBI has been used to condition patients with a lethal bone marrow disorder for bone marrow replacement. The therapeutic ratio of TBI followed by bone marrow transplantation is small. Many potentially lethal complications can occur, such as acute TBI side effects, late TBI side effects or immunological complications of bone marrow transplantation such as graft versus host disease or graft rejection. The benefits of TBI and bone marrow transplantation are that they offer a chance for cure of previously lethal bone marrow disorders. The optimal parameters for TBI remain to be defined. The review discusses the current clinical and experimental animal data, as they relate to the future definition of less toxic TBI procedures with a better therapeutic ratio. Different TBI procedures are required for patients with malignant vs. non-malignant disorders or for patients with histoincompatible vs. histocompatible bone marrow donors.

AB Fundamental to evolutionary biology is the tendency for organisms to become progressively adapted to those environments to which they are most frequently exposed. Since background radiation is a universal component of our environment, radiation hormesis is an evolutionary expectation. Whole-of-life experiments and more numerous (and evolutionarily more artificial) shorter duration and higher dose-rate experiments are consistent with this expectation. Additional research is needed especially at the molecular level to search for underlying mechanisms, and implications for radiation protection guidelines need to be analyzed.

 AB Bacterial infection of simple wounds was studied directly and quantitatively in adult mice given 6.5 Gy ⁶⁰Co. Three days later, when neutropenia was evident, the skin and the medial gluteus muscle of anaesthetized mice were incised. A suspension of Staphylococcus aureus, Escherichia coli, Klebsiella pneumoniae or Streptococcus pyogenes was inoculated into the wound. Bacteria per mg muscle were enumerated 3, 4 or 7 days later. The geometric means of bacteria per mg were greater in irradiated than in non-irradiated mice. Phagocytic cells were present in the wounded tissue. Hence sublethal ionizing radiation enhanced the susceptibility of mice to infections of wounds by these four bacterial species.

SO J Nucl Med 1991 Feb;32(2):350-9
JT JOURNAL OF NUCLEAR MEDICINE
AD Dept. of Radiation Therapy, Harvard Medical School, Boston, MA 02115.
LA Eng
AB "Radiation hormesis" is the name given to the putative stimulatory effects of low level ionizing radiation (generally in the range of 1-50 cGy of low-LET radiation). Based on historical and pharmacologic principles reminiscent of some of the major tenets of homeopathy, most of these effects are now generally ascribed to protective feedback systems that, upon exposure to low concentrations of toxins, proceed to stimulate metabolic detoxification and repair networks. The activation of these networks may then result in net beneficial effects on the cell, organism or species. Discussions of possible stimulatory effects of low levels of ionizing radiation have recently become entangled with the separate but related question of whether a threshold dose level exists on the radiotoxicologic dose-response curve. This review summarizes some of the relevant historical and scientific data bearing on the question of radiation hormesis. We find the data in support of most of the hormesis postulates intriguing but inconclusive.

TI [Calculation of the radiation-induced delay in cell division during a study of the induction of chromosome aberrations (the theoretical and experimental bases of the approach)]
SO Radiobiologiya 1991 Jan-Feb;31(1):59-64
JT RADIOBIOLOGIIA
LA Rus For
AB The possible influence of a radiation-induced delay of cell division on the yield of chromosome aberrations has been analyzed theoretically. The analysis is based on the assumption that the delay is caused by the damages that are realized in the mitosis as chromosome aberrations. It has been shown that the distributions of cells, that are registered by the number of chromosome aberrations, are a function of time of cell fixation and may substantially differ from actual disturbance. There is a correlation between the registered and actual disturbances which is determined by the kinetics of the first mitosis of nonirradiated cells and the degree of the radiation-induced division delay. Some qualitative sequels of the proposed model are in agreement with the experimental data.

- LA Eng
- AB There are several limitations to the low-temperature techniques which are currently being used for the preparation, examination and analysis of biological and organic samples by means of high-energy beam instrumentation. The low thermal conductivity of samples and the inadequacy of rapid cooling techniques means that, with the exception of thin-film suspensions and the surface of impact-cooled bulk specimens which may be vitrified, ice crystals of varying sizes will be present in nearly all samples which are quench cooled. Data are presented which indicate the depth to which adequate cryo-fixation may be achieved for both morphological and analytical studies. Although dynamic processes may be time resolved in the outer parts of quench-cooled samples, the decreased freezing rate below the surface makes resolution of these processes much less certain. The quality of information which may be obtained from quench-cooled samples is limited by radiation damage. Low-dose microscopy of vitrified thin-film suspensions of macromolecules continues to provide valid structural information at the molecular level. The increased doses needed for X-ray microanalysis present serious problems with the high spatial resolution analysis of thin frozen-hydrated sections although much less damage is observed in dried samples. A case is presented for using the outer fracture faces of frozen-hydrated bulk samples for low-resolution analysis of cells and tissues.

LA Fre For
AB The different types of biological effects produced by ionizing radiations are reviewed. Among the early effects following an acute exposure, the bone marrow syndrome and the intestinal syndrome are briefly described. They are unlikely to appear in the current conditions encountered in dental radiology. As far as skin exposure is concerned (e.g. fingers, hands), acute reactions (moist desquamation, ulceration, etc.) require high doses which are encountered only in accidental conditions. However, chronic dermatitis after repeated low dose exposure is one of the major risks in dental radiology (even without previous acute lesions), if the recommendations of radioprotection are not followed. The danger is ultimately the transformation into a radio-induced skin cancer. Among the late effects, after chronic exposure at low doses, cancer induction and the genetic effects are the most important. The risk coefficient for cancer induction is expressed by the number of lethal cancers induced per unit dose. In his last report (1988), the UNSCEAR assessed the risk coefficient between 4.5 and 7% for an absorbed dose of 1 Gy (low-LET radiation, high dose delivered at high dose rate). A low doses and low dose rates (X-and gamma rays), the UNSCEAR recommends to reduce the above risk coefficients by a factor between 2 and 10. The risk coefficient at low doses is difficult to evaluate since the rate of radio-induced cancers is small compared to the spontaneous cancer incidence. The risk of a severe genetic effect is about 1/3-1/4 of the risk of lethality from radio-induced cancer. Finally, the characteristics of the stochastic and non-stochastic effects are described. The acute effects, the late radiodermatitis and the cataract are examples of non-stochastic effects, while cancer

induction and the genetic effect are stochastic effects. In the Appendix, the most important quantities and units, used in radiation protection, are presented.

AB In recent years, guidelines for radiation protection have increasingly been based on estimates of the risks associated with radiation exposures and judgments regarding acceptable levels of risk. This leads to a more objective basis for regulations if the risk estimates are accurate. However, as enthusiasm for this approach expands, the large uncertainties in the risk estimates are often overlooked, and unreasonable, restrictive applications are possible. Several recent

examples of radiation protection guidelines illustrate the risk-based emphasis underlying today's radiation safety philosophy.

AB Recent progress in molecular biology, genetics and microdosimetry has considerably increased our knowledge of the mechanisms of radiation-induced carcinogenesis. However, as a result of the complexities involved in the many genetic and epigenetic changes in cells leading to the expression of malignancy only years or even decades after radiation exposure, risk coefficients for the quantification of health detriment still have to be derived largely from epidemiological data and animal studies. On the other hand, improved understanding of molecular and cellular mechanisms is increasingly important in testing and refuting hypotheses about the relative carcinogenic potential of different radiation qualities and dose rates, and of low-level exposures.

AB Most of the information currently available on radiation effects comes from the observation of individuals who received high doses, either from one acute exposure or a series of exposures. Because of the uncertainties in extrapolating risks from these studies to the exposure circumstances of most cancers today (in particular, low-level environmental exposure), direct epidemiologic studies of populations receiving low doses chronically are needed. The effects which we want to quantify are likely to be small, however, and extreme care must therefore be put into the design of such studies if they are to be informative for risk assessment purposes. The areas of particular importance in designing risk assessment studies are reviewed. The advantages and limitations of various epidemiological study designs, and the problems and importance of dosimetry are discussed. Examples from the recent epidemiological literature are presented to illustrate the discussion.

AB Total body irradiation (TBI) is used in conditioning regimens prior to bone marrow transplantation (BMT) in haematologic diseases to achieve the objective of eradicating bone marrow stem cells. The dose deliverable to the whole body is limited by the radiation tolerance of the normal tissues, especially of the lung, which is the major dose limiting organ because of the high incidence of interstitial pneumonia. The dose rate is important to successfully affect the therapeutic ratio of TBI and BMT; two different dose-rate schedules have been compared to define radiation damages in all tissues. Twenty mini-pigs were lethally irradiated, TBI was performed with 750 cGy total dose, but with two different midplane dose rates: a low dose rate (LDR) of 5 cGy/min and a quite high dose rate (HDR) of 25 cGy/min. In mini-pigs lethally irradiated with HDR, microscopic examination showed severe hemorrhagic changes in bone marrow, lymphonodes, lung parenchyma and other tissues, more prominent than in LDR mini-pigs. Hystologic pictures showed moderate changes in kidney and liver parenchyma, in thyroid and brain tissue both in HDR and in LDR group. Tissue radiation damages are related not only to TBI total dose, but to the dose-rate; the selection of a low dose-rate is useful to reduce radiation cell killing by accumulation of lethal injury to normal tissues, especially to the lung.

 AB Traditionally, studies of the biological effects of ionizing radiation
 have rested on the triumvirate: (gas-phase) radiation physics,
 biophysical modeling, and radiation biology. Two technical
 developments, the advent of supercomputing as a routine tool in quantum
 solid-state material science and molecular dynamics on the one hand, and
 molecular biology on the other hand, have created--perhaps for the first
 time--the possibility of directly linking a more realistic description of
 the radiation field to observable events at biomolecular level. It also
 becomes increasingly clear that the identification of specific molecular
 targets imposes a challenge to the radiation physics community to be
 equally specific in treating the energy--deposition stage of radiation

action. In this paper: a) I review--and exemplify with results from our own work--the current status in Monte Carlo simulation of gas-phase material (particle transport and stochastic chemistry); b) examine the link between these essentially geometric representations of the track and the concept of "spatial distribution of energy deposition," a staple in radiation modeling; c) advocate an effort towards developing conceptually and calculationally, the field of solid-state microdosimetry; and d) describe methods based on semi-empirical Hamiltonians or quasi-particle techniques for obtaining the frequency-dependent and wave-vector-dependent dielectric response function for biomolecular crystalline systems, which are the main ingredients for describing charged-particle transport.

 TI Radial distribution of dose.
 SO Basic Life Sci 1991;58:163-79; discussion 179-80
 JT BASIC LIFE SCIENCES
 AD University of Nebraska, Lincoln.
 LA Eng
 AB The radial distribution of dose about the path of a heavy ion, principally from delta rays, is one of the central contributions of atomic physics to the systematization of high LET radiation effects in condensed matter, whether the detection arises in chemical, physical, or biological systems. In addition to the radial distribution of dose, we require knowledge of the response of the system to X-rays or gamma-rays or to beams of energetic electrons such that the electron slowing-down spectra from these radiations can approximate the slowing-down spectra from delta rays even at different radial distances from the ion's path. A combination of these data enables us to calculate the action cross sections ion bombardments in all detectors for which this information is available. These cross sections are indispensable for the evaluation of effects caused by high LET radiations. In this paper we focus attention principally on the calculation and measurement of the radial distribution of dose and on their limitations.

TI Phenomenological models.
SO Basic Life Sci 1991;58:339-61; discussion 361-5
JT BASIC LIFE SCIENCES
AD Pacific Northwest Laboratory, Richland, Washington.
LA Eng
AB The biological effects of ionizing radiation exposure are the result of a complex sequence of physical, chemical, biochemical, and physiological interactions which are modified by characteristics of the radiation, the timing of its administration, the chemical and physical environment, and the nature of the biological system. However, it is generally agreed that the health effects in animals originate from changes in individual cells, or possibly small groups of cells, and that these cellular changes are initiated by ionizations and excitations produced by the passage of charged particles through the cells. One way to begin a search for an understanding of health effects of radiation is through the development of phenomenological models of the response. Many models have been presented and tested in the slowly evolving process of characterizing cellular response. Different phenomena (LET dependence, dose rate effect, oxygen effect etc.) and different end points (cell survival, aberration formation, transformation, etc.) have been observed, and no single model has been developed to cover all of them. Instead, a range of models covering different end points and phenomena have developed in parallel. Many of these models employ similar assumptions about some underlying processes while differing about the nature of others. An attempt is made to organize many of the models into groups with similar features and to compare the consequences of those features with the actual experimental observations. It is assumed that by showing that some assumptions are inconsistent with experimental observations, the job of devising and testing mechanistic models can be simplified.

AB Several models and theories are reviewed that incorporate the idea of radiation-induced lesions (repairable and/or irreparable) that can be related to molecular lesions in the DNA molecule. Usually the DNA double-strand or chromatin break is suggested as the critical lesion. In the models, the shoulder on the low-LET survival curve is hypothesized as being due to one (or more) of the following three mechanisms: (i) "interaction" of lesions produced by statistically independent particle tracks, (ii) nonlinear (i.e., linear-quadratic) increase in the yield of initial lesions, and (iii) saturation of repair processes at high dose. Comparisons are made between the various approaches. Several significant advances in model development are discussed; in particular, a description of the matrix formulation of the Markov versions of the repair-misrepair (RMR) and lethal-potentially-lethal (LPL) models is given. The more advanced theories have incorporated statistical fluctuations in various aspects of the energy-loss and lesion-formation process. An important direction is the inclusion of physical and chemical processes into the formulations by incorporating relevant track structure theory (Monte Carlo track simulations) and chemical reactions of radiation-induced radicals. At the biological end, identification of repair genes and how they operate, as well as a better understanding of how DNA misjoinings lead to lethal chromosome aberrations, are needed for appropriate inclusion into the theories. More effort is necessary to model the complex end point of radiation-induced carcinogenesis.

TI Laser/tissue interaction.
 SO Alpha Omegan 1991;84(4):33-6
 JT ALPHA OMEGAN
 AD University of Pittsburgh, School of Dental Medicine.
 LA Eng
 AB When laser light impinges on tissue, it can reflect, scatter, be absorbed, or transmit to the surrounding tissue. Absorption controls to a great degree the extent to which reflection, scattering and transmission occur, and wavelength is the primary determinant of absorption. The CO₂ laser is consistently absorbed by most materials and tissues and the Nd-YAG laser wavelength is preferentially absorbed in pigmented tissues. The factors which determine the initial tissue effect include the laser wavelength, laser power, laser waveform, tissue optical properties, and tissue thermal properties. There are almost an infinite number of combinations of these factors possible, many of which would result in unacceptable damage to the tissues. This underscores the need to thoroughly test any particular combination of these factors on the conceptual, in-vitro, and in-vivo level before a treatment is offered.

 TI Chromosome aberration, cancer mortality and hormetic phenomena among inhabitants in areas of high background radiation in China.
 SO J Radiat Res (Tokyo) 1991 Dec;32 Suppl 2:46-53
 JT JOURNAL OF RADIATION RESEARCH
 AD High Background Radiation Research Group, Beijing, China.
 LA Eng
 AB The respective average annual doses are about 330 and 110 mR/yr, in the high background radiation areas (HBRA) in Yangjiang County and the control areas (CA) in Enping and Taishan Counties. Both the HBRA and CA are in Guangdong Province which borders the South China Sea. The frequencies of chromosome aberration in circulating lymphocytes were examined for persons residing in the HBRA and CA. Those in the HBRA had increased frequencies of detectable abnormalities in stable aberrations (translocations and inversions) and unstable aberrations (dicentric and rings). Previous reports have shown that when samples of circulating lymphocytes taken from inhabitants were tested in vitro for mitotic responses to phytohemagglutinin (PHA) and for the degree of unscheduled DNA synthesis (UDS) induced by UV-irradiation, there were higher responsiveness and UDS rates for those in the HBRA than in the CA. In contrast, mortality from all cancers and those from leukemia, breast and lung cancers that are inducible by radiation was not higher in the HBRA.

Although the differences in the cancer mortality rates for the HBRA and CA are not significant, the findings are compatible with the assumption that the lower mortality from cancer in the HBRA is the result of the hormetic effects of the three-fold higher dose rate of background radiation in that areas. This assumption requires further study.

AB For the first time, a complete computer simulation of physical and chemical reactions at the molecular level has been used to calculate the yield of a chemical species resulting from irradiation of a biological molecule in aqueous solution. Specifically, when a solution of glycylglycine is irradiated anaerobically, an ammonia molecule is released by the action of a hydrated electron, which is produced by irradiation of water. In the computations, Monte Carlo techniques are used to simulate the statistical progression of molecular events as they are assumed to occur. These include the initial physical ionization and excitation of water molecules along a particle track in the liquid; the

subsequent formation of free radicals and other species: and the random diffusion and chemical reactions of the species with each other, the solvent, and solute molecules. We have calculated and measured the yield of ammonia from irradiation of glycylglycine with 250 kVp x-rays as a function of glycylglycine concentration between 0.01 and 1.2 M. Excellent agreement is obtained between predicted and measured results. The literal simulation of events, combined with specific experimental measurements, offers a powerful new tool for studying mechanisms of radiation action and damage at the molecular level.

LA Eng
AB Ultrasoft X-rays are useful for mechanistic studies of ionizing radiation damage in living cells due to the localized nature of their energy depositions. To date radiobiology experiments in this energy region have relied on characteristic X-rays (mainly Alk and Ck) from X-ray tubes. However, limitations in the photon intensity and the available energies from X-ray tube sources prevent a definitive characterization of the relationship between photon energy and biological damage. Synchrotron radiation has the potential to avoid these limitations, since it produces X-rays with high intensity over a continuous spectrum. We have established a synchrotron-based system for radiation biology studies using the ES-0 exposure station of the Center for X-ray Lithography at the University of Wisconsin Synchrotron Radiation Center storage ring, Aladdin. A characterization of the system including spectral and intensity properties of the photon beam is presented. The first mammalian cell survival curve for synchrotron-produced ultrasoft X-rays was generated and is presented.

Cell survival curves of C3H/10T 1/2 cells using synchrotron radiation of 1.48 keV agree with previous data using Alk X-rays (1.49 keV). An RBE of 1.47 +/- 0.30 at the 10% survival level was measured with reference to 250 kVp X-rays.

TI Energy deposition in small cylindrical targets by monoenergetic electrons.
SO Int J Radiat Biol 1991 Nov;60(5):739-56
JT INTERNATIONAL JOURNAL OF RADIATION BIOLOGY
AD Medical Research Council Radiobiology Unit, Didcot, Oxon, UK.
LA Eng
AB Calculations of energy deposition in cylindrical target volumes of diameter and height 1-100 nm, including those similar to the dimensions of biological molecules and structures such as DNA, nucleosomes and chromatin fibre, have been made. The calculations used the Monte Carlo track structure program MOCA8B for electrons of initial energy 0.1-100 keV. Details of the calculation are presented, as well as a selection of results. The frequency distributions of energy deposition events per gray per target, placed at random in a homogeneous aqueous medium, are given for uniform irradiation with monoenergetic electrons of various energies. The frequency distributions have been used to predict the initial biophysical parameters such as relative effectiveness for initial damage. These suggest that the final biological effects which depend on complex local damage may show substantial variations in biological effectiveness for different low linear energy transfer radiations, whereas those that depend on simple local damage may not.

TI Radiation hormesis.
SO J Nucl Med 1991 Feb;32(2):350-9
JT JOURNAL OF NUCLEAR MEDICINE
AD Dept. of Radiation Therapy, Harvard Medical School, Boston, MA 02115.
LA Eng
AB "Radiation hormesis" is the name given to the putative stimulatory effects of low level ionizing radiation (generally in the range of 1-50 cGy of low-LET radiation). Based on historical and pharmacologic principles reminiscent of some of the major tenets of homeopathy, most of these effects are now generally ascribed to protective feedback systems that, upon exposure to low concentrations of toxins, proceed to stimulate metabolic detoxification and repair networks. The activation of these networks may then result in net beneficial effects on the cell, organism or species. Discussions of possible stimulatory effects of low levels of ionizing radiation have recently become entangled with the separate but related question of whether a threshold dose level exists on the radiotoxicologic dose-response curve. This review summarizes some of the relevant historical and scientific data bearing on the question of radiation hormesis. We find the data in support of most of the hormesis postulates intriguing but inconclusive.

 TI [Calculation of the radiation-induced delay in cell division during a study of the induction of chromosome aberrations (the theoretical and experimental bases of the approach)]
 SO Radiobiologiia 1991 Jan-Feb;31(1):59-64
 JT RADIOBIOLOGIIA
 LA Rus For
 AB The possible influence of a radiation-induced delay of cell division on the yield of chromosome aberrations has been analyzed theoretically. The analysis is based on the assumption that the delay is caused by the damages that are realized in the mitosis as chromosome aberrations. It has been shown that the distributions of cells, that are registered by the number of chromosome aberrations, are a function of time of cell fixation and may substantially differ from actual disturbance. There is a correlation between the registered and actual disturbances which is determined by the kinetics of the first mitosis of nonirradiated cells and the degree of the radiation-induced division delay. Some qualitative sequels of the proposed model are in agreement with the experimental data.

LA Eng
AB There are several limitations to the low-temperature techniques which are currently being used for the preparation, examination and analysis of biological and organic samples by means of high-energy beam instrumentation. The low thermal conductivity of samples and the inadequacy of rapid cooling techniques means that, with the exception of thin-film suspensions and the surface of impact-cooled bulk specimens which may be vitrified, ice crystals of varying sizes will be present in nearly all samples which are quench cooled. Data are presented which indicate the depth to which adequate cryo-fixation may be achieved for both morphological and analytical studies. Although dynamic processes may be time resolved in the outer parts of quench-cooled samples, the decreased freezing rate below the surface makes resolution of these processes much less certain. The quality of information which may be obtained from quench-cooled samples is limited by radiation damage. Low-dose microscopy of vitrified thin-film suspensions of macromolecules continues to provide valid structural information at the molecular level. The increased doses needed for X-ray microanalysis present serious problems with the high spatial resolution analysis of thin frozen-hydrated sections although much less damage is observed in dried samples. A case is presented for using the outer fracture faces of frozen-hydrated bulk samples for low-resolution analysis of cells and tissues.

JT INTERNATIONAL JOURNAL OF RADIATION BIOLOGY
AD Department of Medical Physics, University of Wisconsin-Madison 53706.
LA Eng
AB Ultrasoft X-rays are useful for mechanistic studies of ionizing radiation damage in living cells due to the localized nature of their energy depositions. To date radiobiology experiments in this energy region have relied on characteristic X-rays (mainly Alk and Ck) from X-ray tubes. However, limitations in the photon intensity and the available energies from X-ray tube sources prevent a definitive characterization of the relationship between photon energy and biological damage. Synchrotron radiation has the potential to avoid these limitations, since it produces X-rays with high intensity over a continuous spectrum. We have established a synchrotron-based system for radiation biology studies using the ES-0 exposure station of the Center for X-ray Lithography at the University of Wisconsin Synchrotron Radiation Center storage ring, Aladdin. A characterization of the system including spectral and intensity properties of the photon beam is presented. The first mammalian cell survival curve for synchrotron-produced ultrasoft X-rays was generated and is presented. Cell survival curves of C3H/10T 1/2 cells using synchrotron radiation of 1.48 keV agree with previous data using Alk X-rays (1.49 keV). An RBE of 1.47 +/- 0.30 at the 10% survival level was measured with reference to 250 kVp X-rays.

LA Fre For
AB The different types of biological effects produced by ionizing radiations are reviewed. Among the early effects following an acute exposure, the bone marrow syndrome and the intestinal syndrome are briefly described. They are unlikely to appear in the current conditions encountered in dental radiology. As far as skin exposure is concerned (e.g. fingers, hands), acute reactions (moist desquamation, ulceration, etc.) require high doses which are encountered only in accidental conditions. However, chronic dermatitis after repeated low dose exposure is one of the major risks in dental radiology (even without previous acute lesions), if the recommendations of radioprotection are not followed. The danger is ultimately the transformation into a radio-induced skin cancer. Among the late effects, after chronic exposure at low doses, cancer induction and the genetic effects are the most important. The risk coefficient for cancer induction is expressed by the number of lethal cancers induced per unit dose. In his last report (1988), the UNSCEAR assessed the risk coefficient between 4.5 and 7% for an absorbed dose of 1 Gy (low-LET radiation, high dose delivered at high dose rate). A low doses and low dose rates (X-and gamma rays), the UNSCEAR recommends to reduce the above risk coefficients by a factor between 2 and 10. The risk coefficient at low doses is difficult to evaluate since the rate of radio-induced cancers is small compared to the spontaneous cancer incidence. The risk of a severe genetic effect is about 1/3-1/4 of the risk of lethality from radio-induced cancer. Finally, the characteristics of the stochastic and non-stochastic effects are described. The acute effects, the late radiodermatitis and the cataract are examples of non-stochastic effects, while cancer induction and the genetic effect are stochastic effects. In the

Appendix, the most important quantities and units, used in radiation protection, are presented.

 SO Int J Radiat Biol 1991 Nov;60(5):739-56
 JT INTERNATIONAL JOURNAL OF RADIATION BIOLOGY
 AD Medical Research Council Radiobiology Unit, Didcot, Oxon, UK.
 LA Eng
 AB Calculations of energy deposition in cylindrical target volumes of diameter and height 1-100 nm, including those similar to the dimensions of biological molecules and structures such as DNA, nucleosomes and chromatin fibre, have been made. The calculations used the Monte Carlo track structure program MOCA8B for electrons of initial energy 0.1-100 keV. Details of the calculation are presented, as well as a selection of results. The frequency distributions of energy deposition events per gray per target, placed at random in a homogeneous aqueous medium, are given for uniform irradiation with monoenergetic electrons of various energies. The frequency distributions have been used to predict the initial biophysical parameters such as relative effectiveness for initial damage. These suggest that the final biological effects which depend on complex local damage may show substantial variations in biological effectiveness for different low linear energy transfer radiations, whereas those that depend on simple local damage may not.

 LA Eng
 AB In recent years, guidelines for radiation protection have increasingly been based on estimates of the risks associated with radiation exposures and judgments regarding acceptable levels of risk. This leads to a more objective basis for regulations if the risk estimates are accurate. However, as enthusiasm for this approach expands, the large uncertainties in the risk estimates are often overlooked, and unreasonable, restrictive applications are possible. Several recent examples of radiation protection guidelines illustrate the risk-based emphasis underlying today's radiation safety philosophy.

AB Recent progress in molecular biology, genetics and microdosimetry has considerably increased our knowledge of the mechanisms of radiation-induced carcinogenesis. However, as a result of the complexities involved in the many genetic and epigenetic changes in cells leading to the expression of malignancy only years or even decades after radiation exposure, risk coefficients for the quantification of health detriment still have to be derived largely from epidemiological data and animal studies. On the other hand, improved understanding of molecular and cellular mechanisms is increasingly important in testing and refuting hypotheses about the relative carcinogenic potential of different radiation qualities and dose rates, and of low-level exposures.

 AB Most of the information currently available on radiation effects comes from the observation of individuals who received high doses, either from one acute exposure or a series of exposures. Because of the uncertainties in extrapolating risks from these studies to the exposure circumstances of most cancers today (in particular, low-level environmental exposure), direct epidemiologic studies of populations receiving low doses chronically are needed. The effects which we want to quantify are likely to be small, however, and extreme care must therefore be put into the design of such studies if they are to be informative for risk assessment purposes. The areas of particular importance in designing risk assessment studies are reviewed. The advantages and limitations of various epidemiological study designs, and the problems and importance of dosimetry are discussed. Examples from the recent epidemiological literature are presented to illustrate the discussion.

 LA Ita For
 AB Total body irradiation (TBI) is used in conditioning regimens prior to
 bone marrow transplantation (BMT) in haematologic diseases to achieve
 the objective of eradicating bone marrow stem cells. The dose
 deliverable to the whole body is limited by the radiation tolerance of
 the normal tissues, especially of the lung, which is the major dose
 limiting organ because of the high incidence of interstitial pneumonia.
 The dose rate is important to successfully affect the therapeutic ratio
 of TBI and BMT; two different dose-rate schedules have been compared to
 define radiation damages in all tissues. Twenty mini-pigs were lethally
 irradiated, TBI was performed with 750 cGy total dose, but with two
 different midplane dose rates: a low dose rate (LDR) of 5 cGy/min and a
 quite high dose rate (HDR) of 25 cGy/min. In mini-pigs lethally
 irradiated with HDR, microscopic examination showed severe hemorrhagic
 changes in bone marrow, lymphonodes, lung parenchyma and other tissues,
 more prominent than in LDR mini-pigs. Hystologic pictures showed
 moderate changes in kidney and liver parenchyma, in thyroid and brain
 tissue both in HDR and in LDR group. Tissue radiation damages are
 related not only to TBI total dose, but to the dose-rate; the selection
 of a low dose-rate is useful to reduce radiation cell killing by
 accumulation of lethal injury to normal tissues, especially to the lung.

Columbia University, New York.
LA Eng
AB Traditionally, studies of the biological effects of ionizing radiation
have rested on the triumvirate: (gas-phase) radiation physics,
biophysical modeling, and radiation biology. Two technical
developments, the advent of supercomputing as a routine tool in quantum
solid-state material science and molecular dynamics on the one hand, and
molecular biology on the other hand, have created--perhaps for the first
time--the possibility of directly linking a more realistic description of
the radiation field to observable events at biomolecular level. It also
becomes increasingly clear that the identification of specific molecular
targets imposes a challenge to the radiation physics community to be
equally specific in treating the energy--deposition stage of radiation
action. In this paper: a) I review--and exemplify with results from our
own work--the current status in Monte Carlo simulation of gas-phase
material (particle transport and stochastic chemistry); b) examine the
link between these essentially geometric representations of the track
and the concept of "spatial distribution of energy deposition," a staple
in radiation modeling; c) advocate an effort towards developing
conceptually and calculationally, the field of solid-state
microdosimetry; and d) describe methods based on semi-empirical
Hamiltonians or quasi-particle techniques for obtaining the
frequency-dependent and wave-vector-dependent dielectric response
function for biomolecular crystalline systems, which are the main
ingredients for describing charged-particle transport.

TI Radial distribution of dose.
SO Basic Life Sci 1991;58:163-79; discussion 179-80
JT BASIC LIFE SCIENCES
AD University of Nebraska, Lincoln.
LA Eng
AB The radial distribution of dose about the path of a heavy ion, principally from delta rays, is one of the central contributions of atomic physics to the systematization of high LET radiation effects in condensed matter, whether the detection arises in chemical, physical, or biological systems. In addition to the radial distribution of dose, we require knowledge of the response of the system to X-rays or gamma-rays or to beams of energetic electrons such that the electron slowing-down spectra from these radiations can approximate the slowing-down spectra from delta rays even at different radial distances from the ion's path. A combination of these data enables us to calculate the action cross sections ion bombardments in all detectors for which this information is available. These cross sections are indispensable for the evaluation of effects caused by high LET radiations. In this paper we focus attention principally on the calculation and measurement of the radial distribution of dose and on their limitations.

JT BASIC LIFE SCIENCES
AD Pacific Northwest Laboratory, Richland, Washington.
LA Eng

AB The biological effects of ionizing radiation exposure are the result of a complex sequence of physical, chemical, biochemical, and physiological interactions which are modified by characteristics of the radiation, the timing of its administration, the chemical and physical environment, and the nature of the biological system. However, it is generally agreed that the health effects in animals originate from changes in individual cells, or possibly small groups of cells, and that these cellular changes are initiated by ionizations and excitations produced by the passage of charged particles through the cells. One way to begin a search for an understanding of health effects of radiation is through the development of phenomenological models of the response. Many models have been presented and tested in the slowly evolving process of characterizing cellular response. Different phenomena (LET dependence, dose rate effect, oxygen effect etc.) and different end points (cell survival, aberration formation, transformation, etc.) have been observed, and no single model has been developed to cover all of them. Instead, a range of models covering different end points and phenomena have developed in parallel. Many of these models employ similar assumptions about some underlying processes while differing about the nature of others. An attempt is made to organize many of the models into groups with similar features and to compare the consequences of those features with the actual experimental observations. It is assumed that by showing that some assumptions are inconsistent with experimental observations, the job of devising and testing mechanistic models can be simplified.

AB Several models and theories are reviewed that incorporate the idea of radiation-induced lesions (repairable and/or irreparable) that can be related to molecular lesions in the DNA molecule. Usually the DNA double-strand or chromatin break is suggested as the critical lesion.

In the models, the shoulder on the low-LET survival curve is hypothesized as being due to one (or more) of the following three mechanisms: (i) "interaction" of lesions produced by statistically independent particle tracks, (ii) nonlinear (i.e., linear-quadratic) increase in the yield of initial lesions, and (iii) saturation of repair processes at high dose. Comparisons are made between the various approaches. Several significant advances in model development are discussed; in particular, a description of the matrix formulation of the Markov versions of the repair-misrepair (RMR) and lethal-potentially-lethal (LPL) models is given. The more advanced theories have incorporated statistical fluctuations in various aspects of the energy-loss and lesion-formation process. An important direction is the inclusion of physical and chemical processes into the formulations by incorporating relevant track structure theory (Monte Carlo track simulations) and chemical reactions of radiation-induced radicals. At the biological end, identification of repair genes and how they operate, as well as a better understanding of how DNA misjoinings lead to lethal chromosome aberrations, are needed for appropriate inclusion into the theories. More effort is necessary to model the complex end point of radiation-induced carcinogenesis.

JT ALPHA OMEGAN
AD University of Pittsburgh, School of Dental Medicine.
LA Eng
AB When laser light impinges on tissue, it can reflect, scatter, be absorbed, or transmit to the surrounding tissue. Absorption controls to a great degree the extent to which reflection, scattering and transmission occur, and wavelength is the primary determinant of absorption. The CO2 laser is consistently absorbed by most materials and tissues and the Nd-YAG laser wavelength is preferentially absorbed in pigmented tissues. The factors which determine the initial tissue effect include the laser wavelength, laser power, laser waveform, tissue optical properties, and tissue thermal properties. There are almost an infinite number of combinations of these factors possible, many of which

would result in unacceptable damage to the tissues. This underscores the need to thoroughly test any particular combination of these factors on the conceptual, in-vitro, and in-vivo level before a treatment is offered.

TI Chromosome aberration, cancer mortality and hormetic phenomena among inhabitants in areas of high background radiation in China.
SO J Radiat Res (Tokyo) 1991 Dec;32 Suppl 2:46-53
JT JOURNAL OF RADIATION RESEARCH
AD High Background Radiation Research Group, Beijing, China.
LA Eng
AB The respective average annual doses are about 330 and 110 mR/yr, in the high background radiation areas (HBRA) in Yangjiang County and the control areas (CA) in Enping and Taishan Counties. Both the HBRA and CA are in Guangdong Province which borders the South China Sea. The frequencies of chromosome aberration in circulating lymphocytes were examined for persons residing in the HBRA and CA. Those in the HBRA had increased frequencies of detectable abnormalities in stable aberrations (translocations and inversions) and unstable aberrations (dicentric and rings). Previous reports have shown that when samples of circulating lymphocytes taken from inhabitants were tested in vitro for mitotic responses to phytohemagglutinin (PHA) and for the degree of unscheduled DNA synthesis (UDS) induced by UV-irradiation, there were higher responsiveness and UDS rates for those in the HBRA than in the CA. In contrast, mortality from all cancers and those from leukemia, breast and lung cancers that are inducible by radiation was not higher in the HBRA. Although the differences in the cancer mortality rates for the HBRA and CA are not significant, the findings are compatible with the assumption that the lower mortality from cancer in the HBRA is the result of the hormetic effects of the three-fold higher dose rate of background radiation in that areas. This assumption requires further study.

AB For the first time, a complete computer simulation of physical and chemical reactions at the molecular level has been used to calculate the yield of a chemical species resulting from irradiation of a biological molecule in aqueous solution. Specifically, when a solution of glycylglycine is irradiated anaerobically, an ammonia molecule is released by the action of a hydrated electron, which is produced by irradiation of water. In the computations, Monte Carlo techniques are used to simulate the statistical progression of molecular events as they are assumed to occur. These include the initial physical ionization and excitation of water molecules along a particle track in the liquid; the subsequent formation of free radicals and other species; and the random diffusion and chemical reactions of the species with each other, the solvent, and solute molecules. We have calculated and measured the yield of ammonia from irradiation of glycylglycine with 250 kVp x-rays as a function of glycylglycine concentration between 0.01 and 1.2 M. Excellent agreement is obtained between predicted and measured results. The literal simulation of events, combined with specific experimental measurements, offers a powerful new tool for studying mechanisms of radiation action and damage at the molecular level.

AB The oxidation yields (G) for 8.86 and 13.55 keV X-rays produced by synchrotron radiation were measured using an iron(II) sulphate (Fricke) solution. Monoenergetic X-rays were produced using a silicon crystal monochromator. The X-rays were absorbed in 0.4 M sulphuric acid-iron(II) sulphate solution and FeIII ion yields were measured and corrected for escape fractions resulting from scattering using Monte Carlo calculations. Doses in the solution were determined using a thin window, parallel plate chamber calibrated against a primary standard free-air chamber at the Electrotechnical Laboratory (Osaka, Japan). Yields (G) of 1.50 ± 0.06 and 1.43 ± 0.06 $\mu\text{mol J}^{-1}$ were obtained for 8.86 and 13.55 keV X-rays respectively.

AB The public's preceptions about the risks of radiation are adversely influenced by the many negative reports by the media on the hazards of all radiation. As a result, patients express concern about the risks of radiation from radiologic examinations. Radiologists are well positioned to dispel these fears because of their training and their access to and ability to interpret information from scientific organizations specifically concerned with the determination of radiation risk. To do this, radiologists must be willing to communicate with patients and be accessible. Pamphlets and handouts can be given to anxious patients before examinations. In direct interaction with patients, the radiologist must listen to them and be prepared to address their concerns, especially those about repeat examinations, exposure during pregnancy, inadvertent exposure of the fetus, exposure of children, use of radiation in research, and misadministration of radionuclides. In addition, radiologists can help patients by educating referring physicians, other medical staff, and nurses. They can also reach the public by being a spokesperson at meetings of local organizations or by accepting opportunities to speak to the media. All these efforts help counteract negative perceptions aroused by the media.

TI Effect of preirradiation of transplantation site on growth characteristics and hypoxic fractions in human colon tumor xenografts.

SO Cancer Res 1992 Apr 15;52(8):2162-6

JT CANCER RESEARCH

AD Department of Radiation Medicine, Brown University School of Medicine, Providence, Rhode Island 02912.

LA Eng

AB The volumetric growth curves and hypoxic fractions of seven different human colon tumor lines (clone A, clone D, WiDR, SW480, SW620, DLD-2, and HCT-8) xenografted into the flank regions of either unirradiated nude mice or mice that had received 17.5 Gy of 250-kVp X-rays 1 day prior to implantation were biologically analyzed using the Verhulstian equation. Significant variation was found among tumors with respect to both initial growth rates (r , days⁻¹) and theoretical final volumes (carrying capacities, K , mm³). In radiation-damaged normal tissue, tumors grew relatively well for about the first 2 wk postimplantation, attaining volumes of about 70 to 155 mm³. Then, tumor growth rates altered. This effect varied from relatively minor effects on growth rate (tumors of clones A and D) to inhibition of growth, with actual decreases in tumor volume (e.g., WiDr, SW480, SW620, HCT-8, and DLD-2). After this short-term transience in growth kinetics, neoplasms began to steadily regrow at about 3 wk postimplantation, albeit at a slower rate than that seen in controls. Tumor bed effect values were calculated using the ratio of times at which control tumors and tumors growing in the radiation-injured tissue reached a volume of 7.5% of the K values derived from the respective control growth curves. Values for clone D, clone A, and WiDR, SW480, SW620, DLD-2, and HCT-8 tumors were, respectively, 1.89, 2.41, 3.48, 3.62, 2.82, 3.66, and 3.65, indicating that tumor bed effect responses varied by almost 100%, even for cancers of the same neoplastic class. Also, the hypoxic fractions of all tumors growing in radiation-damaged sites were increased as compared with levels in controls.

TI Distribution and biological effects of inhaled $^{239}\text{Pu}(\text{NO}_3)_4$ in cynomolgus monkeys.
SO Radiat Res 1992 Apr;130(1):79-87
JT RADIATION RESEARCH
AD Lovelace Inhalation Toxicology Research Institute, Albuquerque, New Mexico 87185.
LA Eng
AB Twenty male cynomolgus monkeys were exposed by inhalation either to an aerosol of $^{239}\text{Pu}(\text{NO}_3)_4$ to produce projected initial lung burdens of either 40, 10, or 4 kBq or to a carrier aerosol as a control. Animals died or were sacrificed at 0.01, 1, 3, 6, 12, 24, 40, and 99 months after inhalation, and the distribution and biological effects of the ^{239}Pu were determined. The ^{239}Pu cleared efficiently from the lungs so that less than 0.05 kBq remained at 99 months after exposure to 40 kBq. Total skeletal ^{239}Pu activity was nearly constant after the first year, but the fraction of the body burden in skeleton at sacrifice increased with time up to 99 months because of clearance from other organs. Plutonium in the liver increased to a peak at 1 year and then decreased to about 10% of the peak value at 99 months. Plutonium in the testes was localized in the interstitial tissue with only 0.01 to 0.002% of the projected lung burden remaining in testes at 99 months after inhalation. Three animals exposed to 40 kBq of ^{239}Pu died of radiation-related pulmonary pneumonitis and fibrosis. A primary papillary adenocarcinoma of the lung was identified in one animal exposed to 40 kBq initial lung burden and sacrificed 99 months after inhalation. The frequency of chromosome aberrations in blood lymphocytes was significantly elevated only in monkeys with projected deposits of 40 kBq of ^{239}Pu . There was no change in aberration frequency in other exposure groups as a function of inhaled activity, time after exposure, or calculated total dose to the lungs. Only in monkeys that had marked radiation-induced pathological changes in the lung did the frequency of chromosome-type aberrations increase significantly, to a value about twice the control level. In cynomolgus monkeys, chromosome aberration frequency in blood lymphocytes is not a good indicator of radiation dose or damage from inhaled soluble plutonium.

TI [The combined action of gamma irradiation and hyperthermia on the structure of the cell population in the Chinese hamster]
SO Radiobiologiia 1992 Jan-Feb;32(1):112-6
JT RADIOBIOLOGIIA
LA Rus For
AB A change in the structure of FAF-28 Chinese hamster cell population occurred during 24 h following gamma-irradiation or hyperthermia heating, or the effect of both factors was studied by flow cytofluorometry. With radiation delivered immediately after heating the distribution of cells among cycle phases was nearly the same as with hyperthermia alone: the share of cells at the S-phase was invariable during the first 4-6 h, then it slowly diminished; at G1 it slowly decreased and at G2 increased. When irradiation preceded heating the pattern of cell redistribution during the first hours was the same as that with radiation alone: the "wave" of transition from G1 to S phase was the same, but shorter in amplitude and longer in time; then cells were accumulated at G2+M and remained there for 24 h. Thus, of the two factors applied, the first was the major one in changing the cell population structure during the first hours after treatment. In 24 h the result was the same, that is, the considerable accumulation of cells at G2+M.

AB The production of acoustic waves following the absorption of energy deposited by ionizing radiation, with a consequent production of localized thermal spikes has been confirmed by a number of papers published in the physics literature. This paper reviews the basic theory and presents most of the supporting experimental data. Some of the experimental methods used and the results obtained are summarized. In addition to the rather straightforward and routine use of acoustic phenomena produced by ionizing radiation for the detection and measurements of such radiation, there are some special applications that appear to be especially attractive for medical physics. Some of these are unique to ionizing radiation in that the amplitude of the ultrasound wave is proportional to the energy deposited in small volumes at localized sites of these interactions, while others derive from methodologies already in use with nonionizing radiations. The detection and measurement of this ultrasonic radiation could possibly lead to methods for the study of such fundamental phenomenon as track structure, precision localization of therapeutic treatment beams, and even the possible imaging of internal anatomic structures to provide on-line portal images.

AB A 34-year-old white man with the human immunodeficiency virus infection had a large Kaposi sarcoma lesion of his foot. This was treated with local radiation therapy consisting of 2700 rads administered in 15 fractions during a period of 28 days. Ten months later, the patient had painful disseminated Kaposi sarcoma and was treated with a 10 mg/m² dose of intravenous vinblastine. Forty-eight hours after receiving the chemotherapy, the patient had an area of localized painful erythema develop, swelling, and vesicular eruption over the previous site of radiation therapy. This was healed by the fifth day after chemotherapy. No additional vinblastine was administered. Radiation recall occurring in a patient with significant immunosuppression (CD4 lymphocytes, 30 cells/microliters) possibly suggests that the tissue response is not a lymphocyte-mediated event.

TI Frequency and nature of specific-locus mutations induced in female mice
by radiations and chemicals: a review.
SO Mutat Res 1992 Dec;296(1-2):107-27
JT MUTATION RESEARCH
AD Biology Division, Oak Ridge National Laboratory, TN 37831-8077.
LA Eng
AB The inducibility of heritable mutations in female mammals has been
measured in the mouse specific-locus test (SLT). For radiation-induced
mutations, a large body of data has been accumulated that includes
information about biological and physical factors that influence
mutation yields. However, relatively few SLT studies in females have
been conducted with chemicals to date. A single estimate of the

spontaneous mutation rate in oocytes, 6/536,207, has been derived as the most appropriate one to subtract from experimental rates. This rate is highly significantly below the spontaneous mutation rate in males. Mutations recovered from females mutagenized at any time after about the 12th day post-conception are induced in non-dividing cells. In adult females, most oocytes are arrested in small follicles; maturation from this stage to ovulation takes several weeks. High-dose-rate radiations are more mutagenic in mature and maturing oocytes than in spermatogonia of the male; on the other hand, no clearly induced mutations have been recovered from irradiated arrested oocytes. Efficient repair processes have been invoked to explain the latter finding as well as the upward-curving dose-effect relation for acute irradiation, and the fact that dose protraction drastically reduces mutation yield from mature and maturing oocytes. The dose-protraction effect is much greater than that found in spermatogonia. Radiation-induced mutation rates in embryonic, fetal, and newborn females are overall lower than those in the mature and maturing oocytes of adults. A dose-protraction effect has also been demonstrated at an early developmental stage when the nuclear morphology of mouse oocytes most resembles that of the human. Of only 5 chemicals so far explored for their effect in oocytes, 2 (ethylnitrosourea, ENU, and triethylenemelamine, TEM), and possibly a third (procarbazine hydrochloride, PRC), are mutagenic--with at least one of these (ENU) mutagenic in arrested as well as maturing oocytes. However, the mutation rate is, in each case, lower than for treated male germ cells. By contrast, ENU-induced mutation yield for the maternal genome of the zygote is an order of magnitude higher than that for the zygote's paternal genome or for spermatogonia. A high proportion of mutants derived from chemical treatment of oocytes (including the oocyte genome in zygotes) are mosaics, probably owing to lesions affecting only 1 strand of the DNA. A characteristic of specific-locus mutations induced in oocytes is that they include a considerably higher percentage of large (multi-locus) lesions (LLs) than do mutations induced in spermatogonia.(ABSTRACT TRUNCATED AT 250 WORDS)

AB A brief review is presented of the background to, and the principles involved in, the development of redox-sensitive drugs for use in cancer therapy. The role of redox processes in the action of various types of radiosensitizers and in the activation of bioreductive drugs is described. The mechanisms by which many simple hypoxic cell radiosensitizers act are believed to involve fast electron transfer processes involving DNA. Some of these agents can also function as hypoxic cell cytotoxins, although the mechanisms involved are different. These "bioreductive drugs" are activated by intracellular metabolic reduction mediated through various cellular reductases. Usually, though not always, bioreduction is favored under hypoxic conditions, and this is why many of these compounds display differential cytotoxicity to hypoxic cells. This is one of the rationales for selectivity in solid tumors. The potencies of both hypoxic cell radiosensitizers and bioreductive drugs are strongly correlated with their electron affinities. Classes of bioreductive agents of current interest are described briefly. These include simple and dual-function nitroheterocycles including the highly potent compound RB-6145, quinone-based drugs including analogues of mitomycin C, and heterocyclic compounds containing N-oxide functions. The study of bioreductive agents for potential use as adjuncts for various approaches to cancer treatment is described.

AB The theory of dual radiation action (A. M. Kellerer and H. H. Rossi, Curr. Top. Radiat. Res. Q. 8, 85-158, 1972) has attributed the effects of ionizing radiation on eukaryotes to the production of molecular changes (sublesions) that combine pairwise to produce injury (lesions) responsible for radiation effects. If the yield of sublesions is independent of radiation quality (as is currently assumed), dual radiation action results in the well-known proportionality between the average yield of lesions and $\alpha + \beta D$, where β is a radiation-independent quantity. It has, however, been observed that β changes with radiation type. In this paper we propose an explanation of this discrepancy. Specifically, we suggest that dual radiation action-type processes where β is variable are the result of a mechanism--termed compound dual radiation action--which consists of a sequence of simple dual radiation action processes, each process being the causative agent for the next one. The sequence, single-strand DNA breaks, double-strand DNA breaks (chromosome breaks), and exchange-type chromosomal aberrations, is one such example examined in the paper.

AB Radiation oncology is a dynamic discipline. The radiobiologic basis for understanding and anticipating treatment effects continues to grow. Improved understanding is permitting study of altered fractionation regimens and safer integration into the clinic of high-dose-rate brachytherapy. A new agent, SR 4233, may completely revise clinical approaches to tumor hypoxia, especially intermittent (or "dynamic") hypoxia. The availability of computer technology that permits three-dimensional treatment planning with unusual beam and treatment table orientations should result in isodose lines that conform very tightly to desired treatment volumes, permitting higher doses of treatment with acceptable normal-tissue risk. The biology of cytotoxic drug and irradiation interactions and of cytokine and irradiation interactions is an area of growing promise. Combined chemotherapy and radiotherapy treatments have, in the past year, suggested major improvements in the management of esophageal and laryngeal cancer. The importance of local and regional tumor control in contributing to clinical disease course is being understood with increasing clarity, validating the development of technically demanding new approaches to administering irradiation and the use of adjunctive radiotherapy following chemotherapy for selected neoplastic diseases.

LA Eng

AB A published collation of data for control of head and neck cancer in over 4500 patients has been subjected to direct analysis to deduce dose-response, fractionation, and time parameters. The analysis confirms the presence of a significant time factor of the order of 0.5-0.6 Gy/day, deduced previously using various assumptions and normalisation procedures. In addition, the dose-response curve was characterised by $D_{0.5} = 29$ Gy which contributed to long "effective" doubling times being deduced for tumour clonogens in the patient

population as a whole. Some late-reacting normal tissues also show significant time factors, and furthermore, their dose-response curves are in general steeper than for tumours. Hence, care should be taken in accelerating treatments to improve local control, if the treatments are truly at tolerance regarding late-appearing major complications.

JT INTERNATIONAL JOURNAL OF RADIATION BIOLOGY
AD Division of Radiation Biology, Faculty of Pharmaceutical Sciences, Nagasaki University, Japan.

LA Eng
AB We have measured expression of transformed phenotypes in human embryo (HE) cells repeatedly irradiated with a dose of 7.5 cGy per week throughout the life span of these cells in vitro. Irradiation was repeated until the cells had accumulated 195 cGy at which time the cells had reached the equivalent of their 26th passage and samples of cells at several passages were assayed for cell survival by colony formation, for mutation at hypoxanthine guanine phosphoribosyl transferase (HGPRT) locus and for transformation by focus formation. The lifespan (mean population doublings) of multiple irradiated cultures with a total dose of 97.5 cGy was slightly, but significantly, prolonged over that of controls. For example, if cells had accumulated 195 cGy, the maximum number of cell division of HE cells in vitro extended to 130-160% of non-irradiated control. Although transformed foci were not observed with cells until cells had accumulated 97.5 cGy, it increased with increasing accumulated dose. No cells, however, showed unlimited life span in vitro and also expressed tumorigenicity.

AB 363 men who have been working under conditions of additional irradiation in terms from few hours to some months were cytogenetically examined to define individual irradiation. In 111 men with the known dose of irradiation (5-140 cGy), the results of cytogenetic evaluation indicated, as a rule, a less intensive irradiation than physical dosimetry. This could be caused by elimination of chromosome aberrations, individual sensitivity, peculiar irradiation situation, or

in some cases by incorrect evaluation of dose. In 252 men with the unknown dose of irradiation a tentative level was determined as based on frequency of metaphases with chromosome type aberrations. According to the study the absorbed dose was below 25 cGy in 209 cases, 26-50 cGy in 39 cases, and reached 51-90 cGy in 4 cases.

TI Mutation induction by ionizing radiation in three human bladder tumour cell lines.
SO Int J Radiat Biol 1993 Jan;63(1):1-5
JT INTERNATIONAL JOURNAL OF RADIATION BIOLOGY
AD Radiotherapy Research Unit, Institute of Cancer Research, Sutton, Surrey, UK.
LA Eng
AB Mutation induction at the hypoxanthine-guanine phosphoribosyl transferase (hprt) locus has been studied in three human bladder tumour cell lines of varying radiosensitivity. U1-S40b, a radiosensitive mutant clone of MGH-U1, has been previously reported to show no difference in split-dose recovery or low dose-rate sparing, but to have

an impaired repair fidelity when compared to its parent line. In this paper we have shown that U1-S40b is less mutable at the hprt locus at a similar level of survival. This may represent an increased incidence of severe or non-repairable lesions, making hprt- mutants poorly recoverable in U1-S40b when compared to MGH-U1. No difference was seen in mutation induction between MGH-U1 and RT112, another human bladder tumour cell line of similar radiosensitivity to MGH-U1.

AB Five types of mass screening programs for cancer are performed under the auspices of the Adult Health Promoting Act of the Japanese Government. The cancers involved are those of stomach, uterus, lung, breast and colon. Radiological images are routinely used for the screening of stomach and lung cancers, and mammography will be employed in the near future. In this study, the risk due to radiation exposure in the above-mentioned screening programs was estimated for an individual who participates in the screening of each cancer annually. The dose absorbed at each screening was estimated and an additive risk model was used as the pattern of occurrence of radiation-induced cancers for simplicity. Safety was also estimated. Results showed that the risk of a shortened life-expectancy as a result of undergoing annual mass screening for breast, stomach and lung cancer was insignificant in comparison with the average life-expectancy of about 80 years for Japanese men and women, and much smaller than the benefit of mass screening expressed in terms of prolonged life-expectancy. However, it should be emphasized that a quality control program must be established to keep the dose absorbed at each X-ray screening examination as low as reasonably possible.

AB A code for calculations of electron, ion and photon radiation action on tissue-equivalent matter (water vapor) by the Monte Carlo technique is presented. The new "fluctuation detector" method is efficient in evaluating of probability distributions and moments of absorbed energy and number of ionizations in small sites. Spatial and energy distributions of particles fluences and fluctuation characteristics of radiation action on spherical and thread-like sites of nanometer diameter are compared with various experimental and theoretical data and discussed. Non-equivalence of energy absorption and ionization events and consequences of that non-equivalence are numerically analysed. As an example of radiobiological application the yield of single- and double-strand breaks of DNA is calculated in a threshold model.

 AB (1) The biologic effects of ionizing radiation at the cellular and molecular levels differ from those of many chemical agents. Radiation is a classic genotoxic agent. The important DNA lesion with respect to its cytotoxic and mutagenic effects appears to be the DNA double strand break, whereas chemotherapeutic alkylating agents induce primarily base damage from adduct formation and cross-linking. Radiation-induced mutations result primarily from large-scale structural changes in DNA as a result of mechanisms such as chromosomal deletions, rearrangements, and homologous recombination, rather than point mutation as generally observed with alkylating agents. Finally, radiation is highly cytotoxic; a significantly increased frequency of specific gene mutations is usually observed only following doses that produce significant cell killing. (2) Radiation may not be a very potent inducer of second malignant tumors, at least in most cases. This prediction is derived from the localized nature of the exposure during clinical radiotherapy, in which the dose to normal tissues is minimized, and from the fact that radiation tends to be cytotoxic rather than mutagenic. The very high doses employed in curative radiotherapy may thus kill potentially transformed cells in the field. An exception to this general prediction may be Hodgkin's disease, in which a relatively large volume of tissue is treated with lower total radiation doses. (3) We have a firm scientific basis on which to predict the carcinogenic effects of radiation at many tissue sites, owing to extensive quantitative epidemiologic data in human populations. Unlike for chemical agents, radiation can be easily detected, and the absorbed dose to critical tissues is precisely measured. Thus, we know about the sensitivity of many target tissues to radiation-induced cancer. (4) A number of factors can modify the carcinogenic effects of radiation. It is likely that important interactive effects will occur between radiation and chemotherapeutic alkylating agents, which may depend upon the timing and order of the treatments as well as the particular agent(s) employed. (5) Genetic predisposition to radiation-induced cancer may be a confounding factor in the prediction of its effects in any given individual.

JT RADIATION RESEARCH
AD Department of Experimental Radiology, Shiga University of Medical Science, Japan.
LA Eng
AB Sequences of 38 independent X-ray-induced mutations in a cDNA of the human hypoxanthine phosphoribosyltransferase (hprt) gene were analyzed after it was integrated into mammalian chromosomes as part of a shuttle vector. There were 15 base substitutions (39%), 9 frameshifts (24%), 11 deletions (29%), and 3 other mutations (8%) of two kinds. Radiation-induced mutations were found throughout the coding region of the gene. Base substitution mutations occurred more often at A:T sites than at G:C sites, and there were more transversions than transitions. Most of the frameshifts and deletions had short direct repeats or a run of several identical bases at the site of the mutation. A slippage misalignment mechanism, suggested previously, can account for the generation of these classes of mutations. The kinds, distribution, and possible mechanism of X-ray-induced mutations were similar to those of spontaneous mutations.

AB Because of the strong scientific evidence in support of radiation hormesis, we can no longer ignore this concept. There is, however, need for additional, carefully documented investigations in selected biological systems exposed to LLIR if the matter of radiation hormesis is to be settled once and for all. This need should be addressed without delay, as the matter of benefits derived from LLIR exposure could have major economic and epidemiologic implications. If radiation hormesis becomes firmly established, the requirements for LLIR protection might be relaxed, leading to a sizable cost saving, and the fear of nuclear energy should abate. If this happens, the evergrowing problems associated with energy production from fossil fuels on the one hand and the continued improvements in nuclear reactor technology on the other, will force a world-wide reassessment of risks and benefits associated with nuclear energy. Furthermore, as discussed herein, the major source of exposure from background radiation comes from the inhalation of radon gas. The very high cost associated with effective radon abatement would lead to an abandonment of this mitigation effort so that the limited funds available to improve public health world wide could be used more effectively elsewhere. Thus, we conclude that the time is now to consider eliminating the concept of the radiation paradigm from scientific thinking. We must not continue to unequivocally accept the propositions that 1) all radiation is harmful and 2) that the health effects of LLIR may be directly inferred by scaling down from known deleterious high-dose effects, in as much as there is no scientific basis for an agent not to cause multiple effects.(ABSTRACT TRUNCATED AT 250 WORDS)

AB A biologically based model is developed for normal tissue complication probability as a function of dose and irradiated volume fraction for organs such as the kidney and the lung. The organ is assumed to be composed of functional subunits (FSUs) which are arranged in a parallel architecture. The complication is produced only if a sufficiently large

fraction of the FSUs are inactivated by radiation and an FSU is inactivated only when all the clonogenic cells within it are killed. The linear-quadratic model is used for the dose-response of individual cells within an FSU. The predictions of this model are compared with those of an empirical power law function for uniform whole and partial organ irradiation.

 LA Eng
 AB In order to describe the life-prolonging effect of some agents that are
 harmful at higher doses, ionizing radiations in particular, a stochastic
 model is developed in terms of accumulation and progression of
 intracellular lesions caused by the environment and by the agent itself.
 The processes of lesion repair, operating at the molecular and cellular
 level, are assumed to be responsible for this hormesis effect within the
 framework of the proposed model. Properties of lifetime distributions,
 derived for analysis of animal experiments with prolonged and acute
 irradiation, are given special attention. The model provides efficient
 means of interpreting experimental findings, as evidenced by its
 application to analysis of some published data on the hormetic effects
 of prolonged irradiation and of procaine on animal longevity.

JT RADIATION RESEARCH
AD Department of Chemical Engineering, University of Rochester, New York
14627-1066.
LA Eng
AB Distributions associated with random tracks in bodies are important to understanding the effects of radiation on objects and their response to it. Results of computer simulations are presented for the distribution densities, average lengths, and relative frequencies of the various types of random tracks resulting from the traversal of random arrays of cylinders by random lines. We consider arrays consisting of freely overlapping long circular cylinders distributed randomly with their axes parallel to a line or a plane, or oriented randomly in the three-dimensional space. The problem of random tracks lying outside the cylinders (external random tracks) is treated analytically, while the distributions of random tracks found within the cylinders (internal random tracks) are determined using a simulation procedure based on a discrete step-by-step random walk mechanism applied in finite samples of the arrays. The numerical results are used to validate various general analytical results for the distribution densities and average lengths of random tracks in structures of arbitrary shape. It is found that the distributions of internal random tracks exhibit strong dependence on the cylinder volume fraction, while the external random tracks are distributed independently of the cylinder volume fraction for all three cases of orientation distribution. At the limit of high cylinder volume fraction, the internal random track distributions approach the distributions of the external random tracks, while at the other extreme, they become, as expected, identical to those determined analytically for a single infinite cylinder.

AB The action of low dose irradiation on the radiosensitivity of HeLa cells was studied. It was shown that preliminary irradiation of cells by dose of 3 cGy induces the adaptive response: decreasing of number of cells with micronuclei after posterior irradiation by doses of 2.0 and 3.0 Gy.

The maximum level of the adaptive response is reached in 4 h and is observed in 3 cell cycles. When the dose of preliminary irradiation increases to 40 cGy the adaptive response is not observed, however the radiosensitivity of cells increases.

JT MAGNETIC RESONANCE IN MEDICINE
AD Department of Physics, Case Western Reserve University, Cleveland, Ohio.
LA Eng
AB We present preliminary results for a 3D finite element calculation to evaluate RF penetration in conducting dielectric materials at high field strengths. A tetrahedral mesh is used along with a Coulomb gauge constraint in a finite element method that yields excellent numerical stability at high frequencies. Accuracy is verified by comparisons with analytic solutions for single-layer and multiple-layer heterogeneous systems and for a 3D spherical model. We have also compared the finite element model with experimental results presented by Foo et al., Magn. Reson. Med. 23, (1992). Agreement is very good and argues for the usefulness of the method in the calculation of RF penetration and RF power deposition effects in heterogeneous objects.

 JT OPTOMETRY AND VISION SCIENCE
 AD Morton D. Sarver Laboratory for Contact Lens and Corneal Research,
 School of Optometry, University of California, Berkeley.
 LA Eng
 AB Ultraviolet (UV) radiation has been proposed as an alternative method
 for contact lens disinfection. In order for UV radiation to be
 considered a viable contact lens disinfection method, its effects on
 lens polymers and parameters must be minimal. To evaluate this, soft
 contact lenses from each of the four FDA categories, soft lenses with
 handling tints, and rigid gas permeable (RGP) lenses were exposed to UV
 radiation in a controlled laboratory setting and their parameters
 measured. After 20 h of UV exposure, we found statistically significant
 changes in at least one parameter for each lens type evaluated. Most of
 these changes were small and within the error of measurement and,
 therefore, were not considered clinically significant. However, the
 group 2 soft lenses showed an increase in all four measured
 parameters--power, center thickness, diameter, and water content. These
 changes may have an impact on lens fitting characteristics and
 performance. Other than these changes for group 2 soft lenses, 20 h of
 UV exposure appeared to have little clinical effect on the contact
 lenses evaluated. This suggests that UV radiation may prove to be a
 feasible alternative method of disinfection for most types of contact
 lenses.

SO Izv Akad Nauk Ser Biol 1993 Nov-Dec;(6):824-32

JT IZVESTIIA AKADEMII NAUK. SERIIA BIOLOGICHESKAIA

LA Rus For

AB The different cellular responses to high (suppressive) and low (stimulant) doses of atomic radiation suggest understanding of radiation hormesis, since the well developed mechanisms of damaging effect of atomic radiation (radiodamage of DNA, chromosomal aberrations, death of radiosensitive cells) cannot explain the converse effects of low stimulant radiation doses. Here the direct or indirect excitation of membrane receptors comes to the foreground. The excitation activates membrane-bound enzymes which control many vitally important processes. Now that an increasing proportion of the general population is exposed to low chronic doses of ionizing radiation, the knowledge of radiation hormesis acquires great importance, particularly, for temporal predictions of its consequences. Although this problem is far from complete understanding, it is, undoubtedly, wrong to estimate the hazard of the low radiation doses by straight extrapolation of the data obtained with much higher doses and during shorter time periods.

JT NEUROLOGIA MEDICO-CHIRURGICA
AD Department of Neurosurgery, Niigata University.
LA Eng
AB The effects of irradiation on cytokine production in glioma cell lines, NP1, NP2 and NP3, were studied. Culture supernatants were collected after 6, 24, 48 or 72 hours and the concentrations of interleukin (IL)-6 and IL-8 measured by enzyme-linked immunosorbent assay. Spontaneous and IL-1 beta-stimulated productions were analyzed. Some cells were given a single dose of Lineac irradiation (10 or 20 Gy). Production of IL-6 (with or without IL-1 beta stimulation) increased gradually to a maximum after 72 hours, more in the 20 Gy-irradiated cells than 10 Gy cells ($p < 0.01$). Production of IL-8 increased gradually to a maximum after 48 or

72 hours. Spontaneous production of IL-8 increased more in 20 Gy-irradiated cells than 10 Gy cells after 6 and 24 hours ($p < 0.01$), but increased more in 10 Gy cells than 20 Gy cells after 48 and 72 hours ($p < 0.01$). The production of IL-8 stimulated by IL-1 beta increased more in 10 Gy cells than 20 Gy cells 24 hours later ($p < 0.01$). IL-6 and IL-8 production differed in the response to irradiation. Our data suggest that bidirectional communication between the immune system and glioma cells changes after radiotherapy.

JT NEUROLOGIA MEDICO-CHIRURGICA
AD Department of Neurosurgery, Niigata University.
LA Eng
AB The expression of the intercellular adhesion molecule-1 (ICAM-1) and neural cell adhesion molecule (NCAM) by glioma cell lines was investigated. The effects of interferon (IFN)-gamma or irradiation on the expression was also assessed. Two glioma cell lines showed more than 75% NCAM-positive cells. After treatment with IFN-gamma or irradiation, another three cell lines were induced to show more than 50% positive cells. Three glioma cell lines showed more than 50% ICAM-1-positive cells. After treatment with IFN-gamma, another two cell lines were induced to show more than 50% positive cells. After treatment with irradiation, one more cell line was induced to show more than 50% positive cells. ICAM-1 and NCAM expression by glioma cell lines is susceptible to modulation by IFN-gamma or irradiation.

TI [Radiation hormesis, radiation stimulation or hyperfunctional effect of ionizing radiation? (letter)]

SO Radiats Biol Radioecol 1993 Sep-Oct;33(5):760-4

JT RADIATIONNAIA BIOLOGIIA, RADIOECOLOGIIA

LA Rus For

AB The term "radiation hormesis" is thought of unsatisfactory one because it is difficult to define such concepts as "benefit", "harm" or "contributory" with respect to irradiation of biological species. The term does not take into account a fact that large doses stimulate the same biological processes and functions as low ones. The definition of the effect of radiation stimulation as physiological hyperfunction response of biological object to ionising radiation is proposed.

TI Childhood cancer around nuclear installations.
SO Eur J Cancer Prev 1994 Jan;3(1):15-21
JT EUROPEAN JOURNAL OF CANCER PREVENTION
AD Department of Pathology, Lancaster Moor Hospital, UK.
LA Eng
AB There is an increased incidence of childhood cancer, particularly lymphocytic neoplasia, in children who live close to nuclear installations. Possible causes are radiation-induced germ line mutations in occupationally exposed parents, or radiation-induced somatic mutation in the developing cells of the fetus or child due to increased environmental exposure. An alternative possibility is that the socioeconomic characteristics of the communities lead to an altered response to infection in childhood and this increases the risk of lymphocytic neoplasia in particular. For sites other than Sellafield in

the UK, the evidence linking childhood cancer to radiation is unconvincing and it is possible that the increase is entirely due to the social characteristics of the communities. In Seascale, a village close to Sellafield, however, the increase is more marked and it is unlikely that social factors alone can explain the change. Furthermore, the environmental discharges from Sellafield are much higher than from other sites, and approach levels which could have a measurable effect on cancer incidence. In spite of a great deal of epidemiological investigation, no clear answer is available. It is argued that in order to solve the problem we must use new knowledge from molecular genetics and measure the rate of somatic mutation in those who work in the nuclear industry and in those who live nearby.

LA Eng
AB In L5178Y mouse lymphoblasts, ionizing radiation-induced mutant frequencies were dramatically higher when the genetic marker analyzed was heterozygous (tk+/tk-) than when hemizygous (tk+/tk0 or hprt+/hprt0). In contrast, base-change mutagens induced similar mutant frequencies at heterozygous and hemizygous loci. These results indicate that the majority of radiation-induced mutants harbor multilocus lesions, and that these mutants are poorly recovered when the target gene is in a hemizygous chromosomal region. Dose-rate dependence of radiation-induced mutant frequency was demonstrated at the heterozygous tk locus but not at the hemizygous hprt locus; in a cell line deficient in the rejoining of DNA double-strand breaks (DSBs), no dose-rate dependence was observed for either locus. The majority of TK-/- mutants, whether spontaneous or induced by X, alpha-particle or UV radiation, or by photosensitization, showed loss of the entire active tk allele. The percentage of TK-/- mutants exhibiting inactivation of galactokinase, encoded by the neighboring gk gene, was high in UV

repair-deficient cells exposed to UV radiation and in DNA DSB repair-deficient lines exposed to X radiation. Thus the presence of unrepaired DNA lesions, whether DSBs or pyrimidine dimers, appears to result in an increase in the percentage of mutants harboring multilocus lesions.

AB OBJECTIVE: To clarify the effects of ionizing radiation and to dispel

fear associated with the use of radioactivity in medical diagnosis and therapy. DESIGN: Studies of populations in geographic areas of increased cosmic radiation and high natural background radiation, radiation-exposed workers, patients with medical exposure to radioactivity, and accidental exposure are reviewed. RESULTS: No reproducible evidence shows harmful effects associated with increases in background radiation of 3 to 10 times the usual levels. American military personnel who participated in nuclear testing had no increase in leukemia or other cancers. Among 22,000 patients with hyperthyroidism treated with ¹³¹I (mean dose, 10 rem), no increased incidence of leukemia was found in comparison with 14,000 similar patients who received other treatment. A 20-year follow-up of 35,000 patients who underwent ¹³¹I uptake tests for evaluation of thyroid function revealed that those studied for other than a suspected tumor had only 60% of the thyroid cancers expected in a control group. Although early studies showed that high exposures to miners to radon and its daughters resulted in a substantial increase in lung cancer, no evidence exists for an increase in lung cancer among nonsmokers exposed to increased radon levels in the home. CONCLUSION: Perhaps the association of radiation with the atomic bomb has created a climate of fear about the possible dangers of radiation at any level; however, no evidence indicates that current radiation exposures associated with medical usage are harmful.

AB For treatment of radiation accident victims, procedures for handling trauma patients must be modified to ensure proper care and prevent contamination of hospital facilities and personnel. The radiation accident management plan should be instituted in advance. Exposure and contamination victims are treated differently. Exposed patients have

sustained either partial or whole-body exposure but do not carry radioactive material; contaminated patients have also been exposed, but they have radioactive material either externally or internally and thus are continually exposed to radiation until the contaminant is removed. The treatment area and personnel must be protected with use of isolation, clean transfer techniques, and appropriate attire. After clothing has been removed, the patient's medical condition is assessed, stabilized, and treated. Samples from the affected areas, eyes, nose, and mouth are obtained for analysis and planning definitive treatment. For external contamination, the skin is washed with normal saline or mild detergent. Treatment of internal contamination is based on the isotopes involved and may include saturation of the crucial organ, dilution therapy, isotope displacement, or use of chelating agents. After a survey to ensure that no residual contamination remains, the patient is transferred to a care unit. Effects of exposure are seen over periods ranging from days to weeks to years, depending on the total dose received. Knowing the dose allows clinicians to predict what effects may ultimately occur.

 AB There is a notable lack of scientific consensus on whether electric and
 magnetic fields (EMF) constitute a health risk in need of systematic
 control. Even those who see EMF as a public problem, share few
 assumptions about the type of problem it represents, whether serious
 risks to health are involved, or about the collective action it
 warrants. In the absence of conclusive scientific evidence, the
 interpretations of various social and political institutions have moved
 into the foreground, each bringing a different perspective to the issue
 and a unique way of accommodating the ambiguity surrounding the question
 of health effects. The result is a confusing mixture of warnings and
 reassurances, of calls for more study, or for immediate action, that
 distinguishes the EMF issue from other, better-defined environmental
 risks. While much of the discussion of EMF has focused on the synthesis
 and assessment of experimental and epidemiologic research on health
 effects, this paper explores the diversity of institutional
 interpretations to shed some light on the social and political responses
 to the issue and how these might shape its future in public policy. The
 paper concentrates on the selected norms and practices of three
 institutions, centrally involved yet differing in their interpretations:
 the scientific community, the legal system, and public bureaucracy. The
 disparities that form among the interpretations of institutions faced
 with ambiguous evidence and ill-formed problem definitions can lead to
 tensions and a search for alternative means of resolving contested
 meanings.

 LA Eng
 AB Theoretical models proposed to date have been unable to clearly predict
 biological results from exposure to low-intensity electric and magnetic
 fields (EMF). Recently a predictive ionic resonance model was proposed
 by Lednev, based on an earlier atomic spectroscopy theory described by
 Podgoretskii and Podgoretskii and Khrustalev. The ion parametric
 resonance (IPR) model developed in this paper corrects mathematical
 errors in the earlier Lednev model and extends that model to give
 explicit predictions of biological responses to parallel AC and DC
 magnetic fields caused by field-induced changes in combinations of ions
 within the biological system. Distinct response forms predicted by the
 IPR model depend explicitly on the experimentally controlled variables:
 magnetic flux densities of the AC and DC magnetic fields (Bac and Bdc,
 respectively); AC frequency (fac); and, implicitly, charge to mass ratio
 of target-ions. After clarifying the IPR model and extending it to
 combinations of different resonant ions, this paper proposes a basic set
 of experiments to test the IPR model directly which do not rely on the
 choice of a particular specimen or endpoint. While the fundamental
 bases of the model are supported by a variety of other studies, the IPR
 model is necessarily heuristic when applied to biological systems,
 because it is based on the premise that the magnitude and form of
 magnetic field interactions with unhydrated resonant ions in critical
 biological structures alter ion-associated biological activities that
 may in turn be correlated with observable effects in living systems.

AB Progress in quantitative clinical radiobiology has improved the possibilities for rational design of new radiotherapy schedules. This paper reviews some general problems in calculating the required number of patients in a trial with a radiobiological rationale. Three such rationales are considered: dose escalation, hyperfractionation, and accelerated fractionation. One crucial factor in calculating the size of a trial is the steepness of the dose-response curve for both tumors and normal tissues, and literature data on this are reviewed. It is concluded that fairly large trials, typically comprising 300 or more patients, are necessary, unless efficient stratification of the patients is possible according to the risk for some specific type of recurrence. Such stratification may be possible either according to clinico-pathological characteristics or to the results from predictive assays.

A Guide to Environmental Resources on the Internet
by
Carol Briggs-Erickson
and
Toni Murphy

Version 1.0 Compiled September 1993 - December 1993.

Welcome to A Guide to Environmental Resources on the Internet by Carol Briggs-Erickson and Toni Murphy. This is a guide to resources of an environmental nature which can be found on the Internet and was written to be used by researchers, environmentalists, teachers and any person who is interested in knowing and doing something about the health of our planet. The guide is arranged alphabetically by subject and then by the Press SPACE for more, q to quit Internet tools used to locate those resources. It is not intended to be an instructional manual on the use of the tools. The authors would recommend the books "The Whole Internet" by Ed Krol, "The Internet Companion" by Tracy LaQuey, or some of the guides that are available by anonymous ftp, such as "The Big Dummy's Guide to the Internet" (which is located at <ftp://unix.hensa.ac.uk/pub/uunet/pub/linguistics/bigdummysguidetotheinternet.Z>) for learning the use of the tools.

Access to this guide is available via the "Clearinghouse for Subject-Oriented Internet Resource Guides", a joint project of the University of Michigan Library and the School of Information and Library Studies. Access points:

```
anonymous FTP:
  host: una.hh.lib.umich.edu

1. Introduction

This guide is arranged primarily by subject, but since there are a number of resources that reside within databases that are available to the public covering the whole scope of environmental concerns, and a number of

Press SPACE for more, q to quit agencies that deal with environmental standards and

regulations, we decided to give these agencies and databases their own sections. We also found some resources that deal with the ecology of one geographic area. These were also put into a separate section. Everything else that we found, we felt could be placed under one or two subject headings except for the resources found in the many online catalogs available by gopher and telnet. Time constraints kept us from listing the catalogs by subject, but each catalog included contains at least 50 resources pertaining to three or more of our subject topics. We searched for our resources using gopher, telnet, archie, veronica, ftp, world wide web and wais. We did not find much of relevance using www subject entry points; nor were there a great number of wais documents. What we did find using www and wais is listed under each subject.

Some of the files mentioned in this guide are in the GIF format. If you are not using Mosaic or other software that allows viewing of these image files, consult the FAQ documents on accessing software conversion programs.

Press SPACE for more, q to quit(URL:
file://bloom-picayune.mit.edu/pub/usenet-by-group
/alt.answers/pictures-faq/part3)

2. Major environmental organizations and networks.

2.1 Consortium for International Earth Science Information Network (CIESIN)

Contains environmental policies, conference information, full text of world treaties, WAIS searchable environmental sources.

Audience: Primarily earth scientists, but contains resources of interest to environmentalists, and researchers, educators.

Rating: A good source for general issues; many of the documents are available from other Internet sources, e.g. EPA, UNCED.

```
gopher> gopher.ciesin.org
```

Press SPACE for more, q to quit

The CIESIN Catalog Services at Polytechnic University is searchable by:

```

```

2.2 Environmental Protection Agency (EPA)

Press SPACE for more, q to quit
covering a

The EPA maintains searchable databases

wide range of environmental issues in its "Online Library System". In addition to a main, national catalog of citations, there are searchable databases on hazardous wastes, clean lakes, and environmental financing. The publication, Access EPA, is also available.

Audience: Researchers, consumers, environmentalists.

Rating: Very comprehensive coverage, large dataset.

```
telnet> epaibm.rtpnc.epa.gov
login: public
menu: 1
```

In addition, the EPA is developing a gopher site covering topics such as agriculture, air, water, land, and related environmental topics.

```
gopher> futures.wic.epa.gov
```

or

Press SPACE for more, q to quit

```
gopher> North America
```

USA

Washington DC

USA Environmental Protection Agency

The EPA Office of Air Quality Planning and Standards also maintains a network of bulletin boards. (See 3.2)

2.3 EcoNet

Large, fee-based network comprised of many environmental discussions, reports, articles, and documents. Resources include U. S. EPA press releases and weekly transcripts of "Living on Earth" (NPR's Environment news program.) Large, Worldwide coverage and membership. Some materials are archived and available via ftp.

Press SPACE for more, q to quit
econet-info@igc.apc.org for
information

Send a blank message to:

```
anonymous ftp> igc.apc.org
/pub/econet_brochure
```

```
gopher> igc.apc.org (in development)
```

There are many discussion groups relating to environmental issues. Just a few include:

en.alerts
en.events
en.climate
en.energy
en.recycle
en.toxics
sc.natlnews (Sierra Club)
en.cleanair

Press SPACE for more, q to quit 2.4 Environmental Resources Information
Network (ERIN)

Network linking the Australian Nature Conservation Agency, the Australian Heritage Commission, the Commonwealth Environment Protection Agency, and the Department of the Environment, Sport and Territories. Main focus is on endangered species, vegetation, and area studies. Resources include data sets, images (GIF), international agreements, legislation and conference information. Emphasis on the Australian environment; some world coverage.

gopher> kaos.erin.gov.au

URL: <http://kaos.erin.gov.au:80/erin.html>

3. Subject resources

3.1 Acid rain

Press SPACE for more, q to quit

3.1.1 Telnet

3.1.1.1 Classroom Earth

Classroom Earth (An environmental education resource made possible by a grant from NASA) has an Acid Rain Online Lab for teaching about the study of acid rain. Water sample data is entered by groups; the data can be downloaded and compared.

telnet> classroom_earth.ciesin.org 2010
hit RETURN when connected

(For additional resources on acid rain, consult section 3.6 Environment (general).)

3.2 Air pollution

3.2.1 LISTSERVS:

Press SPACE for more, q to quit

SAFETY@UVMVM

This is a group which discusses safety in all aspects. It is relevant here on topics of waste disposal (burning, etc.), and chemical hazards.

REACTIVE-L@VM1.MCGILL.CA

This is a moderately active discussion group dealing with short-lived air pollutants.

3.2.2 EPA bulletin boards:

telnet> ttnbbs.rtpnc.epa.gov

Some available bulletin boards

CAAA - Clean Air Act Amendments

EMTIC - Emission Measurement Technical Information Center emission test methods and testing information)

Press SPACE for more, q to quit AIRS - Air quality and emissions

BLIS - Compilation of air permits from air pollution control agencies.

NATICH - Information submitted by EPA, state and local agencies about air toxics programs

COMPLI - Stationary source and asbestos compliance policy

CHIEF - Latest information on air emission inventories and emission factors

ATPI - Current course offerings on air pollution

3.2.3 FTP sites:

3.2.3.1 nic.cic.net

There are many good documents in the "e"
directory at this site having to
do with pollution and other environmental
Press SPACE for more, q to quit issues,useful to researchers.

```
ftp> nic.cic.net
/pub/nircomm/gopher/e-serials/alphabetic

/e/env-link/unocal.pollution.Z
```

URL:file://nic.cic.net/pub/nircomm/gopher/e-serials
/alphabetic/e/env-link

3.2.3.2 unix.hensa.ac.uk

The pollution datasets at this site are of value
to researchers and environmental scientists and
legislators.

```
ftp> unix.hensa.ac.uk
Press SPACE for more, q to quit /pub/statlib/datasets/pollution
```

URL:file://unix.hensa.ac.uk/pub/statlib/datasets/pollution

3.3 Alternative energy

3.3.1 LISTSERVS:

HYDROGEN-L@URIACC.URI.EDU

Discusses hydrogen as an alternative energy
source. Some very lively discussions, but
tends to be scientist oriented.

ENERGY-L@TAUNIVM

Good discussion of alternative energy.

AE@SJSUVM1.SJSU.EDU

This alternative energy discussion group is
intended to provide a forum to discuss
the current state of the art and future

directions of alternative energy sources
Press SPACE for more, q to quit that are renewable or
sustainable.

3.3.2 Newsletters:

3.3.2.1 Wind Energy Weekly, newsletter. For
free online subscription, e-mail Tom
Gray (Internet/Bitnet: tgray
@igc.apc.org)(EcoNet/PeaceNet:
tgray@igc)(UUCP:uunet!cdp!tgray). Also
available by anonymous ftp.

ftp> sunsite.unc.edu
/pub/academic/environment/alternate-energy
/miscellaneous/wind-energy-weekly

URL:file://sunsite.unc.edu/pub/academic/environment
/alternate-energy/miscellaneous/wind-energy-weekly

3.3.3 FTP and gopher:

Press SPACE for more, q to quit
and

3.3.3.1 Center for Renewable Energy

Sustainable Technology (CREST)

This is an (emerging) educational resource
center providing services and education focusing
on renewable energy, energy efficiency, the
environment, and sustainable development.

ftp> ftp.digex.net
/pub/crest

URL: file://ftp.digex.net/pub/crest

gopher and www access: in development

3.4 EcoSystems

Press SPACE for more, q to quit

3.4.1 LISTSERVS:

ECOSYS-L@vm.gmd.de
Ecosystem theory in German

ECOLOG-L@UMDD.UMD.EDU
Discussion group of the Ecological Society
of America. Includes grant information,
job postings, general news and discussion
of ecological topics. Very active group.

ECOLOGY@EMUVM1
Politics and the environment. Discusses
government policy, EPA rulings, etc.

3.4.2 FTP:

```
ftp> pencil.cs.missouri.edu

3.6.2.4 LTER - (Long Term Ecological Research gopher)

Includes datasets, conferences, bibliographies, meeting abstracts, etc. Good for researchers, and environmental scientists.

```
gopher> lternet.edu
```

Press SPACE for more, q to quit

3.6.2.5 CICNet gopher

Access to newsletters, keyword searching of databases, EcoNet documents, etc. Resource for researchers, environmental scientists, oceanographers and others.

```
gopher> gopher.cic.net
```

3.6.3 Telnet:

3.6.3.1 PENPages

There are many good documents on the environment here that would be useful to teachers, researchers and environmentalist.

```
telnet> psupen.psu.edu
      login: your two-letter state code
      keyword search: environment
```

Press SPACE for more, q to quit

3.6.3.2 Envirolink Network

There are some great bibliographies, statistical resources and other documents relevant for researchers and environmentalists at this site.

```
telnet> envirolink.org
      login: gopher
```

3.6.3.4 OLS database

The EPA mainframe is open 24hrs/day, except from 8:00 PM Sunday to 7:00 AM Monday (EST). The OLS database contains book citations, federal agency technical reports, indices, audiovisual materials, maps, journals and other documents. The National Catalog, Hazardous Waste, and Lakes databases can be searched by single keyword. They allow you to combine terms in a boolean type search.

Press SPACE for more, q to quit

```
telnet> epaibm.rtpnc.epa.gov
      select Public Access
      select OLS
      select 1
```

3.6.3.5 EnviroNet

This is a resource for space environment information. It contains handbook sections which are good resources for teachers and environmental researchers.

```
telnet> envnet.gsfc.nasa.gov
```

```
login: envnet  
passwd: henniker
```

3.6.3.6 SciLink

There are two discussion groups that are relevant here, "environment" and "earth." You can also send private messages to

other SciLink users. This is a good resource for educators, environmentalists and students k-12.

```
telnet> scilink.org  
login: guest  
passwd: guest
```

ACADEMIC AMERICAN ENCYCLOPEDIA

RADIATION

The term radiation refers both to the transmission of energy in the form of waves, and to the transmission of streams of atomic particles through space.

Any ENERGY that is transmitted in the form of waves is some kind of ELECTROMAGNETIC RADIATION. Each kind is distinguished by its wavelength, or frequency (see WAVES AND WAVE MOTION). All kinds of electromagnetic radiation obey the same physical laws (see BLACKBODY RADIATION), they all travel at the speed of LIGHT, and when they fall on a surface they exert a pressure proportional to the net flux of energy divided by the speed of light. Roughly in the order of decreasing wavelength, the kinds of electromagnetic radiation are RADIO waves, radiant heat energy (see HEAT AND HEAT TRANSFER) and MICROWAVES, INFRARED RADIATION, light, ULTRAVIOLET RADIATION, X RAYS, and GAMMA RAYS.

Many forms of particulate radiation are possible. In the phenomenon of RADIOACTIVITY, alpha radiation (helium nuclei; see ALPHA PARTICLE) and beta radiation (ELECTRONS) are observed, along with gamma rays. Very energetic particles from outer space are called COSMIC RAYS. Any particulate or electromagnetic radiation that can dissociate atoms into ions (see ION AND IONIZATION) is called ionizing radiation. Such radiation can produce harmful effects in organisms, and it is of concern in matters dealing with NUCLEAR ENERGY (see FALLOUT; POLLUTION, ENVIRONMENTAL; RADIATION INJURY; RADON). It is also widely used in medicine, however, for both diagnosis and therapy (see NUCLEAR MEDICINE; RADIATION THERAPY; RADIOGRAPHY; RADIOLOGY), as well as being widely employed in scientific research (see ACCELERATOR, PARTICLE SYNCHROTRON RADIATION).

ACADEMIC AMERICAN ENCYCLOPEDIA

RADIATION INJURY

When living tissue is irradiated, the tissue's molecular structure is disrupted, triggering a chain of events that can destroy living cells or produce chromosomal damage or other injury. The biological effects on the human body of large amounts of radiation are well known, due in large part to studies of the 76,000 survivors of the atomic bombings in Japan who have been closely monitored for over 40 years. The possible deleterious effects of low-level radiation are still unclear, but a variety of studies suggest that low-level radiation exposure may be more dangerous than previously thought. Furthermore, recent studies have shown a statistically significant link between cancer and low-level electromagnetic fields generated by common appliances and power lines, although no causal relationship has yet been found.

Types of Radiation Exposure

Every person on Earth is exposed to some form of radiation each day. In the United States, 82 percent of radiation exposure is from natural sources, such as cosmic and solar rays producing gamma rays and alpha or beta particles. The radioactive element radium, which decays to the poisonous gas RADON, emanates from rocks, soils, and groundwater. The remaining 19 percent of radiation exposure is derived from man-made radiation. Everyday sources include medical X rays and radioactive sensors that activate household smoke detectors. Spent fuel, high-level wastes, and other radioactive by-products from nuclear reactors and weapon plants, which may be stored improperly due to lax safety practices or obsolete facilities, also contribute to radiation exposure (see NUCLEAR WASTE). In addition, high levels of radiation are created in the atmosphere after nuclear power plant accidents, such as those that occurred at Three Mile Island in Pennsylvania and CHERNOBYL in the Soviet Union, and fall-out from nuclear explosions.

The amount of radiation absorbed per gram of body tissue is expressed in RAD (radiation absorbed dose). The unit of measurement used to describe the expected biological effects from radiation exposure in human soft tissue is REM, or roentgen equivalent man. A dose of 10,000 rem is lethal

through damage to the central nervous system. A dose of 300 rem delivered to the whole body is lethal 50 percent of the time. Radiation injury is probable at doses between 300 and 100 rem.

ACADEMIC AMERICAN ENCYCLOPEDIA

RADIATION INJURY

Radiation Effects

The effects of radiation may be divided into four types: acute somatic effects, developmental effects, genetic effects, and late somatic effects. Acute somatic effects occur in individuals within days or weeks of their exposure. Injuries to the brain cause delirium and convulsions; damage of the eye lens results in cataracts; nausea and vomiting occur if the gastrointestinal tract is injured; damage to the ovaries or testes may cause sterility; and damage to the bone marrow affects the body's ability to fight infection. Depending upon the degree of irradiation, certain tissues, such as the bone marrow, the intestinal lining, or the skin, may be able to replace cells killed by radiation within a few days. The graying of hair by high doses of radiation, however, is permanent, providing evidence that above a certain dose level, pigment-producing cells are not replaced.

Developmental effects occur to unborn children of mothers exposed to radiation. A common consequence is brain damage or mental retardation, particularly if exposure occurs between the 8th and 15th week of gestation, when rapid development of fetal brain tissue occurs. Radiation exposure also may cause genetic mutations in adults that are carried through to children or later descendants.

Late somatic effects are injuries produced in an individual many years after exposure to radiation. The major late somatic effect is the development of various forms of cancer. A 1989 study by the National Research Council reports that even low doses of radiation pose a human cancer risk three to four times higher than previously estimated. The study reported that for each 100,000 persons receiving a single exposure of 10 rem, about 790 excess cancer deaths will result. A single exposure of 0.1 rem per year throughout a person's lifetime, equivalent to exposure from a single head and body CAT SCAN, may

contribute 550 excess deaths from cancer per 100,000 people. The estimated cancer risks for children exposed are about twice as large as those for adults.

ACADEMIC AMERICAN ENCYCLOPEDIA

RADIATION PRESSURE

Radiation falling on a surface exerts a pressure; its value is proportional to the net flux of energy divided by the speed of light. If a particle is traveling in an orbit around the Sun, solar radiation will appear to come from a position slightly shifted toward the direction in which the particle is moving, just as to a moving pedestrian raindrops appear to fall not vertically but from a direction tilted toward the direction in which the person walks. This displacement is an aberration of light (see ABERRATION, STELLAR) and causes a net retarding force to act on the particle (Poynting-Robertson effect) that will ultimately cause the particle to fall into the Sun.

ACADEMIC AMERICAN ENCYCLOPEDIA

RADIATION THERAPY

Radiation therapy, or radiotherapy, is a branch of RADIOLOGY used to treat CANCER. A patient is exposed to ionizing radiation in doses designed to kill a malignancy. Malignant tissues are more sensitive than normal tissues to radiation exposure and can be treated if they have not spread throughout the body and are not surrounded by normal tissue that is especially sensitive to radiation, such as the spinal cord. Sophisticated physical and biological techniques are used for radiation therapy, often accompanied by computer analyses (see NUCLEAR MEDICINE). A radiation therapist develops a treatment plan that permits the absorption of a fatal amount of radiation by all tumor cells but causes relatively minor damage to normal tissue. The usual mode of therapy is an external high-energy beam directed at the tumor site for a few minutes a day for 2 to 6 weeks, depending on the type of malignancy. X RAYS, gamma rays, and such isotopes as cobalt-60 and iodine-131 are often used.

OAK RIDGE NATIONAL LABORATORY

The Oak Ridge National Laboratory (ORNL) was founded (1943) by the U.S. government as part of the World War II MANHATTAN PROJECT to construct an ATOMIC BOMB. Located in Oak Ridge, Tenn., ORNL was engaged to develop safe, economic, and environmentally acceptable energy technologies for the future. It is operated by Martin Marietta Energy Systems, Incorporated, under a contract with the U.S. Department of Energy, and is also supported by other government agencies. Its staff numbers approximately 5,000 persons. Formerly called the Clinton Laboratories, ORNL received its current name in 1948. Bibliography: Johnson, C. W., and Jackson, C. O., City behind a Fence: Oak Ridge, Tennessee 1942-1946 (1981).

PT CONGRESS (CON).
LG English (EN).
AB A workshop on the Human Health Impacts of Halogenated Biphenyls and
Related Compounds was held to assess the state of current research on
these chemicals and to make recommendations for future studies.
Participants discussed results from laboratory animal experiments on
PCBs, PBBs, dioxins, and dibenzofurans which demonstrate a common
mode of toxicological action while also revealing large variations in
toxicological potency both within and between these chemical
families. These variations demonstrate the importance of
congener-specific analyses in future studies of effects of exposure
to these compounds. Results from epidemiological studies of
environmentally exposed adult and pediatric populations from the
U.S., Japan, and Taiwan and occupationally exposed *cohorts* from
around the world were considered. It was concluded that available
evidence did not demonstrate serious adverse effects such as cancer,
in exposed adult *cohorts* but did provide indications of possible
neurobehavioral effects in children exposed in utero. In addition,
workshop participants described newly developed markers of exposure
and techniques for assessing endocrinological, immunological, and
neurological effects and suggested these be applied to
epidemiological studies of the effects of polyhalogenated compounds.
Other recommendations included identification of other *cohorts* and
development of a large *registry* of exposed individuals; performance
of detailed studies of reproductive function and outcomes in exposed
populations; and follow up of neurobehavioral effects in offspring of
exposed women. Author-abstract.

College of Health Sciences, Dar es Salaam, Tanzania.

JT CENTRAL AFRICAN JOURNAL OF MEDICINE.

AB The Tanzania Cancer *Registry* at Muhimbili Medical Centre, Dar es Salaam, Tanzania was reviewed for squamous cell carcinoma of the skin in non-albino African subjects. The data was analysed for age, sex, site and predisposing factors. Our results were then compared with studies previously carried out in Tanzania, elsewhere in Africa and also on Blacks in America. Squamous cell carcinoma of the skin was found to be a common malignancy, and the commonest skin cancer. Its peak was in the 40-49 years age group though it could occur in children under five years of age. The most affected site was the lower limb, followed by the head and the neck. The penis in the male and the vulva in the female were the third most affected sites. The scalp and the lip were more affected in females than males. Chronic trauma, chronic ulcers, and scars were the main predisposing risk factors to the lower limb and the scalp, while ultra violet *radiation* to the head and neck, and smegma of the uncircumcised penis were thought to be predisposing risk factors. Author-abstract.

JT AMERICAN JOURNAL OF INDUSTRIAL MEDICINE.

AB Health care workers may be occupationally exposed to known and suspected teratogens including viruses, anesthetic gases, sterilants, mercury, and *x-radiation.* To assess the risk of congenital defects among offspring of health care workers, we analyzed parental occupational histories for 4,915 case babies with congenital defects, registered during the years 1968-1980 by the Metropolitan Atlanta Congenital Defects Program (MACDP) *registry,* and for 3,027 control babies born without defects during the same period. Offspring of mothers employed in a nursing occupation during the periconceptional period had a modest excess risk of having at least one congenital defect (relative risk `RR: = 1.42; 95% confidence interval `CI: 1.06-1.88); the offspring were at statistically significant increased risk of having anencephaly or spina bifida (RR = 2.00; 95% CI 1.01-4.30), coarctation of the aorta (RR = 2.06; 95% CI 1.10-3.82), genital system defects (RR = 1.61; 95% CI 1.03-2.53), and urinary system defects (RR = 3.43; 95% CI 1.41-8.34). These associations were not confounded by maternal age, education, or alcohol consumption. Offspring of mothers employed in administrative or

clerical jobs in the health care industry also had a modest excess risk of defects (RR = 1.35; 95% CI 0.96-1.90), including a statistically significant excess risk of limb defects. We also found associations between neural tube defects and potential exposure to anesthetic gases and to *x-radiation,* but each association was based on only three case babies of potentially exposed parents. We found no associations between defects and paternal health care employment, except for a few individual defects, and these were based on small numbers of exposed subjects. Only one of five previous studies reviewed found an increased risk of congenital defects among offspring of nurses, but three of the four negative studies had substantially smaller sample sizes than the present study. Detection bias may be a possible explanation for the apparent excess risk of certain defects among offspring of nurses. Author-abstract.

JT *RADIATION* AND ENVIRONMENTAL BIOPHYSICS.

AB Age-specific and cumulative mortality rates are presented for different cancer sites from 1970 until 1988 for the 11 individual federal states of West Germany (FRG). Sex- and age-specific evaluations are performed and temporal and regional trends in mortality from different cancer sites are revealed. In the FRG there is no comprehensive cancer *registry* with national coverage for recording cancer patients of all ages (nationwide incidence rates are available only for childhood cancers). Therefore, in view of the lack of a nationwide cancer *registry* the importance of long-term cancer mortality studies for health policy is emphasized. Methodological aspects of certification regulations and classification of cancer sites are discussed. Author-abstract.

JT AUSTRALIAN AND NEW ZEALAND JOURNAL OF OPHTHALMOLOGY.

AB The aims of the Australian Corneal Graft *Registry* are to collect and collate statistical information on the practice of corneal transplantation around Australia, to identify risk factors for corneal graft failure, and to provide information on graft and visual outcome. The current report encompasses analyses performed on 3608 corneal grafts (96% penetrating and 4% lamellar) entered into the

Registry between May 1985 and July 1991. Sixty-four per cent of grafts have undergone one or more rounds of follow-up by the 189 contributing surgeons and 110 additional referring practitioners: five-year Kaplan-Meier graft survival for penetrating and lamellar grafts is 72% and 84%, respectively. The main indications for penetrating keratoplasty were keratoconus (31%), bullous keratopathy (25%), history of failed previous graft (14%), corneal scars and opacities (11%), and corneal dystrophies (7%). The most common reasons listed for failure of penetrating grafts were rejection (33%), glaucoma (11%), non-viral infections (10%), endothelial cell failure (8%) and herpetic infection (7%). In 19% of cases, the reason for graft failure was unclear. The main indications for lamellar keratoplasty were pterygium (32%), thinning, necrosis or ulceration from old *beta-radiation* therapy for pterygium (17%), and scleral ulcers, necrosis, ectasia, perforations or melts (29%). The most common reasons for the failure of lamellar grafts were corneal melting (43%) and sloughing of the graft (29%). Among the factors that influenced the survival of penetrating corneal grafts to a significant extent ($P < 0.05$) in univariate analysis were: the centre effect, indication for graft, graft number, a history of pregnancy or blood transfusion, inflammation before or at the time of graft, corneal vascularisation at the time of graft, a history of raised intraocular pressure, the donor cornea procurement source, the death to donor cornea enucleation time, graft size and large degrees of oversizing, lens status and the type of intraocular lens in situ. In the postoperative period, risk factors for failure included early removal of graft sutures, neovascularisation of the graft, herpetic recurrences in the graft and the occurrence of rejection episodes. The variables that best predicted penetrating corneal graft failure in Cox propore of graft, and a postoperative rise in intraocular pressure.(ABSTRACT TRUNCATED AT 400 WORDS). JT CLINICAL TRANSPLANTS.

AB The number of allogeneic BMTs performed worldwide continues to increase. In addition, the characteristics of patients, donors, and selected treatments are changing. In BMT for leukemia during the 1980s there was a marked increase in transplants for early disease, the use of unrelated donors, and utilization of preparative regimens without *radiation.* Although treatment-related mortality declined during this period, there was only a modest decrease in relapse rates, indicating the need for more effective antileukemia strategies. The IBMTR collects data from many centers, and, as a consequence, it is uniquely suited to examine clinical situations in which patient accrual at a single institution would be insufficient

for a study to be performed. In such analyses, BMT was shown to be an effective treatment for Ph1-positive ALL. Patients tended to have earlier relapses and lower probabilities of LFS than Ph1-negative ALL but the differences were not statistically significant. BMT was also shown to be effective in patients with acute leukemia failing to ever go into remission, most of whom would die within the first 6 months following diagnosis. The IBMTR is a premier example of international scientific collaboration. Its success is a consequence of the desire of investigators throughout the world to combine their clinical data for statistical analysis in order to accelerate and improve patient care. Author-abstract.

JT JOURNAL OF CLINICAL EPIDEMIOLOGY.

AB The mortality pattern among 999 Danish patients who had been subjected to angiography of the carotid artery with the alpha-ray emitting X-ray contrast media Thorotrast during the period 1935-47 was assessed by record linkage with the National Death *Registry* through 1989. Standardized mortality ratios (SMR) were calculated relative to the general population. The overall SMR was increased by 18 times during the first 3 years after Thorotrast injection. This rate reflects the often serious, underlying neurological conditions for which angiography was performed, however, mortality was increased by 3-4 fold even for the follow up period after the first 3 years. The increase in mortality was evident for all categories of cause of death, the SMR being 11.1 (95% confidence interval (CI) 7.1-16.4) for cirrhosis of the liver, 4.7 (4.1-5.3) for cancer, 1.6 (1.3-1.9) for cardiac disease, 3.3 (2.6-4.2) for cerebrovascular diseases, 3.9 (3.3-4.5) for other natural causes, and 4.4 (3.4-5.6) for violent causes (including suicides). The SMR was generally related positively to young age at injection, to time since injection, and to the amount injected. The excess mortality can be explained only partially by underlying neurological conditions and by diseases known to be induced by Thorotrast (cirrhosis and cancer of the liver, leukaemia and other haematological diseases), and it is suggested that unspecific effects induced by the *alpha-radiation* of Thorotrast may have contributed. Author-abstract.

JT CANCER.

AB BACKGROUND. Older patients with cancer are less likely to receive definitive therapy, but the reasons for this are unclear. METHODS. All people aged 65 years or older living in six counties in New Mexico and diagnosed with breast, prostate, or colorectal cancer

between May 15, 1984 and May 15, 1986 (N = 669) were interviewed to obtain information on demographics, socioeconomic status, functional status, social support, other medical conditions, and cognitive status. Cancer treatment information was obtained from the New Mexico Tumor *Registry.* RESULTS. In univariate analyses, the following variables were associated significantly with nonreceipt of definitive therapy for cancer: advanced age, impairment in activities of daily living, low physical activity, decreased mental status, impaired access to transportation, and poor social support. In a multivariate analysis with the above variables along with measures of comorbidity, only advanced age and decreased mental status remained significant predictors of nonreceipt of definitive surgery, whereas the effects of impaired access to transportation and low physical activity remained relatively large but no longer were statistically significant. When receipt of surgery and receipt of *radiation* therapy were considered separately, older age, limited access to transportation, impaired functional status, and impaired mental status all significantly predicted nonreceipt of *radiation* therapy, but not surgery. CONCLUSIONS. There is a decline with age in the percentage of adults with cancer who received definitive therapy independent of other potentially explanatory factors such as comorbidity. In

AB The exciting new method of ablation of accessory pathways using radiofrequency current applied by catheters will dramatically change our therapeutic decisions in these patients in the near future. This brief survey reviews the existing literature about the risk of the disease as well as of the procedure of catheter ablation. From these data, the risk of sudden death appears to be extremely low in asymptomatic Wolff-Parkinson-White (WPW) individuals. Side effects of catheter ablation may result from the invasive procedure as well as from *radiation* exposure (the latter to the patient as well as to operating physicians). While the complication rate in experienced centers is extremely low, a multicenter *registry* of the success and complication rate is urgently needed in view of the many centers starting with catheter ablation. Based on a subjective benefit-to-risk analysis, asymptomatic WPW individuals should be offered catheter ablation only under special circumstances (high risk profession, athletes, family history of sudden death). On the other hand, catheter ablation need not be and should not be considered generally in asymptomatic individuals with WPW pattern. Finally, this author cannot imagine that the energy, time, and money spent for mass screening and eventual catheter ablation of asymptomatic WPW individuals with its attending risks can be outweighed by the potential benefits for these asymptomatic individuals.

JT PUBLIC HEALTH REVIEWS.

AB Gardner et al. (Br Med J 1990; 300: 423-429) reported a high relative risk for childhood leukemia among children, aged 0-24 years at time of diagnosis, born to fathers employed at the Sellafield nuclear plant in the U.K. As a result we looked for spatial and temporal trends of childhood and young adult leukemia in the Negev, where a nuclear plant has been in operation since 1960. We divided the Negev into an Eastern part where plant employees are likely to live, and a Western part where this is quite unlikely. Reported leukemia cases were provided by the Israel Cancer *Registry* for the age group 0-24, and for the period 1960-1985. We checked this file against data obtained from the hospitals in the area. We added 6 more cases in the Eastern Negev, none in the Western Negev, and none of the reported cases was discarded. There was a total of 192 cases, of which 52% were acute lymphatic leukemia. Jewish and Bedouin children were studied separately. Among Jewish children the average annual incidence rate for the Eastern Negev was 2.76/100,000, the Western Negev 3.51. Over time the leukemia rates were consistently higher in the Western Negev among children aged 0-9 years, which holds especially for acute lymphatic leukemia. There was a sudden increase among girls born during the period 1970-1979 in the northern part of the Western Negev, which was not noticed among boys. No excess cases were found in the small towns around the plant. Author-abstract.

JT HORMONE RESEARCH.

AB There is growing concern about the oncogenic potential of growth hormone (GH) used therapeutically. In rat experiments, a variety of malignant tumours haremainns controversial. There is a school of thought that black patients and younger patients have a biologically more aggressive disease. We analyzed the survival of 914 patients (867 whites and 47 blacks) with localized adenocarcinoma of the prostate treated with external beam irradiation from the Connecticut SEER Tumor *Registry* data base. Patients were treated from 1973-1987, and those with Stages A1, A2 and D2 were excluded. Patients ≤ 60 years of age had a 5-year survival rate of 72% compared to 61% for those > 60 years of age ($p = 0.06$). When stratified by race, white patients had a 63% 5-year survival rate versus 47% in black patients ($p = 0.02$). When analyzed by race and age, and age-race interaction was noted. Although younger whites fared better than older whites, 77% versus 61% survival at 5 years (p

= 0.02), younger blacks fared worse than older blacks, 31% versus 52% survival at 5 years ($p = 0.21$). Blacks, on average, presented at an earlier age than whites, 65 years versus 69 years ($p = 0.001$). Both races had similar stage and similar grade of disease. In older patients, both races presented with similar stage and grade of disease and had similar survival. However, in the younger age group, black patients presented with similar grade, but higher stage disease than whites. This may explain the worse survival in young blacks compared to young whites, 31% versus 77% at 5 years ($p = 0.007$). Multivariate analysis revealed that, even controlling for stage and grade, blacks still fared worse than whites. Increased age was associated with decreased survival in whites but increased survival in blacks. Author-abstract.

19

AU Ragnarsson-Oldinga. There was an increased, but nonsignificant, incidence of other cancers, based on two cases (one pinealoma and one Hodgkin's disease) occurring among those aged 15-24 years during 1984-90. This was not observed in the younger age group or in previous years. For the immediately surrounding area--that is, the county districts of Allerdale and Copeland excluding Seascale and in the remainder of Cumbria--there was no evidence of an increased incidence of cancer among those aged 0-24 years in either period. CONCLUSIONS--During 1963-83 and 1984-90 the incidence of malignant disease, particularly lymphoid leukaemia and non-Hodgkin lymphomas, in young people aged 0-24 in Seascale was higher than would be expected on the basis of either national rates or those for the surrounding areas. Although this increased risk is unlikely to be due to chance, the reasons for it are still unknown. Author-abstract.

JT JPEN. JOURNAL OF PARENTERAL AND ENTERAL NUTRITION.

AB The clinical outcome for 1362 patients with active cancer managed on home parenteral nutrition (HPN) is compared with that of 122 patients with *radiation* enteritis ("cured" cancer) and 416 patients with Crohn's disease. This longitudinal clinical information was reported to the North American Home Parenteral and Enteral Nutrition *Registry* (Oley Foundation/A.S.P.E.N. joint project) between 1985 and 1989. The data shows that the number of active cancer patients on this therapy is increasing 13% per year. The annual survival rate is 25% for patients with active cancer, as compared with 88% for patients with *radiation* enteritis and 95% for patients with Crohn's disease. Although 50% of all active cancer patients starting HPN are dead within 6 to 9 months, the prognosis is somewhat better in children, and 20% of these active cancer patients appear to do well, returning to full oral nutrition and experiencing complete rehabilitation. These are presumed to be patients with a potentially curable cancer requiring super-aggressive treatment, which causes temporary severe

gastrointestinal dysfunction. Adult active cancer patients have the same rehospitalization rate for HPN complications (once per year) as *radiation* enteritis and Crohn's disease patients. However, their rehospitalization rate for non-HPN complications is four times higher. This article reviews the factors that may explain the growth of HPN in active cancer patients and discusses some of the unanswered clinical questions that urgently need to be addressed to more effectively determine the appropriateness or inappropriateness of HPN management in the active cancer setting. Author-abstract.

IN Norwegian Radium Hospital, Oslo.

JT JOURNAL OF CLINICAL ONCOLOGY.

AB PURPOSE: In the period 1968 through 1988, The Norwegian Radium Hospital (NRH) treated an unselected population of 1,152 patients with Hodgkin's disease (HD) that comprised more older patients (mean age, 43 years) than most other institutions. We considered it important to evaluate these patients for development of second cancers (SCs). PATIENTS AND METHODS: The Norwegian Cancer *Registry* identified previously untreated patients with HD treated at NRH who had developed a SC more than 1 year after diagnosis of HD. The relative risk ratio (RR) (observed/expected cases) and the cumulative risk were calculated. RESULTS: Sixty-eight patients had developed a SC, including nine acute nonlymphocytic leukemias (ANLLs), eight non-Hodgkin's lymphomas (NHLs), and 51 solid tumors, including 11 lung cancers. The RR of SC and leukemia was 1.86 (95% confidence interval `CI:, 1.4 to 2.4) and 24.3 (95% CI, 11.1 to 46.2), respectively. The RR of SC was highest in younger patients (< 41 years, RR = 3.8). No significant association between splenectomy and development of ANLL was found. The influence of treatment and follow-up time on the development of SC agrees with data from other large cancer institutions. CONCLUSION: (1) The low RR of developing a SC in this study is probably due to the number of older patients included, who have a lower RR of developing a SC due to less

aggressive treatment, shorter follow-up time, and higher incidence of cancer in the expected background population. (2) The low RR and cumulative risk of developing ANLL may be due to the limited use of extensive chemotherapy (CT) in our hospital in the earlier years. Author-abstract.

JT CHEST.

AB OBJECTIVE: To define the basis for the conflicting reports on the prognosis of lung cancer in young adults. DESIGN: Retrospective review of lung cancer patients between 1977 and 1988. SETTING: Medical centers in Chicago (Northwestern Memorial Hospital), northern Israel (Rambam Medical Center), and northern Italy (S. Anna and U. of Pavia Hospitals). PATIENTS: Patients were ≤ 45 years of age with a diagnosis of primary lung cancer identified from tumor *registry* records, pathology reports, and hospital charts, plus a sample of patients > 45 years of age. MEASUREMENTS AND MAIN RESULTS: In Chicago, younger patients had a higher incidence of chest pain, fever, and neurologic symptoms at presentation than the older patients, and fewer were asymptomatic. They also had more lower lobe lesions on chest roentgenogram, a higher incidence of adenocarcinoma, more advanced disease, an increased likelihood of receiving chemotherapy, and reduced survival ($p < 0.03$). The poorer prognosis was due to more advanced disease at presentation. In Israel, younger patients more frequently presented with stage I disease than the older patients and they had a higher incidence of adenocarcinoma, an increased likelihood of receiving treatment especially surgery, and better survival ($p < 0.02$). There were no differences between the two age groups for symptoms, symptom duration, and chest roentgenogram findings. Compared with the younger patients in Chicago and Israel, those from northern Italy had more squamous cell cancers and fewer adenocarcinomas, more commonly presented with stage I or II disease, received *radiation* therapy less frequently, and were given supportive care more often. Survival was low and comparable to that reported from Chicago. CONCLUSION: Differences exist in the clinical characteristics, pathologic findings, and prognosis of younger and older patients with lung cancer from the same region and

of younger patients from different regions. The difference in prognosis is related in part to the stage of disease at presentation and the ability to undergo resectional surgery. Author-abstract.

JT INTERNATIONAL JOURNAL OF CANCER.
AB It is recognized that survivors of Hodgkin's disease are at a substantially increased risk of lung cancer. A collaborative group of population-based cancer *registries* and major treatment centers carried out a case-control study, in which 98 cases of lung cancer were identified in patients who had survived at least 1 year following a diagnosis of Hodgkin's disease. A total of 259 matched controls were selected from patients with Hodgkin's disease who did not develop subsequent lung cancer, and for both cases and controls detailed information was abstracted from medical records concerning stage and treatment of Hodgkin's disease. Patients treated with chemotherapy alone had about twice the risk of developing lung cancer than those treated by radiotherapy alone or both modalities. There was no increase in risk with cumulative number of cycles of chemotherapy. Among patients treated with radiotherapy alone, there was an increase in risk related to estimated *radiation* dose to the lung. There was also a strong association between cigarette smoking and the risk of lung cancer. The finding of a higher risk following chemotherapy than following radiotherapy was unexpected, but could not be explained by any identified methodological flaws. A plausible

JT CHILDS NERVOUS SYSTEM.

AB The management of tumors of the pineal region differs between Western countries and Japan. This paper reports on a worldwide survey of individual experience and regimens for treating pineal region tumors in different patient populations. Fifteen pediatric neurosurgeons from nine different countries participated in the survey, and a total of 408 pineal region tumors were evaluated. Determination of tumor histology as an initial procedure was strongly supported by the majority of neurosurgeons in North and Central America and Europe (group A), whereas all but one from Asia and Egypt (group B) emphasized initial application of the *radiation* test. The analysis of patient populations clearly revealed racial differences in tumor type which explain this discrepancy. Germinoma, the most radiosensitive tumor, constituted 43-70% (mean: 53.7%) of tumors in group B, followed by teratoma, pineoblastoma, and others, whereas in group A the incidence of germinoma was only 21-44% (mean: 34.7%), followed by a variety of tumors, such as astrocytoma, pineoblastoma, etc. The age distribution among intracranial germ cell tumors (GCT) obtained from data from the Brain Tumor *Registry* in Japan also demonstrated clear differences in the incidence of tumor types in different age groups in Japan: while germinoma constituted 70-84% of GCT in patients between the ages of 15 and 35 years, the incidence was much lower before 15 years and after 35 years, being 24% of tumors under 4 years and 34% of tumors after 40 years of age. The therapeutic regimen for pineal region tumors should depend on the patient population concerned, because of the differences relating to race and age distribution. Author-abstract.

JT HEALTH PHYSICS.

AB Radioactive measurements and histopathologic findings are described in a patient administered Thorotrast, a radiographic contrast agent, 36 y prior to death and compared with cancer risks noted in epidemiologic studies. This person designated as U.S. Uranium *Registry* (USUR) Case 1001: had prearranged for donation of her body to the USUR and the National Cancer Institute for study. Elevated levels of radioactivity were noted in those organs in which excess cancers have been reported in epidemiologic surveys of Thorotrast-exposed subjects. Hepatic tissue in USUR Case 1001 was estimated to have received an average lifetime absorbed dose of 16.2 Gy, based on radiochemical analyses, consistent with the high risks for liver tumors reported in all studied populations. Thorotrast was present throughout the bone marrow of USUR Case 1001, who died

secondary to complications of refractory anemia with excess blasts (RAEB). Elevated risks for acute myeloid leukemia have been noted in Thorotrast patients, and more recently, cases of RAEB and RAEB in transformation have been reported. The thorium decay series includes the bone-seeking radionuclides ^{224}Ra and ^{228}Ra , which have been associated with high risks for osteosarcomas, although the association between Thorotrast and bone cancer is not as convincing. The skeleton of USUR Case 1001, however, contained significant levels of radioactivity. Other tissues evaluated in USUR Case 1001 included

t, Universitaet

Munchen, Germany.

JT BONE MARROW TRANSPLANTATION.

AB Cancer may be serious late effect of marrow transplantation.

Radiation, chemotherapy, immunosuppression and the original disease for which transplantation was performed may predispose to the development of cancer. 116 of 9732 patients reported to the IBMTR (International Bone Marrow Transplant *Registry)* have developed a new malignancy. Late effects were evaluated by the EBMT-EULEP (European Bone Marrow Transplant-European Late Effect Project) Late Effect Study Group in 147 patients surviving 6 years and 79 patients surviving more than 10 years. New malignancies developed in 11 of these patients. Lymphomas and leukemia comprised 73 cases reported to the IBMTR and one case reported to the EBMT-EULEP study. Tumors of the skin, oropharynx, vulva vagina and cervix prevailed in 41 patients with solid tumors. The distribution of malignancies is similar to that observed in organ transplant patients not given *radiation* or chemotherapy and suggests immunosuppression as a major contributory factor. In dogs the incidence of malignancies was studied after either chemotherapy or total body *radiation* in various regimens and marrow transplantation. Both chemotherapy and *radiation* shortened tumor-free survival in comparison to untreated dogs. Higher doses, larger fractions and shorter treatment schedules enhanced earlier tumor development. Soft tissue sarcomas and thyroid carcinoma were most frequent in treated, mammary carcinoma in untreated dogs. In treated dogs deaths from cancer were observed starting at the age of 5 years as compared to untreated dogs at the age of 9 years. The data from animal experiments indicate that the incidence of solid tumors in marrow transplant patients may still rise in the coming decades. Author-abstract.

46

emothotherapy was the predominant treatment. Ninety-nine patients met study criteria, with a median follow-up of 11.4 years (range 0.5 to 41 years). The patient group was compared to patients of all ages, treated at Memorial Sloan-Kettering Cancer Center in 1960 (5 and 10 years) and to patients treated between 1940 and 1943 (30 year follow-up). At the 5, 10, and 30 year follow-up periods, patients in the young age group consistently had disease-specific survival 10-20% lower than their older counterparts. For young patients who survived their first cancer diagnosis, second primaries both in the

contralateral breast and elsewhere, played a significant role in determining their subsequent life span. When compared to risks of second primary cancers in the National Cancer Institute's SEER (Surveillance, Epidemiology and End Results Program) Cancer *Registry* for all ages, the increased risk for very young breast cancer patients was significant ($p = 0.000$). With these two findings in mind, treatment for young patients with breast cancer should focus not on local therapy options alone but on the increased risk of both systemic disease and of second primaries. Author-abstract.

AB OBJECTIVES. Treatment and mortality risk were compared between prostate cancer patients receiving care in fee-for-service settings and those receiving care in a health maintenance organization (HMO). METHODS. Two samples were obtained from a population-based tumor *registry.* Patients in the first sample ($n = 201$) were interviewed shortly after diagnosis to obtain data on income, education, overall health status, and expenditures for health status, and expenditures for health care. These data were combined with information from the tumor *registry* on cancer stage, age, treatment, place of residence, and source of care. Only tumor *registry* data were obtained for most patients in the second sample ($n = 962$). For both samples, survival time was monitored for up to 80 months. RESULTS. Multivariate analysis of data from the interviewed sample indicated that HMO patients were less likely to receive surgery but more likely to receive *radiation* therapy than were those in fee-for-service settings. Mortality risk was lower for the HMO patients than for those in fee-for-service plans. Findings based on the second sample were nearly identical. CONCLUSIONS. This study suggests that HMOs may offer important advantages to lower-income patients at risk for specific life-threatening diseases. Author-abstract.

AB PURPOSE: Although most second malignancies are treatment related, their occurrence also may be due to an underlying systemic disease or chromosomal abnormalities shared by multiple organs in which they are tumorigenic. We attempted to identify unusual tumor pairs that might provide a clue to shared genetic etiologies. PATIENTS AND METHODS: Medical records and tumor *registry* correspondence of 1,743 patients (0 to 18 years at diagnosis) were reviewed. For those said to have a second malignancy, biopsy and autopsy records and slides were reviewed to confirm initial and secondary diagnoses. RESULTS: Two hundred fifty-eight patients had follow-up of at least 10 years and 157 of at least 20 years. Second malignancies were identified in 14 patients. The estimated cumulative incidence of a second cancer was approximately 1% within 10 years. At 20 years after diagnosis, the actuarial estimate was 3%. Although most second cancers were likely treatment related, several tumor pairs could not clearly be explained on that basis, including thyroid carcinoma followed by an ovarian sarcoma, and acute lymphoblastic leukemia associated with renal leiomyosarcoma. Based on one case in this series and a review of the literature, associations between Wilms' tumor, abdominal *radiation,* and adenocarcinoma of the colon and hepatocellular carcinoma are suggested. CONCLUSIONS: We conclude that continued surveillance of very-long-term survivors of childhood cancer, which is usually accomplished by internists, family practitioners, and adult oncOLOGIE.

AB From January 1977 through December 1989, a total of 1,569 patients with pharyngolaryngeal cancer (oropharynx: 240, nasopharynx: 221, hypopharynx: 246, and larynx: 862) were treated at the Department of Radiology, Osaka University Hospital and the Department of *Radiation* Therapy, The Center for Adult Diseases, Osaka. The incidence of other primary cancers in these patients was investigated using the data base of *radiation* therapy combined with information from hospital-based and Osaka prefectural cancer *registries.* One hundred and seventy-six of the 1,569 patients (11%) had other primary cancers (oropharynx: 21%, nasopharynx: 7%, hypopharynx: 13%, and larynx: 9%). The time of development of other primary cancers in more than 50% of the cases ranged between one year before and one year after the diagnosis of primary pharyngolaryngeal cancer. The expected number of the second primary cancer was estimated by multiplying the age-sex specific incidence rates for Osaka residents with person-years at risk based on Osaka prefectural cancer *registry* data. The observed/expected (O/E) ratios were 3.17 (p less than 0.01) for oropharyngeal, 2.01 (p less than 0.01) for nasopharyngeal, 2.16 (p less than 0.01) for hypopharyngeal and 1.10 (n.s.) for laryngeal

cancer. The most common sites of the second primary cancer in order of frequency were: the oral cavity and pharynx, esophagus and lung for oropharyngeal cancer, the oral cavity and pharynx for nasopharyngeal cancer, the oral cavity and pharynx and the esophagus for hypopharyngeal cancer and the oral cavity and pharynx, esophagus and lung for laryngeal cancer. JT CANCER.

AB From 1967 to 1990, 96 previously untreated patients with cervicovaginal cancer associated with a history of vaginal pessary use to control uterovaginal prolapse were referred to eight *radiation* therapy departments in France. Sixty-eight patients had cervical cancer, and 28 had vaginal cancer. The mean interval between pessary insertion and cancer diagnosis was 18 years, with a range of 1 to 41 years. Most patients received *radiation* therapy and brachytherapy. Few (5%) had Grade 3 treatment side effects. The overall 5-year relative survival rate was 54%; nonsurvival was related to locoregional recurrence. Because almost all tumors occurred at the site of pessary insertion, foreign body chronic inflammation in association with viral infection may be the cause of the tumors. Author-abstract.

JT ARCHIVES OF ENVIRONMENTAL HEALTH.

AB Cancer mortality risks for individuals who were employed at nuclear facilities in Tarapur and for their respective family members with whom they lived were examined. Cancer deaths that occurred in this population between 1971 and 1988 were compared with death rates published by the Bombay City Cancer *Registry.* Risks were expressed as standardized mortality ratios (SMRs), which were computed by dividing the observed number of deaths by the expected number of deaths and multiplying this value times 100. There were 11 deaths from cancer among the employees, and this figure was too small to permit any trend analysis with respect to *radiation* exposures. The SMRs for all cancers and leukemia for male employees and for middle-aged male family members who were not exposed to any *raure* occurred in 25%, surface excrescences in 40%, and adhesions in 46%. None of these factors had a significant effect on recurrence rate or survival. Eleven patients received adjuvant *radiation* therapy (10 abdomino-pelvic and 1 pelvic alone), four adjuvant chemotherapy, and one both *radiation* therapy and chemotherapy. The rest (65) received no adjuvant therapy. Due to the small numbers and infrequent events, it was not possible to analyze and thus draw valid conclusions

regarding the effect of adjuvant therapy on survival or recurrence. The overall survival (OS) and cause specific survival (CSS) were 85% and 96% at 10 years, respectively. No Stage I patient died of tumor. OS for Stage I patients was 90% at 10 years, the majority of whom (61 of 63) received no adjuvant therapy, and is thus unnecessary in Stage I disease. The adequacy of unilateral oophorectomy or ovarian cystectomy could not be confirmed because of small numbers. The 10 year OS and disease-free survival in Stage II and III were 75% and 50%, respectively, despite the use of adjuvant *radiation* therapy, chemotherapy, or both. It is necessary to create a multi-center tumor *registry* in order to acquire a prospective data base from which to develop sound therapeutic decisions. Author-abstract.

JT INTERNATIONAL JOURNAL OF CANCER.
AB Cancer mortality was studied in 10,552 Swedish hyperthyroid patients treated with ¹³¹I between 1950 and 1975. The patients were matched with the Swedish Cause-of-Death Register and the cases of 977 patients to have received more treatment. There also was a trend ($P = 0.12$) for Hispanic patients to have a more advanced stage of cancer. Hispanic patients lost significantly more weight (P less than 0.001) and had significantly lower serum albumin levels (P less than 0.0001). According to the results of multivariate survival analyses, the variables that were predictive of a poor prognosis included advanced stage of disease, decreased serum albumin levels, increased weight loss, administration of chemotherapy, lack of *radiation* therapy or surgery, and advanced age. Ethnicity was not a significant predictor of survival either in univariate analyses, or within patients with the same stage of disease, or after adjustment for other prognostic factors. In conclusion, the natural history of squamous cell carcinoma of the head and neck is the same for Hispanic and Anglo-American patients. Author-abstract.

AB Retrospective studies were made of patients with orbital rhabdomyosarcoma (RMS) who were registered in the Japan Children's Cancer *Registry* and the National *Registry* of Ocular Tumors in Japan during 1974-1989. Thirty-five children under 15 years of age were registered as orbital RMS patients. The median age of onset was 5 years and 2 months; lid swelling was the most frequent initial symptom and finding. Histologically, 79% were classified as the

embryonal type. Orbital exenteration was the standard treatment until the mid-1970's, but all the 5 patients who had only surgical therapy experienced relapses. Since the mid-1970's, a combined regimen of surgery, *radiation* and chemotherapy has been used. Chemotherapy has recently been considered to play the most important role in this combined therapy. Among the 35 patients studied, three patients with only biopsy as the surgical procedure have had no relapses up to the present time. Recurrent tumors developed in 15 of the remaining 32 patients: 7 of those were local, 8 were distant. All relapses (10 of the 14 patients in the 1970's, and 5 of the 18 in the 1980's) occurred within 1 year and 11 months after initial treatment. The 3-year survival rate of these 32 patients, estimated by the Kaplan-Meier method, was 70% (52% in the 1970's, 86% in the 1980's). Author-abstract.

JT JOURNAL OF *RADIATION* RESEARCH.

AB A tumor *registry* is essential in the systematic collection and analysis of tumor data in a defined population. Population-based tumor *registries* have been in operation for more than 30 years in Hiroshima and Nagasaki. While the tumor *registry* data have previously been used for many site-specific cancer studies in atomic bomb survivors, overall analysis of tumor *registry* based cancer incidence data among the atomic bomb survivors has not been undertaken for some time. However, a recent improvement in the tumor *registries* has made it possible to analyze most recent cancer incidence data among the Life Span Study population. Preliminary analysis under way indicates a potential power of the data. There are a few methodological problems associated with the use of the incidence data, especially relating to consistency of data and migration. Several measures taken to resolve such problems are discussed. Author-abstract.

71

AU Boice-J-D Jr. Mandel-J-S. Doody-M-M. actors with attained age. It is interesting that 10% of all technologists allowed others to practice taking radiographs on them during their training. Nearly 4% of the respondents reported having some type of cancer, mainly of the skin (1517), breast (665), and cervix (726). Prospective surveys will monitor cancer mortality rates through use of the National Death Index and cancer incidence through periodic mailings of questionnaires. This is the only occupational study of *radiation* employees who are primarily women and should provide new information on the possible risks associated with relatively low levels of exposure. JT INTERNATIONAL JOURNAL OF EPIDEMIOLOGY.

AB Beginning in 1985, a sudden and sustained doubling of salivary gland cancer incidence, among men only, is observed in the San Francisco-Oakland Metropolitan Statistical Area. *Registry* data are examined to determine the nature of this increase and its possible association with the AIDS epidemic. Changes in patient characteristics are assessed by comparing their distribution among recently diagnosed cases (1985-1988) to an expectation based on population growth and the age-specific incidence among patients diagnosed earlier (1973-1984). Based on the observed patterns, it is unlikely that the temporal increase in these tumours is a direct result of the AIDS epidemic or solely the result of a shift in the prevalence of established risk factors. The increase is predominantly seen in men over the age of 75 at diagnosis ($O/E = 2.3$, $p = 0.02$) and is observed among both those with and without a prior cancer ($O/E = 2.7$, $p = 0.02$ and $O/E = 1.5$, $p = 0.06$, respectively). *Radiation* for the prior cancer was not associated with increased occurrence. Military exposure is crudely approximated by examining birth cohorts. However, the cohort data do not support a hypothesis

of military exposure. Author-abstract.

JT MUTAGENESIS.

AB The genetic consequences of radioactive fall-out deposition from the Chernobyl (USSR) accident in Hungary was evaluated as a part of the ongoing programme on the population-based Hungarian Surveillance of Germinal Mutations. The surveillance is based on three groups of indicator conditions: 15 sentinel anomalies (indicators of germinal dominant gene mutations), Down's syndrome (an indicator of germinal numerical and structural chromosomal mutations) and unidentified multiple congenital abnormalities (indicators of germinal dominant gene and chromosomal mutations). Cases with these indicator conditions were selected from the material of the Hungarian Congenital Abnormality *Registry.* After the diagnostic accuracies were checked, familial and sporadic cases were separated. Only the latter group was evaluated for evidence of new mutations. The analysis did not reveal any measurable germinal mutagenic effects of the Chernobyl accident. Furthermore, there were no significant differences in the rates of these three groups of indicator conditions between regions with higher and lower increased background *radiation.* Author-abstract.

JT JOURNAL OF THE NATIONAL CANCER INSTITUTE.
AB The incidence of new primary cancers was evaluated in 3538 postmenopausal patients who had received surgical treatment for primary breast cancer. Of these patients, 1828 with a low risk of recurrence received no further treatment. High-risk patients were randomly assigned to one of two groups. The first group (n = 846) received postoperative radiotherapy, while the second group (n = 864) received radiotherapy plus tamoxifen at a dose of 30 mg given daily for 48 weeks. The median observation time was 7.9 years. In comparison with the number of new cancers in the general population, the number of new cancers in the three groups was elevated mostly due to a high number of cancers of the contralateral breast and of colorectal cancers in the high-risk groups. The cumulative risk of nonlymphatic leukemia was increased among patients who received postoperative radiotherapy (P = .04). Cancer incidence in the high-risk tamoxifen-treated group relative to that in the high-risk group not treated with tamoxifen was not significant (1.3). No protective effect of tamoxifen on the opposite breast was seen (rate ratio for breast cancer = 1.1), but a tendency to an elevated risk of endometrial cancer was observed (rate ratio = 3.3; 95% confidence

interval = 0.6-32.4). Continued and careful follow-up of women treated with tamoxifen is necessary to clarify the potential cancer-suppressive or cancer-promoting effects of this drug.

AB Between 1954 and 1983, 7620 patients were treated for breast carcinoma at Institut Gustave Roussy (France). Of these patients, 6919 were followed for at least 1 year. Out of these, 11 presented with sarcomas thought to be induced by irradiation, 2 of which were Steward-Treves Syndrome, and 9 of which were sarcomas within the irradiated fields. All histological slides were reviewed and a comparison with those of breast cancer was done. The sites of these skin tumors. Malignant melanoma, however, was not significantly elevated. Overall, 80 neoplasms were identified from an extensive search of the pathology logs of all major hospitals in Israel and computer linkage with the national cancer *registry.* *Radiation* dose to the scalp was computed for over 10,000 persons irradiated for ringworm (mean 7 Gy), and incidence rates were contrasted with those observed in 16,000 matched comparison subjects. The relative risk of radiogenic skin cancer did not differ significantly between men or women or by time since exposure; however, risk was greatest following exposures in early childhood. After adjusting for sex, ethnic origin, and attained age, the estimated excess relative risk was 0.7 per Gy and the average excess risk over the current follow-up was 0.31/10(4) PY-Gy. The risk per Gy of *radiation-induced* skin cancer was intermediate between the high risk found among whites and no risk found among blacks in a similar study conducted in New York City (Shore et al., Radiat. Res. 100, 192-204, 1984). This finding suggests the role that subsequent exposure to uv *radiation* likely plays in the expression of a potential *radiation-induced* skin malignancy. JT ENVIRONMENTAL HEALTH PERSPECTIVES.

AB In this paper we combine Japanese data on *radiation* exposure and cancer mortality with U.S. data on cancer incidence and lethality to estimate the effects of ionizing *radiation* on cancer incidence. The analysis is based on the mathematical relationship between the mortality rate and the incidence and lethality rates, as well as on statistical models that relate Japanese incidence rates to U.S. incidence rates and *radiation* risk factors. Our approach assumes that the risk of death from causes other than the cancer does not depend on whether or not the cancer is present, and among individuals

with the cancer, the risk of death attributable to the cancer is the same in Japan and the U.S. and is not affected by *radiation* exposure. In particular, we focus on the incidence of breast cancer in Japanese women and how this incidence is affected by *radiation* risk factors. The analysis uses Japanese exposure and mortality data from the *Radiation* Effects Research Foundation study of atomic bomb survivors and U.S. incidence and lethality data from the Surveillance, Epidemiology, and End Results *Registry.* Even without Japanese incidence data, we obtain reasonable estimates of the incidence of breast cancer in unexposed Japanese women and identify the *radiation* risk factors that affect this incidence. Our analysis demonstrates that the age at exposure is an important risk factor, but that the incidence of breast cancer is not affected by the city of residence (Nagasaki versus Hiroshima) or the time since exposure. AB External gamma-ray exposures from fallout originating at the Nevada Test Site (NTS) have been assigned to 6,507 individual subjects (1,177 leukemia cases and 5,330 control subjects) who died as Utah residents between 1952 and 1981. Leukemia cases were identified, confirmed, and classified by cell type from the Utah Cancer *Registry,* Utah State vital records, and medical records. Residential histories were obtained from the Deceased Membership File (DMF) of the Church of Jesus Christ of Latter-day Saints (LDS), supplemented by information from the LDS Church Census Records that were taken in 1950, 1955, and 1960-62. Control subjects were selected randomly within age strata from the DMF and were frequency-matched to the cases by age at death and for sex. Individual *radiation* exposures were assigned as a function of residence location and time interval for each residence during the fallout period (1951-1958) using geographic exposure data taken from the literature. Temporal distribution of exposure for subjects who resided in more than one locality or who were born or died during the fallout period was determined from data of other investigators. Calculated gamma-ray exposures for each place of residence were summed for each subject to yield the exposure to fallout from the NTS. Author-abstract.

JT DEVELOPMENTS IN BIOLOGICAL STANDARDIZATION.

AB Immunoscintigraphy is a new method for in vivo diagnosis of diseases using monoclonal antibodies. Emphasis is placed on diagnosis of malignant tumors although the range of application includes a number of non-malignant diseases. To date, no European country has issued clear guidelines on the testing and registration of those monoclonal antibodies labelled with a radionuclide and used for diagnostic. This involves the risk of overregulation which would considerably reduce the applicability of the method. This holds particularly true since the complications initially anticipated with the use of such compounds did not occur. The conduct of immunoscintigraphy has evolved linked to the Swedish Cancer Register (1958-1983) and the Swedish Cause-of-Death Register (1952-1983). Ninety-five cases of childhood cancer before the age of 16 were identified. Two controls from the Twin Register were matched to each case by sex and year of birth. Maternal X-rays during pregnancy were documented for 41% of the cases and 36% of the controls. The crude relative risk of any childhood cancer associated with any prenatal X-ray was 1.2 (95% CI; 0.7-2.1). For the cases 64% of the X-rayed women had had abdominal X-rays, the numbers for the controls were 57%. Fifty-nine per cent of the X-rayed women had had abdominal X-rays, which were associated with a relative risk for all cancers of 1.4 (CI; 0.8-2.5), leukemias 1.7 (CI; 0.7-4.1) and tumors of the central nervous system 1.5 (CI; 0.5-4.2). There was no apparent confounding by mother's age, drug use, obstetric complications, previous miscarriages, social class or length of pregnancy. The observed relative risks of cancer following prenatal X-ray exposure are consistent with previous studies, suggesting that the developing fetus may be more sensitive to the carcinogenic effects of ionizing *radiation* than are children irradiated post-natally. JT BRITISH JOURNAL OF CANCER.

AB To examine the hypothesis that radiotherapy for breast cancer can cause myocardial infarction, cause-specific mortality by laterality of the primary tumour was analysed among 54,617 breast cancer patients reported to the Swedish Cancer *Registry* during 1970-1985. The rationale was that radiotherapy for a left-sided breast cancer invariably results in higher doses of *radiation* to the myocardium than a similar treatment given for a right-sided tumour whereas other possible risk factors for cardiovascular disease probably are unrelated to the laterality of the tumour. The median follow-up was 9 years (range 1-17 years). Patients with left-sided tumours were found to have a higher mortality due to myocardial infarction than patients with right-sided tumours (P less than 0.01) but there was no difference in regard to total intercurrent mortality. Further analyses of individual radiotherapy studies are warranted to quantify the excess risk associated with *radiation* and to study the significance of the type of *radiation,* portal arrangements, total dose and fractionation. It seems reasonable to assume that adverse effects of *radiation* are dose-related and may thus be minimised or prevented by the use of appropriate treatment techniques. Author-abstract.

AB There are epidemiologic similarities between salivary and skin neoplasms that could be attributed to exposure to ultraviolet *radiation.* To explore further the etiologic parallels between these two types of cancer, we studied the multiple primary association between salivary gland cancer with that of other cancers known to be induced by ultraviolet light exposure, using data from the SEER program for 1973-1984. Because nonmelanoma skin cancers other than cancers of the lip are not routinely reported to the SEER *registries,* we specifically evaluated the associations with melanoma and lip cancers. Expected numbers of subsequent primaries (melanoma and lip) for the 904 white men and 784 white women with an initial salivary gland cancer were computed from incidence rates using the Connecticut Tumor *Registry.* There were significantly increased risks for subsequent lip cancer among men (RR = 8.7) and for melanoma among women (RR = 7.1). Among men there was also a significant association between an initial lip cancer and risk of subsequent salivary gland cancer (RR = 12.7). These observations, together with reported increases in incidence of these tumors, suggest a common etiology, which could partly be explained because of exposure to ultraviolet *radiation.* Author-abstract.

AB Uterine sarcomas are uncommon malignancies. We retrospectively examined 24 cases of "high grade" endometrial stromal sarcomas (ESS). The histologic diagnosis was made if there was a high grade sarcoma with a high mitotic index and nuclear anaplasia. Heterologous elements could be present, if focal only. Leiomyosarcomas, mixed mesodermal sarcomas, and carcinosarcomas were excluded. Mitotic index was expressed as the number of mitoses per 10 high-power fields in active areas. Tumor grade was based on nuclear anaplasia. ESS were 5.7% of all uterine sarcomas. Median age was 58.2 years; median duration of symptoms was 67.5 days. Abnormal bleeding was the presenting complaint in 91.7%. Uterine enlargement was seen in 33%; protrusion through the cervical os was seen in 9 cases. Total abdominal hysterectomy and bilateral salpingo-oophorectomy was performed in 95.8%. Twenty patients had myometrial involvement; 5 patients had serosal spread and extrauterine disease; residual disease was seen in 3 patients. Adjuvant *radiation* was not beneficial. Ten patients had recurrences: 60% in the pelvis, 50% each with subcomponent of abdominal or distant disease. Overall survival was 3.4 years and was significantly associated with extent of disease, size of the primary tumor, and grade. Author-abstract.

AB The development of second malignant tumors (SMTs), in patients who have had their first tumor treated successfully, represents a serious limitation of current therapeutic strategies for head and neck cancers. To improve our understanding of the current magnitude of the problem and the various factors that might influence its

importance, we reviewed the *Radiation* Therapy Oncology Group's (RTOG) prospectively collected *registry* of all head and neck patients seen in participating member institutions between February 1977 and April 1980. A total of 928 patients were identified who had squamous cell carcinomas of the head and neck region, no prior or coincident history of another malignant tumor, and whose planned treatment consisted of *radiation* therapy only. A total of 110 second, independent, malignant tumors occurred in these patients. Overall, the estimated risk of developing a second tumor within 3 years of radiotherapy was 10%, within 5 years 15%, and within 8 years 23%. Minor differences in frequency were observed for different primary

- s. Thus, an ozone depletion of 1% will result in an increase in the incidence of BCCs by 1.6-2.1% and of SCCs by 1.3-1.7%. There were no significant differences between the values for men and women. Neither was there any significant difference between Ab values found for skin commonly exposed to sunlight (face) and for skin sites normally covered by clothes and therefore receiving much lower exposures, in spite of the fact that the tumor density per unit skin area was a factor of 20 or more larger at the former sites. This observation, as well as the curves relating cancer incidence with annual exposure to carcinogenic sunlight, supports a power law relationship between cancer incidence and annual sun exposure. Sunlight appears to be the main cause of BCCs and SCCs even at the high latitudes of Northern Norway. All over, BCCs were found to be about 6 times more frequent than SCCs. The ratio of the incidence of BCCs to that of SCCs seemed to be independent of the latitude. Finally, BCCs were found to be equally frequent among men and women, while SCCs were found to be about twice as frequent among men as among women. Author-abstract.

AB Small-cell carcinoma of the lung has been shown to be quite responsive to chemotherapy. Unfortunately, these responses are often short in duration, and long-term, disease-free survival is infrequent. This review of tumor *registry* records of all patients with small-cell carcinoma of the lung treated at Charleston Area Medical Center (CAMC) from 1962 to 1983 showed that 21 of 500 (four per cent) survived 30 months or longer. Eighteen patients had limited-extent disease. Although the majority of patients received chemotherapy alone or chemotherapy and *radiation,* there were survivors in all treatment groups (i.e. surgery alone or radiotherapy alone). Six of the 21 long-term survivors eventually had relapses occurring as late as 88 months after diagnosis. The overall poor survival of patients with small-cell lung cancer suggests a need for the development of novel initial approaches to therapy. Author-abstract.

AB Each year, tens of thousands of persons are diagnosed with cancer, are treated, and become survivors while still in their reproductive years. Their concerns about possible germ-cell damage as a result of life-saving *radiation,* chemotherapy, or both are plausible, based on evidence from animal models and from somatic cell mutations in human beings. A 40-year follow-up of survivors of the atomic bomb blasts in Japan showed no detectable genetic damage and suggested that the human gonad is more resistant to radiogenic mutation than the laboratory mouse. The pooled results of studying 12 series of offspring of cancer patients showed a 4% rate of major birth defects (similar to that of the general population) and an excess of fetal loss and low birth weight in offspring of women who received abdominal radiotherapy. According to preliminary evaluation of a new National Cancer Institute collaboration with five cancer *registries,* offspring of survivors of childhood cancers had no more birth defects than expected and, beyond an increase in probably familial cancers in children younger than 5, no overall increase in childhood cancer. Ideally, genetic and reproductive counseling should take place as soon as cancer is diagnosed (before therapy starts) and again when pregnancy is contemplated. Author-abstract. 28 Refs.

transmission of light of different wavelengths might serve as an important discriminating variable. If solar UV *radiation* is implicated in the development of melanoma, then altitude should emerge as a significant factor in epidemiologic studies. If visible

or IR *radiation* is the active agent, then differences on the basis of altitude should be small or negligible. Intrinsic solar variations that follow the annual sunspot number appear inadequate in either the UV or the visible band to account directly for the apparent 11-year modulation of melanoma incidence found in some *registries.* Secondary atmospheric effects brought about by the action of solar UV changes on the ozone layer may be adequate to explain a weak 11-year modulation in melanoma incidence, although continuous measurements of UV-B flux made at sites in the United States through a full solar cycle have shown no such effect. Nor do these early measurements reveal the long-term increase in UV-B intensity expected from the destruction of stratospheric ozone by industrial pollutants over the last 10 years. Author-abstract.

AB To evaluate further the relationship between high-dose radiotherapy and leukemia incidence, a nested case-control study was conducted in a cohort of 22,753 women who were 18-month survivors of invasive breast cancer diagnosed from 1935 to 1972. Women treated for breast cancer after 1973 were excluded to minimize the possible confounding influence of treatment with chemotherapeutic agents. The cases had histologically confirmed leukemia reported to the Connecticut Tumor *Registry* (CTR) between 1935 and 1984. A total of 48 cases of leukemia following breast cancer were included in the study. Two controls were individually matched to each leukemia case on the basis of age, calendar year when diagnosed with breast cancer, and survival time. Leukemia diagnoses were verified by one hematologist. *Radiation* dose to active bone marrow was estimated by medical physicists on the basis of the original radiotherapy records of study subjects. Local *radiation* doses to each of the 16 bone marrow components for each patient were reconstructed; the dose averaged over the entire body was 530 rad (5.3 Gy). Based on this dosage and assuming a linear relationship between dose and affect, a relative risk (RR) in excess of 10 would have been expected. However, there was little evidence that radiotherapy increased the overall risk of leukemia (RR = 1.16; 90% confidence interval `CI:, 0.6 to 2.1). The risk of chronic lymphocytic leukemia, one of the few malignancies without evidence for an association with ionizing *radiation,* was not significantly increased (RR = 1.8; n = 10); nor was the risk for all other forms of leukemia (RR = 1.0; n = 38). There was no indication that risk varied over categories of *radiation* dose. These data exclude an association between leukemia and radiotherapy for breast cancer of 2.2-fold with 90% confidence, and provide further evidence that cell death predominates over cell transformation when high *radiation* doses are delivered to limited volumes of tissue. Author-abstract.

JT CANCER.
AB A case-control study was conducted to assess the risk factors associated with the development of a contralateral primary breast cancer among women who had had a first primary breast cancer. Hospital records were reviewed for 292 women with an incident contralateral breast cancer, diagnosed in one of eight hospitals between July 1, 1975 and December 31, 1983, and for a comparison group of 264 surviving unilateral breast cancer patients, previously diagnosed in the same hospitals. All subjects were identified through the records of the Connecticut Tumor *Registry.* Having an initial tumor containing lobular carcinoma was associated with an almost twofold increased risk of developing a contralateral cancer

(aOR = 1.8; 95% CI: 1.0-3.5). Among those for whom a progesterone receptor assay was available, a positive assay was associated with an increased risk of a contralateral primary (aOR = 3.2; 95% CI: 1.0-9.5). AB blood type was also associated with an elevated risk, but this elevation was not statistically significant (aOR = 2.3; 95% CI: 0.7-7.7). Having received *radiation* treatment was not significantly associated with the risk of a contralateral primary (aOR = 0.9; 95% CI: 0.6-1.4), whereas chemotherapy treatment was associated with a significantly lowered risk (aOR = 0.3; 95% CI: 0.1-0.7). The association with chemotherapy appeared to be modified by body build (ROR = 1.5; 95% CI: 1.0-2.3 for a 2.5-unit differential in Quetelet's index). Author-abstract.

AB Recent research has suggested that nonionizing *radiation* in the form of power-frequency magnetic fields may play some role in carcinogenesis in general and in acute nonlymphocytic leukemia in particular. Much of the epidemiologic evidence is preliminary in nature and the methods of previous studies have been criticized. In order to further evaluate this hypothesis, a population-based case-control study of adult acute nonlymphocytic leukemia and residential exposure to power-frequency magnetic fields was carried out in western Washington state. Analyses were based on 114 cases who were newly diagnosed from 1981 to 1984 and identified from a population-based cancer *registry,* and 133 controls who were chosen from the study area by random digit dialing. Magnetic field exposure was estimated from external electrical wiring configurations within 140 ft (42.7 m) of each subject's residence. In addition, magnetic fields were measured inside the subject's residence at the time of interview. Neither the directly measured magnetic fields nor the surrogate values based on the wiring configurations were associated with acute nonlymphocytic leukemia. Author-abstract.

JT CANCER.

AB Using data from the population-based Danish Cancer *Registry,* the

relative risk (RR) of second primary cancer was assessed among 24,970 women with invasive cervical cancer (1943-1982) and 19,470 women with carcinoma in situ of the cervix. The analysis was stratified according to treatment with (+) and without (-) *radiation.* For all second primaries combined, a RR+ = 1.1 (95% confidence interval (CI) = 1.06-1.18) and a RR- = 1.3 (95% CI = 1.13-1.40) was observed after invasive cervical cancers and a RR+ = 3.5 (95% CI = 1.4-7.2) and RR- = 1.1 (95% CI = 0.7-1.6) following in situ cancer. The small overall excess of second primary cancer is accounted for by an increase of some cancers such as lung, bladder, and a concurrent decrease in others such as breast. Although not statistically different from nonirradiated, the RR increased with time since treatment among irradiated invasive cervical cancer patients in organs close to and at intermediate distance from the cervix, reaching a maximum after 30 or more years of follow-up (RR = 1.9; 95% CI = 1.4-2.5). Altogether, for these sites an excess of 64 cases per 10,000 women per year were attributable to *radiation* among survivors of 30+ years. The highest risks among long-term survivors were observed for the following: other genital organs (RR = 5.8; 95% CI = 1.8-13.0) bladder (RR = 5.5; 95% CI = 2.8-9.5), connective tissue (RR = 3.3; 95% CI = 0.4-12.0), stomach (RR = 2.5; 95% CI = 1.1-4.7) and rectum (RR = 2.4; 95% CI = 1.1-4.6). A significant deficit of risk for breast cancer (RR = 0.7, 95% CI = 0.6-0.8) was observed for 10+ years, may be attributable to the effect of ovarian ablation by radiotherapy. It is speculated that the same effect also may explain the observed deficits of brain tumors (RR = 0.6; 95% CI = 0.4-1.0) and skin melanomas (RR = 0.6; 95% CI = 0.3-1.0). It is concluded that cancers attributable to *radiation,* apart from acute nonlymphocytic leukemias, tend to appear late (10 or more years after radiotherapy), and that the risk remains elevated for more than 30 years. Author-abstract.

JT ACTA ONCOLOGICA.

AB The complete material of male breast cancer, 166 cases, reported to the Swedish Cancer *Registry* in 1958-1967 is described and analyzed concerning different prognostic parameters, treatment methods and survival. Age at diagnosis, axillary lymph node status and tumour size all had significant prognostic importance in a multivariate analysis with axillary lymph node status as the strongest factor. Histologic malignancy grade was strongly correlated to axillary lymph node status and tumour size and thus to prognosis, but did not seem to be an independent prognostic factor. The primary treatment methods were quite heterogeneous and were obviously influenced by both age of the patient and clinical tumour status. No significant correlation was found between type of primary treatment and survival, but due to the retrospective nature of the study no definite conclusion could be drawn. Radical mastectomy seemed, however, to

give fewer loco-regional recurrences than both modified radical mastectomy and simple mastectomy. Very few patients in the present series had received *radiation* therapy in adequate doses. The material gave some indications that orchiectomy might prolong survival in patients with recurrent or generalized disease. Author-abstract. 72 Refs.

JT JOURNAL OF THE NATIONAL CANCER INSTITUTE.

AB To quantify the risk of *radiation-induced* leukemia and provide further information on the nature of the relationship between dose and response, a case-control study was undertaken in a cohort of over 150,000 women with invasive cancer of the uterine cervix. The cases either were reported to one of 17 population-based cancer *registries* or were treated in any of 16 oncologic clinics in Canada, Europe, and the United States. Four controls were individually matched to each of 195 cases of leukemia on the basis of age and calendar year when diagnosed with cervical cancer and survival time. Leukemia diagnoses were verified by one hematologist. *Radiation* dose to active bone marrow was estimated by medical physicists on the basis of the original radiotherapy records of study subjects. The risk of chronic lymphocytic leukemia, one of the few malignancies without evidence for an association with ionizing *radiation,* was not increased (relative risk (RR) = 1.03; n = 52). However, for all other forms of leukemia taken together (n = 143), a twofold risk was evident (RR = 2.0; 90% confidence interval = 1.0-4.2). Risk increased with increasing *radiation* dose until average doses of about 400 rad (4 Gy) were reached and then decreased at higher doses. This pattern is consistent with experimental data for which the down-turn in risk at high doses has been interpreted as due to killing of potentially leukemic cells. The dose-response information was modeled with various RR functions, accounting for the nonhomogeneous distribution of *radiation* dose during radiotherapy. The local *radiation* doses to each of 14 bone marrow compartments for each patient were incorporated in the models, and the corresponding risks were summed. A good fit to the observed data was obtained with a linear-exponential function, which included a positive linear induction term and a negative exponential term. The estimate of the excess RR per rad was 0.9%, and the estimated RR at 100 rad (1 Gy) was 1.7. The model proposed in this study of risk proportional to mass exposed and of risk to an individual given by the sum of incremental risks to anatomic sites appears to be applicable to a wide range of dose distributions. Furthermore, the pattern of leukemia incidence associated with different levels of *radiation* dose is consistent with a model postulating increasing risk with

increasing exposure, modified at high doses by increased frequency of cell death, which reduces risk. Author-abstract.

IN Department of Epidemiology and Mass Examination for Stomach Cancer, Center for Adult Diseases, Osaka, Japan.

JT JAPANESE JOURNAL OF CLINICAL ONCOLOGY.

AB Using the data accumulated in the Osaka Cancer *Registry,* a cohort study was conducted on the occurrence of second primary cancers following the first breast cancer in females. Of the 9,503 breast cancer patients newly diagnosed in the period 1965-1982 who were followed up until the end of 1983 (average follow-up period, 5.7 years), 344 developed second cancers, whereas the expected number had been 211 (relative risk (RR) = 1.6; 95% confidence interval (CI) = 1.5-1.8). The increased risk was observed throughout the observation period, and was higher in patients of less than 45 years of age at diagnosis than in older women. Significant excess risks were found for second cancers of the opposite breast (RR = 4.2; 95% CI = 3.4-5.2), buccal cavity (RR = 3.6; 95% CI = 1.6-7.2), stomach (RR = 1.4; 95% CI = 1.2-1.8), colon (RR = 1.8; 95% CI = 1.1-2.1) and thyroid gland (RR = 3.2; 95% CI = 1.5-6.1). The effects of chemo- and radiotherapy administered for initial breast cancer on the increased risk of the above mentioned second cancers were also examined. These therapeutic measures were found not likely to be related to the excess risks for cancers of the buccal cavity, stomach and colon. For second cancer of the opposite breast, however, both chemotherapy and radiotherapy remained as possible risk factors. The effect of *radiation* was proposed as being a likely explanation for the excess risk of second thyroid cancer. Author-abstract.

AB To examine further the epidemiology of contralateral primary breast cancer, a case-control analysis, utilizing information available from the Connecticut Tumor *Registry,* was conducted. Recent cases of

second primary breast cancer were compared to control women who had survived a first breast cancer but had not developed a second. Three hundred and thirty eight incident cases of contralateral breast cancer diagnosed between 1979 and 1982 were identified and compared with an equal number of randomly selected controls and 336 controls frequency matched to the cases on the basis of age at initial cancer diagnosis and the calendar time elapsing since that diagnosis. Risk of

 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB Gardner et al. (Br Med J 1990; 300: 423-429) reported a high
 relative risk for childhood leukemia among children, aged 0-24 years
 at time of diagnosis, born to fathers employed at the Sellafield
 nuclear plant in the U.K. As a result we looked for spatial and
 temporal trends of childhood and young adult leukemia in the Negev,
 where a nuclear plant has been in operation since 1960. We divided
 the Negev into an Eastern part where plant employees are likely to
 live, and a Western part where this is quite unlikely. Reported
 leukemia cases were provided by the Israel Cancer *Registry* for the
 age group 0-24, and for the period 1960-1985. We checked this file
 against data obtained from the hospitals in the area. We added 6
 more cases in the Eastern Negev, none in the Western Negev, and none
 of the reported cases was discarded. There was a total of 192 cases,
 of which 52% were acute lymphatic leukemia. Jewish and Bedouin
 children were studied separately. Among Jewish children the average
 annual incidence rate for the Eastern Negev was 2.76/100,000, the
 Western Negev 3.51. Over time the leukemia rates were consistently
 higher in the Western Negev among children aged 0-9 years, which
 holds especially for acute lymphatic leukemia. There was a sudden
 increase among girls born during the period 1970-1979 in the northern
 part of the Western Negev, which was not noticed among boys. No
 excess cases were found in the small towns around the plant.

 AB There is growing concern about the oncogenic potential of growth
 hormone (GH) used therapeutically. In rat experiments, a variety of
 malignant tumours have been induced following administration of
 supraphysiological doses of GH, whilst in other studies in
 hypophysectomized animals a lower than normal incidence of
 carcinogen-induced neoplasms was reported. In acromegaly, in which
 there is a pathologically sustained high GH level, there is a
 significantly increased incidence of cancer in general and
 specifically of colonic neoplasia. To determine whether the use of
 GH in the treatment of *radiation-induced* GH deficiency causes tumour
 recurrence, a comparison was made of tumour recurrence rates between
 47 children treated with GH for *radiation-induced* GH deficiency after
 treatment for a brain tumour and a control population from the North
 West Children's Cancer *Registry* who did not receive GH (n = 160).
 All cases of acute lymphoblastic leukaemia (ALL), including those
 that were (n = 15) and were not (n = 146) treated with GH were
 reviewed. The computerized tomography (CT) scans in the children
 with brain tumours were reviewed at the time of GH commencement and
 subsequently. There were 5 brain tumour recurrences after GH
 therapy: 1 astrocytoma, 2 ependymomas and 2 medulloblastomas.
 Adjusting for variables other than GH which might affect tumour
 recurrence, the estimated relative risk of tumour recurrence was 0.82
 (95% confidence interval: 0.28-2.37). In each tumour category there
 was no association between the use of GH and subsequent tumour
 recurrence.(ABSTRACT TRUNCATED AT 250 WORDS). Author-abstract.

JT AMERICAN JOURNAL OF CLINICAL ONCOLOGY.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB The most important predictors of long-term survival in patients with
adenocarcinoma of the prostate are histological grade and stage of
disease. However, the role of other epidemiological factors,
particularly age and race, remains controversial. There is a school
of thought that black patients and younger patients have a
biologically more aggressive disease. We analyzed the survival of
914 patients (867 whites and 47 blacks) with localized adenocarcinoma
of the prostate treated with external beam irradiation from the
Connecticut SEER Tumor *Registry* data base. Patients were treated
from 1973-1987, and those with Stages A1, A2 and D2 were excluded.
Patients ≤ 60 years of age had a 5-year survival rate of 72%
compared to 61% for those > 60 years of age ($p = 0.06$). When
stratified by race, white patients had a 63% 5-year survival rate
versus 47% in black patients ($p = 0.02$). When analyzed by race and
age, and age-race interaction was noted. Although younger whites
fared better than older whites, 77% versus 61% survival at 5 years ($p = 0.02$),
younger blacks fared worse than older blacks, 31% versus 52%
survival at 5 years ($p = 0.21$). Blacks, on average, presented at an
earlier age than whites, 65 years versus 69 years ($p = 0.001$). Both
races had similar stage and similar grade of disease. In older
patients, both races presented with similar stage and grade of
disease and had similar survival. However, in the younger age group,
black patients presented with similar grade, but higher stage disease
than whites. This may explain the worse survival in young blacks
compared to young whites, 31% versus 77% at 5 years ($p = 0.007$).
Multivariate analysis revealed that, even controlling for stage and
grade, blacks still fared worse than whites. Increased age was
associated with decreased survival in whites but increased survival
in blacks. Author-abstract.

LG German (GE).

AB The increased incidence of skin cancer recorded worldwide is alarming. The incidence of malignant melanoma has doubled in Germany every 10-15 years during recent decades, for example, as documented in the population-based cancer *registry* of the Saarland. In 1989, the incidence was 8.3 cases/100,000 inhabitants a year equally for both sexes. Non-melanoma skin cancer (basal cell and squamous cell carcinomas) showed a similar dramatic increase like melanoma and ranged in second place in the Saarland Cancer *Registry* in 1989, exceeded in men only by lung cancers and in women only by breast cancer. Their incidence was 93.4/100,000 in men and 55.8/100,000 in women. Epidemiological studies worldwide revealed a correlation between the increase of skin cancer incidence and UV exposure in white populations, and Caucasians living in regions near the equator are predominantly affected by this increase. Recently, incidence values for non-melanoma skin cancer in the USA were reported to be 232/100,000, whereas, for Queensland/Australia even numbers as high as 2398/100,000 (males) and 1908/100,000 (females) have been published. So far, the increase in skin cancer incidence has been related to changes in leisure time habits with increasing UV exposure. In this paper, an attempt is made to estimate any additional future risks for the development of skin cancer as a result of increasing UV *radiation* caused by stratospheric ozone depletion. Its reduction has been reported to be 3% over large areas of the globe (65 degrees North to 65 degrees South) according to the latest study of the United Nations Environment Programme.(ABSTRACT TRUNCATED AT 250 WORDS). PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB BACKGROUND. Malignant melanomas of the vulva and vagina are rare
tumors located in areas of the body not exposed to ultraviolet
radiation. Investigations comprising large consecutive
population-based series of patients with these diseases have not been
published previously, to the knowledge of the authors. METHODS.
Trends in incidence, age distribution, and prognosis were
investigated among 219 consecutive cases of malignant melanoma of the
vulva and 26 cases in the vagina, reported to the Swedish National
Cancer *Registry* and representing virtually all primary tumors of that
kind in Sweden during a 25-year period, 1960-1984. RESULTS. On
average, 75% of the patients with vulvar melanoma and 73% with
vaginal melanoma were older than 60 years of age. The mean age
increased slightly but not significantly during the period. The
age-standardized incidence of vulvar melanoma decreased from 0.27 to
0.14 per 100,000 Swedish women, or by 3% per year. The observed
5-year survival rate of patients with vulvar melanoma was 35%, and
the relative survival rate was 47%. The observed and relative
survival rates at 10 years were 23% and 44%, respectively. Observed
and relative survival rates among patients with vaginal melanoma
after 5 years were 13% and 18%, respectively. CONCLUSIONS.
Accordingly, there was a decreasing incidence of vulvar and vaginal
melanoma over the observed 25 years. This is in contrast to the
trends in incidence for cutaneous melanomas in Sweden, which, during
the same time period, increased almost 6% per year.

AB PURPOSE: Bone marrow transplantation is an effective treatment for leukemia. Cures are possible in 20-80% of transplant recipients depending on the stage of leukemia at the time of transplant. The antileukemia efficacy of transplants result from high-dose chemotherapy and/or *radiation* given pretransplant and from immune-mediated effects of the graft. RESULTS: Success of the procedure is limited by transplant-related complications, including graft rejection, graft-vs.-host disease and interstitial pneumonia. Five-year leukemia-free survival ranges from approximately 25% for children transplanted with advanced leukemia, to > 60% in those transplanted in first remission of acute leukemia or first chronic phase of chronic myeloid leukemia. CONCLUSIONS: Candidates for transplant include children failing conventional therapy and, possibly, those with early leukemia characterized by features predicting a poor response to conventional therapy.

TI Second cancer risk following testicular cancer: a follow-up study of 1,909 patients.

SO J-Clin-Oncol. 1993 Mar. 11(3). P 415-24.

JT JOURNAL OF CLINICAL ONCOLOGY.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB PURPOSE: Improved survival in testicular cancer has been accompanied by concern about long-term side effects of therapy. We assessed the evolution of second cancer (SC) risk over a prolonged follow-up period, which has been rarely studied in large patient series. PATIENTS AND METHODS: We estimated the risk of SCs in 1,909 patients with testicular cancer diagnosed in the Netherlands from 1971 to 1985. Complete medical information was obtained up to at least January 1988 for 92% of patients. Median follow-up was 7.7 years. For 89% of second tumors the diagnosis was confirmed through review of histologic slides; for an additional 8%, the diagnosis was verified by pathology reports only. RESULTS: Seventy-eight patients developed a SC 1 year or more after start of treatment, as compared with 47.6 expected on the basis of incidence rates in the general population (relative risk `RR:, 1.6; 95% confidence interval `CI:, 1.3 to 2.1). The mean 15-year actuarial risk of all SCs was 9.8% (95% CI, 7.5% to 12.8%). Significantly increased RRs were observed for all gastrointestinal cancers combined (RR, 2.6; 95% CI, 1.7 to 3.9), stomach cancer (RR, 3.7; 95% CI, 1.8 to 6.8), contralateral testicular cancer (CLTC) (RR, 35.7; 95% CI, 21.8 to 55.2), and leukemia (RR, 5.1; 95% CI, 1.4 to 13.0). Patients who had received irradiation to the paraaortic lymph nodes and who survived testicular cancer for more than 5 years were at particularly high risk of developing stomach cancer (RR, 6.9; 95% CI, 3.3 to 12.7). The median interval between the diagnosis of testicular cancer and stomach cancer was 12.4 years. Patients treated with chemotherapy (CT) did not experience an increase in SCs in general. Indeed, CT-treated

patients, as compared with those who received radiotherapy (RT), or surgery alone, had significantly reduced risk of CLTC. This finding might be attributed to an eradicating effect of CT on carcinoma in situ or subclinical CLTC. The excess risk of leukemia was not found to be clearly related to CT. CONCLUSION: Testicular cancer patients who receive RT experience elevated risk of gastrointestinal tumors. CT does not seem to increase SC risk and may even decrease the risk of a CLTC. Following testicular cancer, the 15-year actuarial risk of all SCs is only about half the risk experienced by patients with Hodgkin's disease. Author-abstract.

AB The immediate outcome of ELCA by XeCl excimer laser *radiation* is described in 53 patients who were selected to undergo ELCA from December 1990 to September 1991 in two centers that are currently performing ELCA in the Netherlands. Immediate success rates on the basis of visual assessment of the angiogram were as follows. Laser success (> 20% reduction of diameter stenosis after ELCA alone) was observed in 77% of patients, procedural success (< 50% residual stenosis after ELCA with or without adjunctive balloon dilatation `PTCA:') in 91%, and clinical success (procedural success without clinical complications) in 83% of patients. Quantitative coronary angiography by automated contour detection was performed in 31

patients who underwent ELCA in the Thoraxcenter. The minimal luminal diameter (mean +/- SD) of the treated coronary segments increased from 0.77 +/- 0.41 mm to 1.24 +/- 0.25 mm after ELCA and further to 1.67 +/- 0.29 mm after adjunctive PTCA in 25 patients. The present experience is put in perspective of results initially reported by other centers and compared with data from multicenter *registries* of ELCA. Finally, a short description is given of the design of a prospective, randomized trial of ELCA versus conventional PTCA (AMRO trial). Author-abstract.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB OBJECTIVE--To reappraise the epidemiological findings reported by the Black Advisory Group concerning a possible excess of malignant disease, particularly of childhood acute lymphoid leukaemia and non-Hodgkin lymphomas, in the vicinity of the Sellafield nuclear installation, and to determine whether any excess of malignant disease had occurred among people aged 0-24 years in the area in the years after the Black report--that is, from 1984 to 1990.

DESIGN--Calculation of incidence of cancer using data from population based cancer *registries* and special surveys. SETTING--England and Wales; county of Cumbria; county districts Allerdale and Copeland within Cumbria; Seascale ward within Copeland. SUBJECTS--All residents under the age of 75 years in the above areas, but with particular reference to those aged 0-24 years. MAIN OUTCOME MEASURES--Numbers of cases and incidence particularly of lymphoid leukaemia and non-Hodgkin lymphomas in those aged 0-24 years, but

including other cancers and age groups. RESULTS--Previous reports of an increased incidence of cancer, especially of leukaemia, among those aged 0-24 years in Seascale during the period up to and including 1983 are confirmed. During 1984-90 there was an excess of total cancer among those aged 0-24 years. This was based on four cases including two cases of non-Hodgkin lymphoma but none of leukaemia. There was an increased, but nonsignificant, incidence of other cancers, based on two cases (one pinealoma and one Hodgkin's disease) occurring among those aged 15-24 years during 1984-90. This was not observed in the younger age group or in previous years. For the immediately surrounding area--that is, the county districts of Allerdale and Copeland excluding Seascale and in the remainder of Cumbria--there was no evidence of an increased incidence of cancer among those aged 0-24 years in either period. CONCLUSIONS--During 1963-83 and 1984-90 the incidence of malignant disease, particularly lymphoid leukaemia and non-Hodgkin lymphomas, in young people aged 0-24 in Seascale was higher than would be expected on the basis of either national rates or those for the surrounding areas. Although this increased risk is unlikely to be due to chance, the reasons for it are still unknown. Author-abstract.

Crohn's disease. This longitudinal clinical information was reported

to the North American Home Parenteral and Enteral Nutrition *Registry* (Oley Foundation/A.S.P.E.N. joint project) between 1985 and 1989. The data shows that the number of active cancer patients on this therapy is increasing 13% per year. The annual survival rate is 25% for patients with active cancer, as compared with 88% for patients with *radiation* enteritis and 95% for patients with Crohn's disease. Although 50% of all active cancer patients starting HPN are dead within 6 to 9 months, the prognosis is somewhat better in children, and 20% of these active cancer patients appear to do well, returning to full oral nutrition and experiencing complete rehabilitation. These are presumed to be patients with a potentially curable cancer requiring super-aggressive treatment, which causes temporary severe gastrointestinal dysfunction. Adult active cancer patients have the same rehospitalization rate for HPN complications (once per year) as *radiation* enteritis and Crohn's disease patients. However, their rehospitalization rate for non-HPN complications is four times higher. This article reviews the factors that may explain the growth of HPN in active cancer patients and discusses some of the unanswered clinical questions that urgently need to be addressed to more effectively determine the appropriateness or inappropriateness of HPN management in the active cancer setting. Author-abstract.

JT BRITISH JOURNAL OF CANCER.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Thyroid cancer incidence has been increasing in many countries, whereas mortality has been falling due to better survival. *Radiation* is the best-established risk factor and there has been concern that recent rises in incidence might be related to fallout *radiation* from

atmospheric nuclear weapon tests. We examined thyroid cancer time trends and geographical distribution in England and Wales and possible interpretations of these. During 1962-84, there were significant increases in incidence ($P < 0.001$) in each sex at ages under 45. Cohort analysis by single year of birth showed an overall increase in incidence risks in women aged 0-44 born since 1920, with a sudden rise in risk for the birth years 1952-55 followed by a lower risk for the more recent cohorts. In men, there was an overall increase in risk at ages 0-44 in successive birth cohorts, but the pattern was irregular. In each sex, the risk in persons aged 45 and over decreased slightly in successive generations. Geographically, highest incidence risks were in countries in North and Mid Wales, in which the risk was almost twice that in the rest of the country. This pattern was present only at ages 45 and over and was most clear in rural areas. The peak of thyroid cancer risk in women born in 1952-55 is consistent with a carcinogenic effect of fallout *radiation,* since these women were children in the late 1950s and early 1960s when fallout *radiation* was greatest in England and Wales. The focus of high thyroid cancer risks in Wales was in areas with high levels of fallout *radiation.* However, thyroid cancer risks in Wales were not high for more recent cohorts (the ones who were exposed to fallout early in life), and a focus on high risk of benign thyroid diseases was present in Wales well before nuclear weapons existed. The distributions of these benign thyroid diseases, or of factors causing them, seem more likely than fallout to explain the high risk areas for thyroid cancer in the country. Author-abstract.

AB Photochemotherapy with psoralens + ultraviolet (UV)-A light (PUVA)

has been used for about 16 years to treat psoriasis. Some reports have indicated a higher frequency of cutaneous squamous cell carcinoma among treated patients. The results are not consistent, however, and are not generally conceded. Our material from Ulleval Hospital comprises 585 patients who have been treated with PUVA from 1977 until 1991. Three patients developed cutaneous squamous cell carcinoma, but in one of them the tumour developed before start of PUVA treatment. The two others had received only very small doses. One of them had an intraepithelial cancer of the penis. In addition we registered various internal cancers in 25 patients. The Norwegian Cancer *Registry* compared our patient material with a matched control group as regards sex, age and age-specific incidence rate. There was no statistically significant difference in incidence between the patient and the control group. Author-abstract.

AB PURPOSE: In the period 1968 through 1988, The Norwegian Radium Hospital (NRH) treated an unselected population of 1,152 patients with Hodgkin's disease (HD) that comprised more older patients (mean age, 43 years) than most other institutions. We considered it important to evaluate these patients for development of second cancers (SCs). PATIENTS AND METHODS: The Norwegian Cancer *Registry* identified previously untreated patients with HD treated at NRH who had developed a SC more than 1 year after diagnosis of HD. The relative risk ratio (RR) (observed/expected cases) and the cumulative risk were calculated. RESULTS: Sixty-eight patients had developed a SC, including nine acute nonlymphocytic leukemias (ANLLs), eight non-Hodgkin's lymphomas (NHLs), and 51 solid tumors, including 11 lung cancers. The RR of SC and leukemia was 1.86 (95% confidence interval `CI:, 1.4 to 2.4) and 24.3 (95% CI, 11.1 to 46.2),

respectively. The RR of SC was highest in younger patients (< 41 years, RR = 3.8). No significant association between splenectomy and development of ANLL was found. The influence of treatment and follow-up time on the development of SC agrees with data from other large cancer institutions. CONCLUSION: (1) The low RR of developing a SC in this study is probably due to the number of older patients included, who have a lower RR of developing a SC due to less aggressive treatment, shorter follow-up time, and higher incidence of cancer in the expected background population. (2) The low RR and cumulative risk of developing ANLL may be due to the limited use of extensive chemotherapy (CT) in our hospital in the earlier years. Author-abstract.

AB This study was undertaken to examine *radiation* treatment complications. From September 1987 through December 1989, 29,380 patients were screened at their follow-up visits for possible *radiation* complications. Of these patients, 1,380 were singled out for further study. These 1,380 charts were examined by a *radiation* oncologist and physicist to determine if there was a *radiation* complication, the severity of the complication, and whether a calculation or setup error could account for the complications. Of the 1,380 patients studied, 178 (3% of new patients treated each year) were determined to have *radiation* complications. These complications were divided into four categories of severity and entered into our computerized tumor *registry* as follows: complication type R1, complete recovery from symptoms, n = 59; R2, injury requiring medications to control injury, n = 104; S1, surgical intervention for one organ, n = 12; and S2, surgical intervention for

two organs, n = 3. We believe that a baseline complication rate of 5% is acceptable in *radiation* oncology practices. However, the examination and documentation of the outcome of care in the form of *radiation* complications can help improve patient care and keep the *radiation* oncologist abreast of treatment outcome trends in the department. PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Oral submucous fibrosis (OSMF) is a crippling disorder which is confined almost exclusively to the Indian subcontinent. Despite its association with a significantly increased risk of cancer, the etiology is still not clear. An epidemiological assessment showed 0.4% prevalence for OSMF in Kerala, South India, which is among the highest recorded. Recently the National Tumour *Registry* in Trivandrum reported the highest recorded site-specific incidence rate for oral cancer (ICD 140-145) in this area. The coastal belt of the Trivandrum and Quilon districts of Kerala has a very high natural radioactivity (over 1500 mR (387 microC) per year); about 500 mR (129 microC) per year is considered to be the maximum permissible dose for populations in general. An epidemiological survey in this area and in a comparable population (without exposure to high background *radiation*) as a control showed that the percentage prevalence of OSMF in the study area was 0.27 and in the control area 0.32. It appears highly improbable that the OSMF in the study area was induced by high background *radiation.* Author-abstract.

AB We studied changes in the prognosis of cancer of the rectum
(excluding the rectosigmoid junction) from 1978 to 1986 in the French
department of Calvados on the basis of the 616 cases in the cancer
registry. Taken as whole, survival has improved slightly with time
($P < 0.01$), but the improvement is only significant for men ($P < 0.02$),
patients under 70 years ($P < 0.01$) and patients living in
urban areas ($P < 0.05$). With regard to tumour characteristics, the
improvement was significant only for patients with Dukes' stage C
tumours at surgery ($P < 0.02$). To determine the reasons for the
improvement in survival, the year of diagnosis and all other
prognostic factors were studied in a multivariate model. Diagnostic
conditions such as age and tumour stage did not vary from 1978 to
1986; in contrast, the rates of tumour resection and adjuvant
radiation therapy increased, possibly explaining at least part of the
improvement, particularly for patients with Dukes' stage C tumours.

JAPONICAE.

PT JOURNAL-ARTICLE (ART).

LG Japanese (JA).

AB Clinical, pathological and follow-up data on 1,147 cases of retinoblastoma registered in Japan from 1975 to 1982 were statistically analysed. The cumulative survival rate of the 1,147 cases, calculated by the Kaplan-Meier method, was 93.0% at 5 years and 90.3% at 10 years. The survival rate of the 757 unilateral cases was 93.3% at 5 years and 92.3% at 10 years. For the 390 bilateral cases, however, the survival rate was 92.2% at 5 years and 86.7% at 10 years. A Cox multivariate analysis indicated that, among various clinical and pathological findings in the patients, extraocular invasion of the tumor is the most significant risk factor predictive of tumor death. The survival rate of those with extraocular invasion subsequently treated by local *radiation* and/or systemic chemotherapy was significantly better than the rate of those with extraocular invasion who did not receive aftercare. The cumulative incidence rate of second cancers in 409 cases of hereditary retinoblastoma was 4.8% at 10 years, 9.8% at 15 years and 15.7% at 20 years. The occurrence of a second cancer was the main cause of death in the hereditary cases after 10 years. Author-abstract.

TI Criteria for the use of Sartwell's incubation period model to study chronic diseases with uncertain etiology.

SO J-Clin-Epidemiol. 1992 Oct. 45(10). P 1071-80.

JT JOURNAL OF CLINICAL EPIDEMIOLOGY.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB This study explores the conditions under which Sartwell's incubation period model may be appropriate for identifying a primary time period of etiologic risk for chronic diseases with uncertain etiology. The investigation begins with a description of the evolution of the application of Sartwell's model from infectious to chronic diseases. The model's underlying assumptions and some concerns about its use in

the chronic disease context are specified. These concerns are addressed by data simulations and analyses of empirical data from the Connecticut Tumor *Registry* and the *Radiation* Effects Research Foundation. The results indicate that the distribution of age at diagnosis (i.e. onset) for chronic diseases is not necessarily lognormal. However, the representativeness of age distribution of the case series can affect the distribution's form; hence, it is important to determine the extent of "missing" cases, particularly those lost through truncation. Moreover, a lognormal age distribution may occur with both prenatal and age-related postnatal exposures. These findings suggest that only under certain conditions will Sartwell's model be useful in the study of chronic diseases of uncertain etiology, and indicate some caveats for interpretation of the results. Author-abstract.

TI Calculated risk of breast cancer following mantle irradiation determined by measured dose.

SO Cancer-Detect-Prev. 1992. 16(5-6). P 273-82.

JT CANCER DETECTION AND PREVENTION.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Tumor *registry* data indicate a two- to fourfold increased incidence of breast cancer following mantle irradiation, but cumulative risk is unknown. *Radiation* exposure to the breasts underlying the mantle block ranges from 4 to 40 Gy and is dependent on relative positions of the breasts and mantle block. Unshielded outer breast quadrants near axillary nodal regions receive 36 to 40 Gy, while central breast quadrants under the lung blocks receive approximately 4 Gy as determined by dose volume histogram analysis. Relative dose risk analysis for breast cancer following mantle irradiation was performed and indicated an overall excess risk of 1.5 for the upper outer quadrant (total dose 40 Gy), 1.3 for the upper and lower inner, and central quadrants (total dose 15 to 20 Gy), and 1.2 for the lower outer quadrant (total dose 4 Gy). Linear and cell-kill carcinogenesis models demonstrated similar relative risk assessments in the low-dose regions, defined as < 15 Gy. Predicted risk for

breast cancer in the high-dose regions ($>$ or $=$ 15 Gy) varied considerably according to the model evaluated. The linear model predicted a three to ten times greater risk above baseline breast cancer incidence for the high-dose regions. In contrast, the cell-kill model predicted no excess cases of breast cancer, assuming cell death at these higher dose levels. The greatest relative predicted risk is observed in women $<$ 20 years of age at the time of irradiation; however, women older than 20 years continue to have a 50% higher than baseline risk for subsequent breast cancer development. All women treated for Hodgkin's lymphoma should undergo dose volume histogram evaluation. Prospective clinical and mammographic evaluations should be performed in all female patients following mantle irradiation to better define the risk for secondary breast carcinogenesis. TI Meningeal hemangiopericytoma: defining the role for *radiation* therapy.

SO J-Neurooncol. 1992 Nov. 14(3). P 277-87.

JT JOURNAL OF NEURO-ONCOLOGY.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).

LG English (EN).

AB Meningeal hemangiopericytoma is a rare neoplasm arising from perivascular pericytes. Accounting for $<$ 1% of all brain tumors, these neoplasms are characterized by a high local recurrence rate and metastatic potential. Meningeal hemangiopericytoma occur most frequently during the fifth decade of life, with an almost equal sex incidence. To evaluate and define the role for primary, postoperative, or palliative radiotherapy in meningeal hemangiopericytoma, data were gathered from our own tumor *registry* and compiled with an extensive analysis of published series and case reports. This analysis reveals a 90%, 9 year actuarial risk for local recurrence following surgical resection only. Interestingly, less than 33% of these recurrences were noted within the first five years, which may account for the false assumption that these tumors

are highly curable with surgical resection only. *Radiation* therapy appears to reduce this local recurrence rate, prolonging disease-free and overall survival. *Radiation* responses are dose dependent, with > 50 Gray providing superior long-term disease-free survival.

Meningeal hemangiopericytoma are characterized by a slow, but progressive radiographic response to ionizing *radiation,* not unlike other radiated, highly vascular brain lesions, such as arteriovenous malformations. A retrospective review of clinical demographics, sites of meningeal origin, radiographic and pathologic findings and the role of chemotherapy is also presented. Author-abstract. 42 Refs.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB OBJECTIVE: To define the basis for the conflicting reports on the prognosis of lung cancer in young adults. DESIGN: Retrospective review of lung cancer patients between 1977 and 1988. SETTING: Medical centers in Chicago (Northwestern Memorial Hospital), northern Israel (Rambam Medical Center), and northern Italy (S. Anna and U. of Pavia Hospitals). PATIENTS: Patients were < or = 45 years of age with a diagnosis of primary lung cancer identified from tumor *registry* records, pathology reports, and hospital charts, plus a sample of patients > 45 years of age. MEASUREMENTS AND MAIN RESULTS: In Chicago, younger patients had a higher incidence of chest pain, fever, and neurologic symptoms at presentation than the older patients, and fewer were asymptomatic. They also had more lower lobe lesions on chest roentgenogram, a higher incidence of adenocarcinoma, more advanced disease, an increased likelihood of receiving chemotherapy, and reduced survival ($p < 0.03$). The poorer prognosis

was due to more advanced disease at presentation. In Israel, younger patients more frequently presented with stage I disease than the older patients and they had a higher incidence of adenocarcinoma, an increased likelihood of receiving treatment especially surgery, and better survival ($p < 0.02$). There were no differences between the two age groups for symptoms, symptom duration, and chest roentgenogram findings. Compared with the younger patients in Chicago and Israel, those from northern Italy had more squamous cell cancers and fewer adenocarcinomas, more commonly presented with stage I or II disease, received *radiation* therapy less frequently, and were given supportive care more often. Survival was low and comparable to that reported from Chicago. CONCLUSION: Differences exist in the clinical characteristics, pathologic findings, and prognosis of younger and older patients with lung cancer from the same region and of younger patients from different regions. The difference in prognosis is related in part to the stage of disease at presentation and the ability to undergo resectional surgery. Author-abstract.

 childhood leukaemia and lymphoma in Europe, in relation to the
 exposure to *radiation* which resulted from the accident at the

Chernobyl nuclear power plant in April 1986. In this first report, the incidence of leukaemia in children aged 0-14 is presented from cancer *registries* in 20 European countries for the period 1980-1988. Risk of leukaemia in 1987-1988 (8-32 months post-accident) relative to that before 1986, is compared with estimated average dose of *radiation* received by the population in 30 geographic areas. The observed changes in incidence do not relate to exposure. The period of follow-up is so far rather brief, and the study is planned to continue for at least 10 years. Author-abstract.

AB A case is presented of a 48-year-old male patient with thymic carcinoid tumor who was operated on twice and followed for 12 years. The original tumor was removed in 1979, and a recurrent tumor was removed 4 years later. Multiple metastases to the lungs, pleura and lymph nodes of the neck were found in 1988; chemotherapy (BAPP) and *radiation* therapy were not effective, and there was subsequent subcutaneous invasion of the anterior chest. We also discuss the 153 cases of thymic carcinoid tumor reported in the Japanese literature in the Niigata Carcinoid *Registry.* Author-abstract. 5 Refs.

AB BACKGROUND: There is strong epidemiologic evidence that psoriasis treatments may cause nonmelanoma skin cancer and possibly other types of cancer. OBJECTIVE: This study from Denmark reports the cancer incidence in 6910 patients with psoriasis discharged from the hospital from 1977 through 1987. METHODS: Patients were identified in the National Hospital Discharge Register and information on cases of cancer was obtained through the files of the Danish Cancer *Registry;* observed figures were compared with those expected on the basis of cancer incidence rates for the national population. RESULTS: A 2.5-fold increased risk was observed for nonmelanoma skin cancer in men and women, with no preponderance of any specific histologic subtype of cancer. In addition, excesses were seen of lung cancer in men (relative risk `RR = 1.4) and women (RR = 1.6), of cancer of the larynx and pharynx in men (RR = 2.8 and 3.9), and of colon and kidney cancer in women (RR = 1.6 and 2.3). CONCLUSION: The effect of cigarette smoking on the risk for noncutaneous cancer could not be assessed in this study; however, antipsoriatic treatment such as ionizing *radiation* and oral arsenicals must be considered as a possible cause of colon cancer, which has been observed in excess in two other studies of psoriatic patients. AB It is recognized that survivors of Hodgkin's disease are at a substantially increased risk of lung cancer. A collaborative group of population-based cancer *registries* and major treatment centers carried out a case-control study, in which 98 cases of lung cancer were identified in patients who had survived at least 1 year following a diagnosis of Hodgkin's disease. A total of 259 matched controls were selected from patients with Hodgkin's disease who did not develop subsequent lung cancer, and for both cases and controls detailed information was abstracted from medical records concerning stage and treatment of Hodgkin's disease. Patients treated with chemotherapy alone had about twice the risk of developing lung cancer than those treated by radiotherapy alone or both modalities. There was no increase in risk with cumulative number of cycles of chemotherapy. Among patients treated with radiotherapy alone, there was an increase in risk related to estimated *radiation* dose to the lung. There was also a strong association between cigarette smoking and the risk of lung cancer. The finding of a higher risk following chemotherapy than following radiotherapy was unexpected, but could not be explained by any identified methodological flaws. A plausible inference from the study is that all forms of Hodgkin's disease therapy are carcinogenic to the lung and that, in particular, chemotherapy is associated with an increase in risk which is at least comparable to and perhaps higher than the risk produced by radiotherapy. AB It is impossible to protect human heredity from the ecological
consequences of environmental pollution if there is no permanent
control of hereditary variability in human populations, i.e. genetic
monitoring. One of the urgent problems in genetic monitoring
planning is the magnitude of representative samples necessary for
establishing the significant mutation effect of environmental
factors. The elevation of the mutation frequency can be determined
either by the dynamics of the frequencies of hereditary pathology or
by comparison of the frequencies in populations that differ in
harmful factor exposures. Comparison of the effects evaluated by
cytogenetic, epidemiological (registration of congenital malformation
frequencies) and molecular-genetic methods in various population
groups will make it possible to solve the problem of safety in the
investigated regions. Author-abstract.

SO Arch-Dermatol. 1992 Oct. 128(10). P 1341-4.
JT ARCHIVES OF DERMATOLOGY.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB BACKGROUND AND DESIGN--There is an increasing concern about the long-term carcinogenic effect of oral psoralen with long-wave UV *radiation* in the A range (PUVA). Most follow-up investigations indicate a definite risk of squamous cell carcinoma of the skin with long-term PUVA treatment. In a recently published study of 4799 Swedish patients who had received PUVA, it was noted that 833 patients who had received trioxsalen bath or oral trioxsalen did not show any increased risk of skin cancer in contrast to oral methoxsalen. This finding has been further investigated in this study. We compared four dermatologic university clinics in Sweden with regard to the carcinogenic potential of the PUVA regimen used. One clinic used trioxsalen bath PUVA exclusively and the other three used oral methoxsalen. Information on their PUVA-treated patients was collected and linked with information from the Swedish Cancer *Registry* to identify individuals with squamous cell carcinoma of the

skin. RESULTS--A total of 18 squamous cell carcinomas of the skin were reported in 2975 PUVA-treated patients until 1987. The expected number was 3.1. The center using bath PUVA only had no increased risk of squamous cell carcinoma of the skin in contrast to the three centers using oral methoxsalen-PUVA. The increased risk for male subjects from those centers varied from six to 13 times that in the general population, but for female subjects a significant increased relative risk was found only at one center. CONCLUSION--In this preliminary report, PUVA treatment with trioxsalen bath seems to be less carcinogenic than the oral dosage. However, differences in the patient populations might also have affected the outcome of the study. More information on this field is needed. Author-abstract.

AB OBJECTIVES: We analyzed the influence of the radioactive fallout after the Chernobyl disaster on the rate and regional distribution of birth defects and abortion rates in southern Austria. STUDY DESIGN: During 1985 to 1989 a total of 66,743 births was monitored. Twelve sources provided data on 1695 cases of birth defects, 1579 of which were suitable for analysis. All cases were analyzed in terms of their calculated conception date and divided into three main groups according to their vulnerable phase of embryogenesis, spermatogenesis, and oogenesis. To study possible regional changes, the findings were plotted in 17 political subdistricts. The overall

abortion rate and the counseling frequency at termination clinics was determined. RESULTS: No significant changes in the incidence of birth defects, abortion rate, or counseling rate at pregnancy termination clinics were observed. CONCLUSIONS: Assessing the teratologic potential of low-dose *radiation* is difficult and requires adequate grouping of birth defects, sufficient baseline data, and highly reliable *registries.* Author-abstract.

AB In Norway, external doses of *radiation* resulting from fallout from the Chernobyl nuclear accident were estimated from detailed measurements, including soil deposition patterns. Internal doses were estimated from measurements of radioactive cesium in meat and milk supplies. The doses were calculated as average monthly doses for each of 454 municipalities during 36 consecutive months after the accident in spring 1986. Prospectively collected data on all newborns listed in the Medical Birth *Registry* of Norway who were conceived in the period May 1983-April 1989 were used to assess possible dose-response relations between estimated external and food-based exposures and congenital malformations and some other conditions. A positive association was observed between total *radiation* dose (external plus food-based) and hydrocephaly, while a negative association was observed for Down's syndrome. However, an important conclusion of the study was that no associations were found for conditions previously reported to be associated with *radiation,* i.e., small head circumference, congenital cataracts, anencephaly,

spina bifida, and low birth weight. Potential sources of bias, including exposure misclassification and incomplete ascertainment of cases, are discussed. Author-abstract.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB The Central Malignant Melanoma *Registry* (CMMR) of the German Dermatological Society was established in 1983, and 7789 cutaneous malignant melanomas (CMM) were registered by 35 dermatological departments in Germany, Austria and Switzerland until the end of 1989. Population-based incidence rates, risk factors for developing CMM and prognostic parameters for predicting the final outcome were investigated in separate multicenter studies performed by the CMMR. Among the 7789 CMM registered, there was a preponderance of females (57.7%) versus males (42.3%). The age distribution peaked in the 5th and 6th decade of life for both sexes with a mean age of 52 years. The mean detection age was 50 years for superficial spreading melanoma, 53 for nodular melanoma, and 65 for lentigo maligna melanoma. Mean tumor thickness decreased from 2 mm in 1983 to 1.5 mm in 1989, indicating better CMM-awareness of the population and the medical community in this area. 90% of the patients presented with clinical stage I CMM without detectable metastases at first diagnosis. The incidence of CMM in Berlin (West) was assessed based on 960 cases diagnosed between 1980 and 1986. The incidence increased by 49% between 1980-81 and 1985-86, and the age standardized-incidence rate (European standard population) was 9.8

for males and 7.8 for females per 100,000 inhabitants and year in 1985-86. Mortality rates decreased in this period from 3.5 to 2.6 for males and slightly increased for females from 1.2 to 1.6 per 100,000 inhabitants and year. A case control study on the relative risk (RR) for developing CMM revealed the total number of melanocytic nevi (MCN) to be the strongest risk predictor (15x -50x increased RR), followed by the presence of dysplastic MCN (7x increased RR) and the skin type I (2x increased RR). Interestingly, no differences between CMM-cases and controls were found with respect to the history of sunburns or other parameters of sun exposure in this study. Multivariate analysis of 5093 stage I CMM-patients from four departments with long-term follow-up revealed that tumor thickness is the strongest predictor of survival with an almost linear correlation to the risk of death for tumor thickness up to 6 mm with no further increase in mortality for higher tumor thickness. The best classification of tumor thickness for survival prediction was less than or equal to 1 mm, 1.01-2 mm, 2.01-4 mm and greater than 4 mm in our data set on 5093 patients.(ABSTRACT TRUNCATED AT 400 WORDS).

TI Controversy pertaining to therapeutic modalities for tumors of the
pineal region: a worldwide survey of different patient populations.

SO Childs-Nerv-Syst. 1992 Sep. 8(6). P 332-6.

JT CHILDS NERVOUS SYSTEM.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB The management of tumors of the pineal region differs between Western countries and Japan. This paper reports on a worldwide survey of individual experience and regimens for treating pineal region tumors in different patient populations. Fifteen pediatric neurosurgeons from nine different countries participated in the survey, and a total of 408 pineal region tumors were evaluated. Determination of tumor histology as an initial procedure was strongly supported by the majority of neurosurgeons in North and Central America and Europe (group A), whereas all but one from Asia and Egypt (group B) emphasized initial application of the *radiation* test. The analysis of patient populations clearly revealed racial differences in tumor type which explain this discrepancy. Germinoma, the most radiosensitive tumor, constituted 43-70% (mean: 53.7%) of tumors in group B, followed by teratoma, pineoblastoma, and others, whereas in group A the incidence of germinoma was only 21-44% (mean: 34.7%), followed by a variety of tumors, such as astrocytoma, pineoblastoma, etc. The age distribution among intracranial germ cell tumors (GCT) obtained from data from the Brain Tumor *Registry* in Japan also demonstrated clear differences in the incidence of tumor types in different age groups in Japan: while germinoma constituted 70-84% of GCT in patients between the ages of 15 and 35 years, the incidence was much lower before 15 years and after 35 years, being 24% of tumors under 4 years and 34% of tumors after 40 years of age. The therapeutic regimen for pineal region tumors should depend on the patient population concerned, because of the differences relating to race and age distribution. Author-abstract.

TI Cancer risk following exposure to Thorotrast: overview in relation to
a case report.
SO Health-Phys. 1992 Jul. 63(1). P 89-97.
JT HEALTH PHYSICS.
PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).
LG English (EN).
AB Radioactive measurements and histopathologic findings are described
in a patient administered Thorotrast, a radiographic contrast agent,
36 y prior to death and compared with cancer risks noted in
epidemiologic studies. This person designated as U.S. Uranium
Registry (USUR) Case 1001: had prearranged for donation of her body
to the USUR and the National Cancer Institute for study. Elevated
levels of radioactivity were noted in those organs in which excess
cancers have been reported in epidemiologic surveys of
Thorotrast-exposed subjects. Hepatic tissue in USUR Case 1001 was
estimated to have received an average lifetime absorbed dose of 16.2
Gy, based on radiochemical analyses, consistent with the high risks
for liver tumors reported in all studied populations. Thorotrast was
present throughout the bone marrow of USUR Case 1001, who died
secondary to complications of refractory anemia with excess blasts
(RAEB). Elevated risks for acute myeloid leukemia have been noted in
Thorotrast patients, and more recently, cases of RAEB and RAEB in
transformation have been reported. The thorium decay series includes
the bone-seeking radionuclides 224Ra and 228Ra, which have been
associated with high risks for osteosarcomas, although the
association between Thorotrast and bone cancer is not as convincing.
The skeleton of USUR Case 1001, however, contained significant levels
of radioactivity. Other tissues evaluated in USUR Case 1001 included
lung, eye, kidney, and breast, which did not contain elevated levels
of radioactivity. Author-abstract. 44 Refs.

TI Distribution and dosimetry of Thorotrast in USUR case 1001.
SO Health-Phys. 1992 Jul. 63(1). P 72-88.
JT HEALTH PHYSICS.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB The distribution of radioactivity and the associated doses were evaluated postmortem for USUR Case 1001, a female who had been injected with Thorotrast some 36 y prior to death. The distribution was determined for four nuclides: ²³²Th and its decay products, ²²⁸Ra and ²²⁸Th; and ²³⁰Th, a contaminant associated with Thorotrast. More than 90% of the activity was associated with the reticuloendothelial system. Approximately 32% of the total activity was found in the total skeleton (mineral bone and bone marrow), which is somewhat higher than expected from the literature. The 44% found in the liver and 12% in the spleen were somewhat lower than expected. This difference may be attributable, in part, to the initial deposition as influenced by colloidal particle size and to the *radiation-induced* hyposplenism, splenic atrophy, and slight hepatic atrophy observed at autopsy. In addition, roughly 3% of the activity was found in the Thorotrastoma and surrounding carotid artery tissue. Estimated lifetime absorbed doses from the ²³²Th series were 15 Gy to the liver, 121 Gy to the spleen, 4 Gy to the skeleton, and 16 Gy to the Thorotrastoma. Comparable dose equivalents to these tissues are 300, 2420, 80, and 320 Sv, respectively, assuming a quality factor of 20 for alpha irradiation. Author-abstract.

AB Cancer may be serious late effect of marrow transplantation.
Radiation, chemotherapy, immunosuppression and the original disease
for which transplantation was performed may predispose to the
development of cancer. 116 of 9732 patients reported to the IBMTR
(International Bone Marrow Transplant *Registry)* have developed a new
malignancy. Late effects were evaluated by the EBMT-EULEP (European
Bone Marrow Transplant-European Late Effect Project) Late Effect
Study Group in 147 patients surviving 6 years and 79 patients
surviving more than 10 years. New malignancies developed in 11 of
these patients. Lymphomas and leukemia comprised 73 cases reported
to the IBMTR and one case reported to the EBMT-EULEP study. Tumors
of the skin, oropharynx, vulva vagina and cervix prevailed in 41
patients with solid tumors. The distribution of malignancies is
similar to that observed in organ transplant patients not given
radiation or chemotherapy and suggests immunosuppression as a major
contributory factor. In dogs the incidence of malignancies was
studied after either chemotherapy or total body *radiation* in various
regimens and marrow transplantation. Both chemotherapy and *radiation*
shortened tumor-free survival in comparison to untreated dogs.
Higher doses, larger fractions and shorter treatment schedules
enhanced earlier tumor development. Soft tissue sarcomas and thyroid
carcinoma were most frequent in treated, mammary carcinoma in
untreated dogs. In treated dogs deaths from cancer were observed
starting at the age of 5 years as compared to untreated dogs at the
age of 9 years. The data from animal experiments indicate that the
incidence of solid tumors in marrow transplant patients may still
rise in the coming decades. Author-abstract.

TI Survival rate and risk factors for patients with retinoblastoma in Japan. The Committee for the National *Registry* of Retinoblastoma.
SO Jpn-J-Ophthalmol. 1992. 36(2). P 121-31.
JT JAPANESE JOURNAL OF OPHTHALMOLOGY.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Clinical, pathological and follow-up data on the 1,147 cases of retinoblastoma registered in Japan from 1975 to 1982 were statistically analyzed. The cumulative survival rate of the total 1,147 cases was 93.0% at 5 years and 90.3% at 10 years, calculated by the Kaplan-Meier method. The survival rate for the 757 unilateral cases was 93.3% at 5 years and 92.3% at 10 years. For the 390 bilateral cases, however, the rate was 92.2% at 5 years and 86.7% at 10 years. The Cox multivariate analysis indicated that, among the various clinical and pathological findings in the patients, extraocular invasion by the tumor was the most significant risk factor which is predictive of death due to tumor. The survival rate for patients with extraocular invasion was significantly better in cases undergoing subsequent local *radiation* and/or systemic chemotherapy than in cases without such aftercare. The cumulative incidence rate of second neoplasms in 409 cases of hereditary retinoblastoma was 4.8% at 10 years, 9.8% at 15 years and 15.7% at 20 years. The occurrence of a second neoplasm was the main cause of death in the hereditary cases 10 years after the first onset.

TI Second cancers in patients with chronic lymphocytic leukemia.

SO J-Natl-Cancer-Inst. 1992 Sep 16. 84(18). P 1422-7.

JT JOURNAL OF THE NATIONAL CANCER INSTITUTE.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB BACKGROUND: Reports to date have provided widely divergent estimates of the risk of second malignant neoplasms in patients with chronic lymphocytic leukemia (CLL), ranging from cancer deficits to excesses of twofold to threefold. PURPOSE: Our purpose was to estimate the risk of second primary cancers following CLL, utilizing population-based tumor *registries,* and to determine whether site-specific excesses might be associated with type of initial treatment for CLL. METHODS: We analyzed data for 9456 patients diagnosed with CLL as a first primary cancer between 1973 and 1988, who were reported to one of nine tumor *registries* participating in the National Cancer Institute's Surveillance, Epidemiology, and End Results (SEER) Program and who survived 2 or more months. SEER files were searched for invasive primary malignancies that developed at least 2 months after the initial CLL diagnosis. RESULTS: Compared with the general population, CLL patients demonstrated a significantly increased risk of developing all second cancers (840 observed; observed-to-expected ratio $O/E = 1.28$; 95% confidence interval $CI = 1.19-1.37$). Significant excesses were noted for cancers of the lung ($O/E = 1.90$), brain ($O/E = 1.98$), and eye (intraocular melanoma) ($O/E = 3.97$) as well as malignant melanoma ($O/E = 2.79$) and Hodgkin's disease ($O/E = 7.69$). Cancer risk, which did not vary according to initial treatment category, was also constant across all time intervals after CLL diagnosis. CONCLUSION: CLL patients are at a significantly increased risk of developing a second malignant neoplasm. The pattern of cancer excesses suggests a susceptibility state permitting the development of selected second malignancies in patients with CLL, perhaps because of shared etiologic factors, immunologic impairment, and/or other influences. Although our results do not suggest a strong treatment effect, more detailed studies of second tumors in CLL are needed to investigate the role of *radiation* therapy and chemotherapy. AB From a total of 18,416 bone-marrow biopsy reports entered into the Dusseldorf Bone Marrow *Registry* between 1975 and 1990 those of patients diagnosed as having preleukaemia, myeloid dysplasia, panmyelopathy with hypercellular bone marrow, refractory anaemia, sideroblastic anaemia or smoldering leukaemia were reanalyzed together with patient-data. If the diagnosis of myelodysplastic syndrome (MDS) was confirmed, the original blood and bone-marrow smear was re-examined and classified, 584 cases in all (3.2%). During the same period acute myeloid leukaemia had been diagnosed in 506 patients (2.8%). The average annual incidence of MDS in the Dusseldorf area was 3.65 per 100,000 inhabitants. Over 80% of cases occurred from the age of 60 years, while 7% were younger than 50 years. The sex ratio was the same in all subgroups of MDS, except chronic myelomonocytic leukaemia (male:female ratio 1:1.57). 31 patients (5.3%) had received ionizing *radiation* and/or cytostatic or immunosuppressive treatment for various underlying diseases before MDS had been diagnosed (secondary MDS). Preceding occupational contact with organic solvents could not be excluded with certainty in 12 patients. These data suggest that MDS is a relatively frequent disease of hematopoiesis among the older age groups. The proportion of secondary (treatment-induced) forms is small and does not explain the recently observed increased incidence. Author-abstract.

JT JOURNAL OF THE NATIONAL CANCER INSTITUTE.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB BACKGROUND: Studies of groups of patients given injections of the alpha-emitting x-ray contrast medium Thorotrast may provide information on human alpha-ray carcinogenesis. PURPOSE: We re-established a formerly identified cohort of neurological patients receiving injections of Thorotrast for cerebral arteriography and assessed their incidence of cancer. METHODS: Using the national population register, the Danish Cancer *Registry,* and other registers, we determined the incidence of cancer among Thorotrast-injected patients. Incidence ratios were standardized to the general population and computed for different cancer sites. RESULTS: The cumulative risk for cancer at all sites (excluding brain tumors where the standardized incidence ratio `SIR: was 28) reached 86% 50 years after Thorotrast injection. SIR was greatly elevated at all sites except the brain and CNS (3.3, 95% confidence interval = 3.0-3.7), mainly because of liver cancers (SIR = 126) as well as leukemia (SIR = 10) for which a relationship was found between the time since injection and the estimated dose (but not the age at injection). Other sites with significantly increased risks of cancer included the gallbladder and extrahepatic bile ducts (SIR = 14), peritoneum (SIR = 8.6), sites of multiple myeloma (SIR = 4.6), metastatic sites (SIR = 12), and unspecified sites (SIR = 11). Cancers of the lung and breast also occurred in significant excess, but no relationship between SIR and volume of injected Thorotrast or time since injection was observed. Cancer risk was increased at most other sites, although this increase was not statistically significant. CONCLUSION: Alpha *radiation* may account for the increased risk of tumors of the liver, gallbladder, and peritoneum as well as leukemia and multiple myeloma, whereas confounding factors most probably contribute to the increased risks at other sites. SO J-Natl-Cancer-Inst. 1992 Aug 19. 84(16). P 1245-50.
JT JOURNAL OF THE NATIONAL CANCER INSTITUTE.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB BACKGROUND: The risk of contralateral breast cancer is increased
twofold to fivefold for breast cancer patients. A *registry-based*
cohort study in Denmark suggested that *radiation* treatment of the
first breast cancer might increase the risk for contralateral breast
cancer among 10-year survivors. PURPOSE: Our goal was to assess the
role of *radiation* in the development of contralateral breast cancer.
METHODS: A nested case-control study was conducted in a cohort of
56,540 women in Denmark diagnosed with invasive breast cancer from
1943 through 1978. Case patients were 529 women who developed
contralateral breast cancer 8 or more years after first diagnosis.
Controls were women with breast cancer who did not develop
contralateral breast cancer. One control was matched to each case
patient on the basis of age, calendar year of initial breast cancer
diagnosis, and survival time. *Radiation* dose to the contralateral
breast was estimated for each patient on the basis of *radiation*
measurements and abstracted treatment information. The anatomical
position of each breast cancer was also abstracted from medical
records. RESULTS: Radiotherapy had been administered to 82.4% of
case patients and controls, and the mean *radiation* dose to the
contralateral breast was estimated to be 2.51 Gy. Radiotherapy did
not increase the overall risk of contralateral breast cancer
(relative risk = 1.04; 95% confidence interval = 0.74-1.46), and
there was no evidence that risk varied with *radiation* dose, time
since exposure, or age at exposure. The second tumors in case
patients were evenly distributed in the medial, lateral, and central
portions of the breast, a finding that argues against a causal role
of radiotherapy in tumorigenesis. CONCLUSIONS: The majority of women
in our series were perimenopausal or postmenopausal (53% total versus
38% premenopausal and 9% of unknown status) and received radiotherapy
at an age when the breast tissue appears least susceptible to the
carcinogenic effects of *radiation.* Based on a dose of 2.51 Gy and
estimates of *radiation* risk from other studies, a relative risk of
only 1.18 would have been expected for a population of women exposed
at an average age of 51 years. Thus, our data provide additional

evidence that there is little if any risk of *radiation-induced* breast cancer associated with exposure of breast tissue to low-dose *radiation* (e.g., from mammographic x rays or adjuvant radiotherapy) in later life. Author-abstract.

AB A retrospective study examining the influence of young age, defined as 30 years or less on the outcome of early-staged (American Joint Committee 1978-I, II) breast cancer was undertaken using patients treated between 1950 and 1970 to ensure a long follow-up period. Because of the era of treatment, radical mastectomy without systemic chemotherapy was the predominant treatment. Ninety-nine patients met study criteria, with a median follow-up of 11.4 years (range 0.5 to 41 years). The patient group was compared to patients of all ages, treated at Memorial Sloan-Kettering Cancer Center in 1960 (5 and 10 years) and to patients treated between 1940 and 1943 (30 year follow-up). At the 5, 10, and 30 year follow-up periods, patients in the young age group consistently had disease-specific survival 10-20% lower than their older counterparts. For young patients who survived their first cancer diagnosis, second primaries both in the contralateral breast and elsewhere, played a significant role in determining their subsequent life span. When compared to risks of second primary cancers in the National Cancer Institute's SEER (Surveillance, Epidemiology and End Results Program) Cancer *Registry* for all ages, the increased risk for very young breast cancer patients was significant ($p = 0.000$). With these two findings in

mind, treatment for young patients with breast cancer should focus not on local therapy options alone but on the increased risk of both systemic disease and of second primaries. Author-abstract.

AB OBJECTIVES. Treatment and mortality risk were compared between prostate cancer patients receiving care in fee-for-service settings and those receiving care in a health maintenance organization (HMO). METHODS. Two samples were obtained from a population-based tumor *registry.* Patients in the first sample (n = 201) were interviewed shortly after diagnosis to obtain data on income, education, overall health status, and expenditures for health status, and expenditures for health care. These data were combined with information from the tumor *registry* on cancer stage, age, treatment, place of residence, and source of care. Only tumor *registry* data were obtained for most patients in the second sample (n = 962). For both samples, survival time was monitored for up to 80 months. RESULTS. Multivariate analysis of data from the interviewed sample indicated that HMO patients were less likely to receive surgery but more likely to receive *radiation* therapy than were those in fee-for-service settings. Mortality risk was lower for the HMO patients than for those in fee-for-service plans. Findings based on the second sample were nearly identical. CONCLUSIONS. This study suggests that HMOs may offer important advantages to lower-income patients at risk for specific life-threatening diseases. Author-abstract.

AB OBJECTIVE--To identify changes in practice and outcome of bone marrow
transplants for leukemia in the 1980s. DESIGN--Comparison of key
explanatory and outcome variables in five 2-year cohorts, from 1980
through 1981 to 1988 through 1989, using a large database of detailed
clinical information. PATIENTS--Recipients (7788) of bone marrow
transplants for acute lymphoblastic, acute myelogenous, or chronic
myelogenous leukemia reported to the International Bone Marrow
Transplant *Registry,* Milwaukee, Wis, by 185 transplant teams
worldwide. RESULTS--Linear increases occurred during the periods
1980 through 1981 to 1988 through 1989 as follows with 95% confidence
intervals: (1) transplants for chronic myelogenous leukemia from 14%
+/- 2% to 35% +/- 2%; (2) transplants from unrelated donors from 1%
+/- 1% to 7% +/- 1%; (3) preparative regimens without *radiation* from
3% +/- 1% to 30% +/- 2%; and (4) use of methotrexate plus
cyclosporine to prevent graft-vs-host disease from 2% +/- 1% to 55%
+/- 2%. Among recipients of human lymphocyte antigen-identical
sibling bone marrow, the 2-year probability of treatment-related
mortality decreased by 6% to 22%. The probability of relapse
decreased from 46% +/- 6% to 38% +/- 6% in intermediate leukemia but
did not change appreciably in early or advanced leukemia.
Probabilities of leukemia-free survival improved from 51% +/- 4% to
57% +/- 3% in early leukemia, from 28% +/- 4% to 36% +/- 5% in
intermediate leukemia, and from 12% +/- 4% to 18% +/- 5% in advanced
leukemia. A separate analysis of a homogenous population of patients
indicated that improvements in outcome in the 1980s were due to
improvements in transplant practice rather than improved patient
selection. CONCLUSIONS--Modest increases in leukemia-free survival

rates occurred after human lymphocyte antigen-identical sibling bone marrow transplants in the 1980s. Improvements were due primarily to reductions in treatment-related mortality with little or no change in relapse risk. More effective antileukemia strategies and continued reductions in treatment-related toxic effects are needed.

TI Second malignancies in very-long-term survivors of childhood cancer.
SO Am-J-Med. 1992 Jul. 93(1). P 57-60.
JT AMERICAN JOURNAL OF MEDICINE.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB PURPOSE: Although most second malignancies are treatment related,
their occurrence also may be due to an underlying systemic disease or
chromosomal abnormalities shared by multiple organs in which they are
tumorigenic. We attempted to identify unusual tumor pairs that might
provide a clue to shared genetic etiologies. PATIENTS AND METHODS:
Medical records and tumor *registry* correspondence of 1,743 patients
(0 to 18 years at diagnosis) were reviewed. For those said to have
a second malignancy, biopsy and autopsy records and slides were
reviewed to confirm initial and secondary diagnoses. RESULTS: Two
hundred fifty-eight patients had follow-up of at least 10 years and
157 of at least 20 years. Second malignancies were identified in 14
patients. The estimated cumulative incidence of a second cancer was
approximately 1% within 10 years. At 20 years after diagnosis, the
actuarial estimate was 3%. Although most second cancers were likely
treatment related, several tumor pairs could not clearly be explained

on that basis, including thyroid carcinoma followed by an ovarian sarcoma, and acute lymphoblastic leukemia associated with renal leiomyosarcoma. Based on one case in this series and a review of the literature, associations between Wilms' tumor, abdominal *radiation,* and adenocarcinoma of the colon and hepatocellular carcinoma are suggested. CONCLUSIONS: We conclude that continued surveillance of very-long-term survivors of childhood cancer, which is usually accomplished by internists, family practitioners, and adult oncologists, may be one approach to defining the life-time incidence of second malignancies. In addition, although the yield is likely to be small, descriptions of unexpected tumor pairs may target families for studies of pleiotropic genetic abnormalities. Author-abstract.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB The occurrence of new primary tumours among postmenopausal patients with primary breast cancer subsequent to adjuvant treatment in Denmark was assessed by linkage to the cancer *registry.* Following primary surgery, patients in low risk of recurrence (n = 1,828) received no further treatment while patients in high risk randomly received either adjuvant radiotherapy alone (n = 846) or radiotherapy + tamoxifen 30 mg daily for 48 weeks (n = 864). With a median follow-up of 8 years, the incidence of tumours in the contralateral breast was similar among tamoxifen-treated, and non-treated high-risk patients even after adjusting for tumours arising within the first year. The standardized incidence ratio for endometrial cancer was 1.9 (95% confidence interval 0.8-3.9) among tamoxifen treated, the cumulative incidence 1% compared to 0.3% among non-treated patients

(p = 0.11). The cumulative risk of non-lymphocytic leukaemia was 0.9% and 0.1% among irradiated and non-irradiated patients respectively (p = 0.4). Prolonged follow-up of tamoxifen-treated patients with regard to new tumours is recommended.

AB The incidence of childhood malignancies in 20 areas surrounding major
nuclear installations is compared with the incidence in matched
control regions. The study is based on the *registry* of childhood
malignancies in the Federal Republic of Germany and includes 1,610
cases which were diagnosed before 15 years of age from 1980 to 1990.
The relative risk (RR) was 0.97 for all malignancies and 1.06 for
acute leukemia in all regions within a 15 km radius of an
installation. Increased RR was observed in subgroups for acute
leukemia before five years of age and for lymphomas, especially in
regions close to installations (less than 5 km) which started
operation before 1970. Most of this increase was attributable to an
unexpectedly low incidence in the control regions which could not be
explained by analyzing possible confounding factors. Using the same
control regions, a comparable and even more pronounced increase of
RRs was observed in regions where nuclear power plants have been
projected. Author-abstract.

TI Leukaemia incidence after iodine-131 exposure.

SO Lancet. 1992 Jul 4. 340(8810). P 1-4.

JT LANCET.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Leukaemia is one of the most prominent late effects of exposure to ionising *radiation.* We have studied the incidence of leukaemia among 46,988 Swedish patients exposed to iodine-131 (131I) for diagnostic reasons or to treat hyperthyroidism or thyroid cancer. The observed number of leukaemias was compared with that expected based on incidence data from the general population. The mean absorbed dose to the bone marrow was estimated as 14 mGy (range 0.01-2.226). 195 leukaemias occurred more than 2 years after exposure, and the standardised incidence ratio (SIR) was 1.09 (95% confidence interval 0.94-1.25). Similar, but again not significantly, increased risks were seen for chronic lymphocytic leukaemia (CLL) (SIR = 1.08), a malignant condition not found to be increased after irradiation, and for non-CLL (SIR = 1.09). The risk of leukaemia did not vary by sex, age, time, or *radiation* dose from 131I. One reason for the absence of a *radiation* effect, other than chance, includes the possible lowering of risk when exposure is protracted over time as occurs with 131I. Excess leukaemia risks of more than 25% could thus be excluded with high assurance in this population of mainly adults. These results should be reassuring to patients exposed to 131I in medical practice and to most individuals exposed to the fall-out from the Chernobyl accident. Author-abstract.

LG English (EN).

AB The prognosis in nephroblastoma (Wilms' tumor) has been improved considerably by treatment protocols combining surgery, chemotherapy, *radiation* therapy, and, in some clinical trials, pre-operative chemotherapy. Cure is now achieved in most patients. All clinical trials have employed treatment strategies tailored to the individual risk of the patient, including the histological subtype of the tumor. In the National Wilms' Tumor Study (NWTs) of the United States these subtypes have been divided into two groups of tumors according to their "favorable" or "unfavorable" histology. At the Kiel Pediatric Tumor *Registry* we have devised a system which distinguishes three groups of tumors classified according to prognosis. The first group includes tumors with a favorable prognosis, even if only surgery is performed. These comprise congenital mesoblastic nephroma (CMN) and cystic, partially differentiated nephroblastoma (CPDN). The second group consists of tumors posing an intermediate risk, such as typical nephroblastoma and its histological variants characterized by variations in the relative proportions of the histological components. Fetal rhabdomyomatous nephroblastoma (FRN) is also included in this group. The third group comprises tumors of high risk such as anaplastic nephroblastoma, clear cell sarcoma of the kidney (CCSK), and malignant rhabdoid tumor of the kidney (MRTK). Since histological diagnosis plays a crucial role in the assignment of a patient to a particular type of treatment protocol, knowledge of the histological appearance of the various tumor types both with and without preoperative treatment is of utmost importance.

TI Trends in childhood leukaemia in the Nordic countries in relation to fallout from atmospheric nuclear weapons testing.

SO BMJ. 1992 Apr 18. 304(6833). P 1005-9.

JT BMJ.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB OBJECTIVE--To obtain further information about the risks of childhood leukaemia after exposure to ionising *radiation* at low doses and low dose rates before or after birth or to the father's testes shortly before conception. DESIGN--Observational study of trends in incidence of childhood leukaemia in relation to estimated *radiation* exposures due to fallout from atmospheric nuclear weapons testing during the 1950s and 1960s. SETTING--Nordic countries. SUBJECTS--Children aged under 15 years. MAIN OUTCOME MEASURES--Incidence rates of leukaemia by age at diagnosis, sex, country, and calendar year of diagnosis or year of birth; exposure category; relation between leukaemia and exposure for children aged 0-14 and 0-4 separately. RESULTS--During the high fallout period the average estimated dose equivalent to the fetal red bone marrow was around 140 mu Sv and the average annual testicular dose 140 mu Sv. There was little evidence of increased incidence of leukaemia among children born in these years. Doses to the red bone marrow of a child after birth were higher, and during the high exposure period children would have been subjected to an additional dose equivalent of around 1500 mu Sv, similar to doses received by children in several parts of central and eastern Europe owing to the Chernobyl accident and about 50% greater than the annual dose equivalent to the red bone marrow of a child from natural *radiation.* leukaemia incidence and red marrow dose was not related overall, but rates of leukaemia in the high exposure period were slightly higher than in the surrounding medium exposure period (relative risk for ages 0-14: 1.07, 95% confidence interval 1.00 to 1.14; for ages 0-4: 1.11, 1.00 to 1.24). CONCLUSIONS--Current predicted risks of childhood leukaemia after exposure to *radiation* are not greatly underestimated for low dose rate exposures. Author-abstract.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB From January 1977 through December 1989, a total of 1,569 patients
with pharyngolaryngeal cancer (oropharynx: 240, nasopharynx: 221,
hypopharynx: 246, and larynx: 862) were treated at the Department of
Radiology, Osaka University Hospital and the Department of *Radiation*
Therapy, The Center for Adult Diseases, Osaka. The incidence of
other primary cancers in these patients was investigated using the
data base of *radiation* therapy combined with information from
hospital-based and Osaka prefectural cancer *registries.* One hundred
and seventy-six of the 1,569 patients (11%) had other primary cancers
(oropharynx: 21%, nasopharynx: 7%, hypopharynx: 13%, and larynx: 9%).
The time of development of other primary cancers in more than 50% of
the cases ranged between one year before and one year after the
diagnosis of primary pharyngolaryngeal cancer. The expected number
of the second primary cancer was estimated by multiplying the age-sex
specific incidence rates for Osaka residents with person-years at
risk based on Osaka prefectural cancer *registry* data. The
observed/expected (O/E) ratios were 3.17 (p less than 0.01) for
oropharyngeal, 2.01 (p less than 0.01) for nasopharyngeal, 2.16 (p
less than 0.01) for hypopharyngeal and 1.10 (n.s.) for laryngeal
cancer. The most common sites of the second primary cancer in order
of frequency were: the oral cavity and pharynx, esophagus and lung
for oropharyngeal cancer, the oral cavity and pharynx for
nasopharyngeal cancer, the oral cavity and pharynx and the esophagus
for hypopharyngeal cancer and the oral cavity and pharynx, esophagus
and lung for laryngeal cancer. Author-abstract.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB From 1967 to 1990, 96 previously untreated patients with
cervicovaginal cancer associated with a history of vaginal pessary
use to control uterovaginal prolapse were referred to eight *radiation*
therapy departments in France. Sixty-eight patients had cervical
cancer, and 28 had vaginal cancer. The mean interval between pessary
insertion and cancer diagnosis was 18 years, with a range of 1 to 41
years. Most patients received *radiation* therapy and brachytherapy.
Few (5%) had Grade 3 treatment side effects. The overall 5-year
relative survival rate was 54%; nonsurvival was related to
locoregional recurrence. Because almost all tumors occurred at the
site of pessary insertion, foreign body chronic inflammation in
association with viral infection may be the cause of the tumors.

AB Cancer mortality risks for individuals who were employed at nuclear facilities in Tarapur and for their respective family members with whom they lived were examined. Cancer deaths that occurred in this population between 1971 and 1988 were compared with death rates published by the Bombay City Cancer *Registry.* Risks were expressed as standardized mortality ratios (SMRs), which were computed by dividing the observed number of deaths by the expected number of deaths and multiplying this value times 100. There were 11 deaths from cancer among the employees, and this figure was too small to permit any trend analysis with respect to *radiation* exposures. The SMRs for all cancers and leukemia for male employees and for middle-aged male family members who were not exposed to any *radiation* were not statistically significant. A much larger database of person years at risk would be required to reach definite conclusions. The combined cancer risks for employees and families combined were similar to risks experienced by individuals in Bombay.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Optimal management of borderline epithelial ovarian tumors remains controversial because of the lack of clear, universally accepted pathologic criteria for diagnosis, the lack of complete understanding of the significance of intraperitoneal implants, and the desire to employ more limited surgery in young women. We reviewed the experience with borderline epithelial ovarian tumors at Princess Margaret Hospital in order to assess the natural history of the

disease, to determine prognostic factors that would aid in management decisions, and to determine if adjuvant therapy influenced outcome. Eighty-one patients were analyzed. The mean age was 48 years. Seventy-two percent of tumors were of the serous histologic sub-type and 28% were mucinous. Seventy-eight percent were Stage I, 11% Stage II, and 11% Stage III. Peritoneal washings contained malignant cells in 14 of 32 patients (not recorded or obtained in 49), cyst rupture occurred in 25%, surface excrescences in 40%, and adhesions in 46%. None of these factors had a significant effect on recurrence rate or survival. Eleven patients received adjuvant *radiation* therapy (10 abdomino-pelvic and 1 pelvic alone), four adjuvant chemotherapy, and one both *radiation* therapy and chemotherapy. The rest (65) received no adjuvant therapy. Due to the small numbers and infrequent events, it was not possible to analyze and thus draw valid conclusions regarding the effect of adjuvant therapy on survival or recurrence. The overall survival (OS) and cause specific survival (CSS) were 85% and 96% at 10 years, respectively. No Stage I patient died of tumor. OS for Stage I patients was 90% at 10 years, the majority of whom (61 of 63) received no adjuvant therapy, and is thus unnecessary in Stage I disease. The adequacy of unilateral oophorectomy or ovarian cystectomy could not be confirmed because of small numbers. The 10 year OS and disease-free survival in Stage II and III were 75% and 50%, respectively, despite the use of adjuvant *radiation* therapy, chemotherapy, or both. It is necessary to create a multi-center tumor *registry* in order to acquire a prospective data base from which to develop sound therapeutic decisions. Author-abstract.

TI Cancer mortality after iodine-131 therapy for hyperthyroidism.

SO Int-J-Cancer. 1992 Apr 1. 50(6). P 886-90.

JT INTERNATIONAL JOURNAL OF CANCER.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Cancer mortality was studied in 10,552 Swedish hyperthyroid patients treated with 131I between 1950 and 1975. The patients were matched with the Swedish Cause-of-Death Register and the cases of 977 patients who died from cancer or leukemia were studied. The patients had been followed up for an average of 15 years (range 0 to 35 years), and the overall standardized mortality ratio (SMR) was 1.09 `95% confidence interval (CI) = 1.03 to 1.16:, with a higher risk for women. The highest mortality was seen during the first year after exposure (SMR = 1.15) and decreased for the following 9 years (SMR = 1.04). The risk of dying from a cancer in the digestive tract and respiratory organs was significantly elevated more than 10 years after exposure, as was the overall cancer mortality (SMR = 1.14). No increased risk was seen for leukemia, bladder cancer or breast cancer. Younger patients and those receiving 131I at higher activity had higher SMRs than older patients and those receiving lower activity. Patients with toxic nodular goiter had higher risk than those with Graves' disease. The lack of increasing mortality over time and with increasing activity of 131I administered argues against a carcinogenic effect of 131I. However, in the case of cancers of the stomach, the 131I exposure could have contributed to the excess mortality from these cancers. Author-abstract.

TI Late local complications after definitive radiotherapy for prostatic adenocarcinoma.

SO J-Urol. 1992 Mar. 147(3 Pt 2). P 926-8.

JT JOURNAL OF UROLOGY.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Definitive *radiation* treatment of prostatic adenocarcinoma has been reported to produce good long-term local disease control, and distant disease failure is almost always associated with good local palliation. We examined late local complications in patients who died with recurrent prostate cancer after definitive radiotherapy as compared to patients treated with hormonal deprivation alone for advanced disease. Between 1979 and 1989 the tumor *registry* listed 33 men in whom definitive radiotherapy failed documented by bone scan or biopsy and 54 men who were managed with palliative hormonal therapy for noncurable disease. A complication was defined as a local problem requiring a procedure or hospitalization. Overall 23 of the radiotherapy cases (70%) had a local complication as compared to 16 of the patients (30%) who underwent only hormonal therapy. Local complications after radiotherapy included urethral stricture (10 cases), prostatic obstruction (8), hematuria (4), *radiation* cystitis (3), ureteral obstruction (2) and rectosigmoid *radiation* injury (4). Local complications after hormonal therapy consisted of prostatic obstruction (11 cases), ureteral obstruction (3) and hematuria (3). The radiotherapy group had 2 urinary and 2 fecal diversions, and the hormonal therapy group had none. In summary, we found a higher risk of late local complications in patients who had recurrence and died with metastatic prostate cancer after definitive radiotherapy, as compared to patients who only received hormonal therapy. These results question the belief that patients with distant disease in whom radiotherapy fails enjoy good long-term local palliation.

TI Colorectal cancer and solar *radiation.*

SO Cancer-Causes-Control. 1992 Jan. 3(1). P 95-9.

JT CANCER CAUSES AND CONTROL.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB It has been suggested that sunlight might have a role in the

prevention of colorectal cancer via a mechanism involving vitamin D. We used data from nine population-based cancer *registries* in the United States to analyze incidence rates for colon and rectal cancer during 1973-84 as a function of regional variation in the levels of available solar *radiation.* Data were restricted to include only those persons born and diagnosed in the same state. Incidence rates of colon and rectal cancer among men tended to increase with decreasing levels of solar *radiation.* Compared to rates in New Mexico and Utah, for example, rates in the Detroit area (MI), Connecticut, and western Washington were 50 percent to 80 percent higher. Among women, colon cancer rates showed a similar trend, though of smaller magnitudes; rates of rectal cancer among women did not vary in relation to levels of available solar *radiation.*

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB OBJECTIVE--To study cause specific mortality of *radiation* workers with particular reference to associations between fatal neoplasms and level of exposure to *radiation.* DESIGN--Cohort study.
SETTING--United Kingdom. SUBJECTS--95,217 *radiation* workers at major sites of the nuclear industry. MAIN OUTCOME MEASURE--Cause of death. RESULTS--Most standardised mortality ratios were below 100: 83 unlagged, 85 with a 10 year lag for all causes; 84 unlagged, 86 lagged for all cancers; and 80 for all known other causes, indicating a "healthy worker effect." The deficit of lung cancer (75 unlagged, 76 lagged) was significant at the 0.1% level. Standardised mortality

ratios were significantly raised (214 unlagged, 303 lagged) for thyroid cancer, but there was no evidence for any trend with external recorded *radiation* dose. Dose of external *radiation* and mortality from all cancers were weakly correlated ($p = 0.10$), and multiple myeloma was more strongly correlated ($p = 0.06$); for leukaemia, excluding chronic lymphatic, the trend was significant ($p = 0.03$; all tests one tailed). The central estimates of lifetime risk derived from these data were 10.0% per Sv (90% confidence interval less than 0 to 24%) for all cancers and 0.76% per Sv (0.07 to 2.4%) for leukaemia (excluding chronic lymphatic leukaemia). These are, respectively, 2.5 times and 1.9 times the risk estimates recommended by the International Commission on Radiological Protection, but 90% confidence intervals are large and the commission's risk factors fall well within the range. The positive trend with dose for all cancers, from which the risk estimate was derived, was not significant. The positive association between leukaemia (except chronic lymphatic leukaemia) was significant and robust in subsidiary analyses. This study showed no association between *radiation* exposure and prostatic cancer. CONCLUSION--There is evidence for an association between *radiation* exposure and mortality from cancer, in particular leukaemia (excluding chronic lymphatic leukaemia) and multiple myeloma, although mortality from these diseases in the study population overall was below that in the general population. The central estimates of risk from this study lie above the most recent estimates of the International Commission on Radiological Protection for leukaemia (excluding chronic lymphatic leukaemia) and for all malignancies. However, the commission's risk estimates are well within the 90% confidence intervals from this study. Analysis of combined cohorts of *radiation* workers in the United States indicated lower risk estimates than the commission recommends, and when the American data are combined with our analysis the overall risks are close to those estimated by the commission. This first analysis of the National *Registry* for *Radiation* Workers does not provide sufficient evidence to justify a revision in risk estimates for radiological protection purposes. Author-abstract.

TI Hispanic patients with head and neck cancer do not have a worse
prognosis than Anglo-American patients.
SO Cancer. 1992 Feb 15. 69(4). P 1003-7.
JT CANCER.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB This study was undertaken to determine whether the survival of
Hispanic patients with squamous cell carcinoma of the head and neck
was different from that of Anglo-American patients. The charts of
275 male patients with a diagnosis of squamous cell carcinoma of the
head and neck at one Veterans Administration Hospital were reviewed
in an attempt to identify prognostic indicators for both ethnic
groups. No differences were observed between Anglo-American and
Hispanic patients with respect to sites of the primary tumor, age at
diagnosis, performance status, or the frequency of surgery, *radiation*
therapy, or chemotherapy; however, there was a tendency for Hispanic
patients to have received more treatment. There also was a trend (P
 $= 0.12$) for Hispanic patients to have a more advanced stage of
cancer. Hispanic patients lost significantly more weight (P less
than 0.001) and had significantly lower serum albumin levels (P less
than 0.0001). According to the results of multivariate survival
analyses, the variables that were predictive of a poor prognosis
included advanced stage of disease, decreased serum albumin levels,
increased weight loss, administration of chemotherapy, lack of
radiation therapy or surgery, and advanced age. Ethnicity was not a
significant predictor of survival either in univariate analyses, or
within patients with the same stage of disease, or after adjustment
for other prognostic factors. In conclusion, the natural history of
squamous cell carcinoma of the head and neck is the same for Hispanic
and Anglo-American patients. Author-abstract.

 SO Jpn-J-Ophthalmol. 1991. 35(3). P 292-9.
 JT JAPANESE JOURNAL OF OPHTHALMOLOGY.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB Retrospective studies were made of patients with orbital
 rhabdomyosarcoma (RMS) who were registered in the Japan Children's
 Cancer *Registry* and the National *Registry* of Ocular Tumors in Japan
 during 1974-1989. Thirty-five children under 15 years of age were
 registered as orbital RMS patients. The median age of onset was 5
 years and 2 months; lid swelling was the most frequent initial
 symptom and finding. Histologically, 79% were classified as the
 embryonal type. Orbital exenteration was the standard treatment
 until the mid-1970's, but all the 5 patients who had only surgical
 therapy experienced relapses. Since the mid-1970's, a combined
 regimen of surgery, *radiation* and chemotherapy has been used.
 Chemotherapy has recently been considered to play the most important
 role in this combined therapy. Among the 35 patients studied, three
 patients with only biopsy as the surgical procedure have had no
 relapses up to the present time. Recurrent tumors developed in 15 of
 the remaining 32 patients: 7 of those were local, 8 were distant.
 All relapses (10 of the 14 patients in the 1970's, and 5 of the 18 in
 the 1980's) occurred within 1 year and 11 months after initial
 treatment. The 3-year survival rate of these 32 patients, estimated
 by the Kaplan-Meier method, was 70% (52% in the 1970's, 86% in the
 1980's). Author-abstract.

 JT JOURNAL OF *RADIATION* RESEARCH.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB A tumor *registry* is essential in the systematic collection and analysis of tumor data in a defined population. Population-based tumor *registries* have been in operation for more than 30 years in Hiroshima and Nagasaki. While the tumor *registry* data have previously been used for many site-specific cancer studies in atomic bomb survivors, overall analysis of tumor *registry* based cancer incidence data among the atomic bomb survivors has not been undertaken for some time. However, a recent improvement in the tumor *registries* has made it possible to analyze most recent cancer incidence data among the Life Span Study population. Preliminary analysis under way indicates a potential power of the data. There are a few methodological problems associated with the use of the incidence data, especially relating to consistency of data and migration. Several measures taken to resolve such problems are

discussed. Author-abstract.

TI A health survey of radiologic technologists.

SO Cancer. 1992 Jan 15. 69(2). P 586-98.

JT CANCER.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB A health survey of more than 143,000 radiologic technologists is described. The population was identified from the 1982 computerized files of the American *Registry* of Radiologic Technologists, which was established in 1926. Inactive members were traced to obtain current addresses or death notifications. More than 6000 technologists were reported to have died. For all registrants who were alive when located, a detailed 16-page questionnaire was sent, covering occupational histories, medical conditions, and other personal and lifestyle characteristics. Nonrespondents were contacted by telephone to complete an abbreviated questionnaire. More than 104,000 responses were obtained. The overall response rate was 79%. Most technologists were female (76%), white (93%), and employed for an average of 12 years; 37% attended college, and approximately 50% never smoked cigarettes. *Radiation* exposure information was sought from employer records and commercial dosimetry companies. Technologists employed for the longest times had the highest estimated cumulative exposures, with approximately 9% with exposures greater than 5 cGy. There was a high correlation between cumulative occupational exposure and personal exposure to medical radiographs, related, in part, to the association of both factors with attained age. It is interesting that 10% of all technologists allowed others to practice taking radiographs on them during their training. Nearly 4% of the respondents reported having some type of cancer, mainly of the skin (1517), breast (665), and cervix (726). Prospective surveys will monitor cancer mortality rates through use of the National Death Index and cancer incidence through periodic mailings of questionnaires. This is the only occupational study of *radiation* employees who are primarily women and should provide new information

on the possible risks associated with relatively low levels of exposure. Author-abstract.

LG English (EN).
AB Data for 595 patients with severe aplastic anemia receiving HLA-identical sibling bone marrow transplants were analyzed to determine the effect of pretransplant conditioning and graft-versus-host disease (GVHD) prophylaxis on outcome. Transplants were performed between 1980 and 1987 and reported to the International Bone Marrow Transplant *Registry.* Three conditioning regimens (cyclophosphamide alone, cyclophosphamide plus limited field *radiation,* and cyclophosphamide plus total body *radiation)* were studied; none was associated with superior long-term survival. Three GVHD prophylaxis regimens (methotrexate, cyclosporine, and methotrexate plus cyclosporine) were studied. Recipients of cyclosporine with or without methotrexate had a significantly higher probability of 5-year survival (69%, 95% confidence interval 63% to 74%) than patients receiving methotrexate only (56%, 49% to 62%, P less than .003). Higher survival with cyclosporine resulted from decreased risks of interstitial pneumonia (P less than .0002) and

chronic GVHD (P less than .005). Additional risk factors adversely associated with survival included infection pretransplant (P less than .004), use of parous or transfused female donors (P less than .005), older patient age (P less than .005), and 20 or more pretransplant transfusions (P less than .006). These data may prove useful in planning randomized clinical trials and in identifying patients at high-risk of treatment failure. Author-abstract.

- AB Numerous European cancer *registries* are working together to evaluate the current trends in the incidence of childhood leukemias after the Chernobyl accident. The study is coordinated by the International Agency for Research on Cancer. The primary objective is to establish whether the accident has resulted in an increase in the number of cases. The results will also allow an evaluation of the clusters which could be reported. According to the provisional estimations, the accident could lead to an increase of an average of 0.8% of the frequency of new cases in the European regions covered by the study. For the whole of Switzerland, this increase would correspond to 0.5 supplementary cases per year. Author-abstract.

AB OBJECTIVE--To identify time trends and factors associated with breast-conserving surgery (BCS) and delivery of postoperative *radiation* therapy among women with stage I or II breast cancer. DESIGN--Survey. SETTING--Population-based cancer *registry* in the Seattle-Puget Sound (Wash) region. PARTICIPANTS--The study included 8095 women diagnosed with stage I or II breast cancer (American Joint Committee on Cancer staging criteria) from 1983 through 1989. MAIN OUTCOME MEASURES--Breast-conserving surgery with or without *radiation* therapy vs mastectomy, and, among women with BCS, a comparison of *radiation* therapy vs no therapy. RESULTS--In 1985 when results from a US randomized clinical trial of BCS were published, the frequency of BCS peaked (46.3% of stage I; 30.1% of stage II) followed by a return to levels before 1985 for women with stage II breast cancer and a more moderate decline for stage I breast cancer. The likelihood of BCS decreased with increasing age (P less than .001), with stage II disease, and with residence outside the region's major urban center, and it increased with education (P less than .001) or median income (P less than .001) by census tract. The proportion of women who received *radiation* therapy after BCS decreased with age (P less than .001), was lower for women with stage II than stage I disease, and was lowest in counties without *radiation* therapy facilities. CONCLUSIONS--Despite scientific evidence of the equivalent efficacy of BCS with *radiation* therapy and mastectomy, BCS is not performed on the majority of women with stage I or II breast cancer as recommended by the National Institutes of Health, and factors are associated with its use that differ from selection criteria outlined by the National Institutes of Health. Author-abstract.

AB OBJECTIVE--To determine the degree of compliance with clinical standards among hospitals for care of breast cancer patients and account for variations in compliance. DESIGN--Analysis of cancer *registry* data submitted to the American Cancer Society, Illinois Division, Chicago, for a concurrent prospective descriptive study of breast cancer, supplemented by other hospital data from public sources. SETTING--Ninety-nine Illinois hospitals evenly distributed among rural counties, counties with small cities outside the Chicago metropolitan area, exurban counties in the Chicago metropolitan area, suburban Cook County, and urban Chicago. PATIENTS--A total of 5766 newly diagnosed patients with histologically confirmed breast cancer in 1988, representing 84% of the estimated 6900 new cases in the state for that year. MAIN OUTCOME MEASURES--Descriptive statistics and multiple linear regression analyses of five dependent quality variables from clinical indicators related to early diagnosis, hormone receptor determination, adjuvant therapy, *radiation* therapy, and axillary lymph node dissection. RESULTS--At the hospitals studied, (1) late stage (IIb through IV) at diagnosis was associated with urban location, higher proportion of poorly insured patients, fewer breast cancer cases treated, and lower oncology charges (proportion of variance explained, $R^2 = .50$, P less than .00001); (2) omission of hormone receptor test for stages II through IV was associated with urban location and higher proportion of poorly insured patients ($R^2 = .18$, P less than .00003); and (3) omission of indicated *radiation* therapy was associated with urban location and fewer breast cancer cases ($R^2 = .21$, P less than .00001). Omission of adjuvant therapy and omission of axillary lymph node dissection were not significantly associated with any of the hospital variables examined. CONCLUSIONS--The findings suggest that there is a group of urban hospitals, generally small and marginally reimbursed, where comprehensive diagnosis and treatment of breast cancer are not obtained. TI The adequacy of current occupational standards for protecting the health of nuclear workers.

SO Occup-Med. 1991 Oct-Dec. 6(4). P 725-39.

JT OCCUPATIONAL MEDICINE.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).

LG English (EN).

AB It will be clear from the foregoing that occupational standards have varied over the past 30-40 years since the beginnings of the nuclear industry. Our perception of risk rates for cancer mortality and genetic effects has changed, such that the rates have been constantly revised upwards. Logically, dose limits should have been reduced in proportion, but this assumes a constant approach to the "tolerability" or "acceptability" of risk and this has not been demonstrated. Dose limits are not seen by management in the nuclear industry as the only plank in the structure of *radiation* protection; emphasis is also being given to the "optimization" ethic. In these circumstances a good test of the efficacy of the system of *radiation* control in limiting health effects is needed. As can be seen, no such study is available and, given the doses received and the numbers of workers involved, it is unlikely that any epidemiologic study, apart from studies on miners, will have sufficient statistical power to be totally unequivocal. However, some studies have shown cancer mortality associations with *radiation* exposure that are significant. Probably the best way to mitigate the inherent drawbacks in these studies is to pool data-sets, and this is being done. Other improvements will include estimates of cancer incidence in countries with cancer *registries* (e.g., U.K., Canada, and Sweden) and to perhaps go beyond epidemiologic data to consider sensitive biologic markers as indices of exposure. Overall the conclusion must be that the *radiation* industry cannot be complacent and for some tasks in the processes involved (e.g., uranium mining) there is strong evidence of a history of unacceptable health effects occurring.

AB Forty-two of 416 familial adenomatous polyposis (FAP) patients in the
FAP *registry* at the Cleveland Clinic had desmoid tumors. The role of
cytotoxic chemotherapy and *radiation* therapy in the management of
these patients was investigated. Eight intra-abdominal desmoid
tumors were treated by systemic cytotoxic chemotherapy. Two had
complete remission, and one had partial remission. Five patients
died as a result of the desmoid tumor or late complications of
chemotherapy. Three intra-abdominal desmoids were treated by
radiation therapy with no response. Neither cytotoxic chemotherapy
nor *radiation* therapy is recommended as a first-choice treatment for
intra-abdominal desmoid tumors in patients with FAP.

TI Recent trends in the incidence of salivary gland cancer.

SO Int-J-Epidemiol. 1991 Sep. 20(3). P 628-33.

JT INTERNATIONAL JOURNAL OF EPIDEMIOLOGY.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Beginning in 1985, a sudden and sustained doubling of salivary gland cancer incidence, among men only, is observed in the San Francisco-Oakland Metropolitan Statistical Area. *Registry* data are examined to determine the nature of this increase and its possible association with the AIDS epidemic. Changes in patient characteristics are assessed by comparing their distribution among recently diagnosed cases (1985-1988) to an expectation based on population growth and the age-specific incidence among patients diagnosed earlier (1973-1984). Based on the observed patterns, it is unlikely that the temporal increase in these tumours is a direct result of the AIDS epidemic or solely the result of a shift in the prevalence of established risk factors. The increase is predominantly seen in men over the age of 75 at diagnosis (O/E = 2.3, $p = 0.02$) and is observed among both those with and without a prior cancer (O/E = 2.7, $p = 0.02$ and O/E = 1.5, $p = 0.06$, respectively). *Radiation* for the prior cancer was not associated with increased occurrence. Military exposure is crudely approximated by examining birth cohorts. However, the cohort data do not support a hypothesis of military exposure. Author-abstract.

SO Mutagenesis. 1991 Jul. 6(4). P 285-8.

JT MUTAGENESIS.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB The genetic consequences of radioactive fall-out deposition from the Chernobyl (USSR) accident in Hungary was evaluated as a part of the ongoing programme on the population-based Hungarian Surveillance of Germinal Mutations. The surveillance is based on three groups of indicator conditions: 15 sentinel anomalies (indicators of germinal dominant gene mutations), Down's syndrome (an indicator of germinal numerical and structural chromosomal mutations) and unidentified multiple congenital abnormalities (indicators of germinal dominant gene and chromosomal mutations). Cases with these indicator conditions were selected from the material of the Hungarian Congenital Abnormality *Registry.* After the diagnostic accuracies were checked, familial and sporadic cases were separated. Only the latter group was evaluated for evidence of new mutations. The analysis did not reveal any measurable germinal mutagenic effects of the Chernobyl accident. Furthermore, there were no significant differences in the rates of these three groups of indicator conditions between regions with higher and lower increased background *radiation.* Author-abstract.

 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB A retrospective study of survival results for pancreatic cancer was
 performed. The study had two objectives: 1) to relate the extent of
 disease and management to survival, and 2) to determine whether newer

treatment combinations have altered prognosis. Cancer registrars from 88 Illinois hospitals reviewed original medical records and submitted standardized report forms on 2,401 patients diagnosed between 1978-84. Three-year survival time was longer after laparotomy/bypass plus *radiation/chemotherapy* than for laparotomy/bypass alone (P less than .02). But the difference in survival between resection versus resection, *radiation,* and chemotherapy was not significant (P = .16). After resection, the median survival for 78 Stage I patients was 12.5 months, whereas for 181 Stage I patients after laparotomy/bypass it was 6.8 months (P less than .00001). For patients without metastases, 3-year survival was significantly better for 249 patients in whom cancer was resected versus 568 unresected patients (P less than .001). Survival was longer for 568 unresected patients without gross metastases than for 954 patients with metastatic disease found at laparotomy (P less than .05). From this study the authors concluded that: 1) since 3-year survival results were higher than expected after resection for localized cancers, resection is still desirable when it can be done with acceptable complication risks, and 2) the use of multiple treatment modalities for pancreatic cancer warrants further study in organized trials. Author-abstract.

AB Pregnancy outcome has been studied in terms of legal abortions, early spontaneous abortions and total number of pregnancies (in an ad hoc study covering 6 counties) as well as various perinatal health problems (on the basis of routinely recorded data for epidemiological surveillance from the Medical Birth *Registry* of Norway). Apparently, no effects were observed in terms of an increased occurrence of legal abortions, while spontaneous abortions increased from 7.2% of all pregnancies during the last 12 months before the accident to 8.3%

after the accident `corrected:'. At the same time, the total number of pregnancies somewhat decreased. Based on monthly measurements in each municipality of external and internal (food-based) doses, dose-response associations were assessed for a number of perinatal health problems. No associations were observed. Author-abstract.

JT JPEN. JOURNAL OF PARENTERAL AND ENTERAL NUTRITION.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB The OASIS *Registry* started annual collection of longitudinal data on patients on home parenteral nutrition (HPN) in 1984. This report describes outcome profiles on 1594 HPN patients in seven disease categories. Analysis showed clinical outcome was principally a reflection of the underlying diagnosis. Patients with Crohn's disease, ischemic bowel disease, motility disorders, *radiation* enteritis, and congenital bowel dysfunction all had a fairly long-term clinical outcome, whereas those with active cancer and acquired immunodeficiency syndrome (AIDS) had a short-term outcome. The long-term group had a 3-year survival rate of 65 to 80%, they averaged 2.6 complications requiring hospitalization per year, and 49% experienced complete rehabilitation. The short-term group had a mean survival of 6 months; they averaged 4.6 complications per year and about 15% experienced complete rehabilitation. The *registry* data also indicated HPN was used for 19,700 patients in 1987 with therapy growth averaging about 8% per year. This growth was chiefly from new cancer patients. The number of new patients with long-term disorders in whom HPN was initiated appeared rather constant. We conclude that

these clinical outcome assessments justify HPN for long-term patients, but the utility and appropriateness of HPN for the cancer and AIDS patients remains uncertain and requires further study. Medical, social, and fiscal aspects of HPN management in long-term and short-term patients appear to involve quite separate considerations. Author-abstract.

JT CANADIAN ASSOCIATION OF RADIOLOGISTS JOURNAL.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Individual and collective *radiation* doses received by Canadian
radiation technologists (RTs) working in diagnostic radiology,
nuclear medicine and radiotherapy are summarized for the period 1978
to 1988. The data were obtained directly from the National Dose
Registry, Department of National Health and Welfare. Over the
11-year study period the mean annual dose equivalent fluctuated
around 0.2, 1.8 and 1.1 mSv for RTs working in diagnostic radiology,
nuclear medicine and radiotherapy respectively. Over the same period
the occupational collective dose equivalent decreased in diagnostic
radiology (by 44%) and radiotherapy (by 35%) and increased in nuclear
medicine (by 45%). Approximately 10,000 RTs are monitored each year,
with an estimated total occupational collective dose equivalent of
about 3.6 person-sieverts. Analysis of dose distribution data showed
that only 1.3% of all monitored RTs received an annual whole-body
dose equivalent greater than the current legal limit for members of
the public (5 mSv). Approximately half of the RTs working in nuclear
medicine and radiotherapy received an annual dose equivalent in
excess of 0.5 mSv; only 7.3% of their diagnostic radiology
counterparts exceeded this level. Demographic data showed a high
preponderance of young women in all three RT classifications, and an
analysis of the *radiation* risks to this occupational group revealed
increases of up to 12% above the risk associated with a "standard"
adult working population exposed to the same collective dose
equivalent. Author-abstract.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Management of minor salivary gland adenoid cystic carcinoma is a controversial problem. Few clinicians obtain adequate experience in the treatment of this disease, which is often frustrated by early and late distant metastases. Fourteen cases of minor salivary gland adenoid cystic carcinoma recorded in the Delaware *Registry* over a 20-year period (1968 to 1988) were reviewed retrospectively. These cases were evaluated for their duration of symptoms; size, location, and histologic subtype of the lesion; perineural invasion; lymph node metastases; and treatment to determine the relationship of these factors to survival. Location and histologic subtype of the lesion and duration of symptoms were found to have a more significant impact on survival than size of the lesion, perineural invasion, or lymph node metastases. Surgery is the mainstay of therapy for minor salivary gland adenoid cystic carcinoma, with resection that includes disease-free margins but spares function being advocated. Although adjunctive *radiation* therapy has not been shown to increase survival, it is reasonable in lesions with perineural invasion and/or lymph node metastases. Author-abstract.

 AB A retrospective review of the Memorial Sloan Kettering Cancer Center experience (MSKCC) with esthesioneuroblastoma was performed. From 1975 to 1985 14 cases were identified. Overall 5- and 10-year survival was 86% and 70%, respectively. Four local failures were observed and 4 neck failures were observed. A review of the literature since 1966 revealed an unexpectedly high incidence of neck failure, and of the 21 of 110 patients with neck failures that were identified through the literature, there were 6 subsequent deaths.  TI Cancer risks in thyroid cancer patients.
 SO Br-J-Cancer. 1991 Jul. 64(1). P 159-63.
 JT BRITISH JOURNAL OF CANCER.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB Cancer risks were studied in 834 thyroid cancer patients given 131I (4,551 MBq, average) and in 1,121 patients treated by other means in Sweden between 1950 and 1975. Record-linkage with the Swedish Cancer Register identified 99 new cancers more than 2 years after 131I therapy `standardised incidence ratio (SIR) = 1.43; 95% confidence interval (CI) 1.17-1.75: vs 122 (SIR = 1.19; 95% CI 0.88-1.42) in patients not receiving 131I. In females treated with 131I overall SIR was 1.45 (95% CI 1.14-1.83) and significantly elevated were noted for tumours of the salivary glands, genital organs, kidney and adrenal gland. No elevated risk of a subsequent breast cancer or leukaemia was noted. SIR did not change over time, arguing against

a strong *radiation* effect of ¹³¹I. Organs that were estimated to have received more than 1.0 Gy had together a significantly increased risk of a subsequent cancer following ¹³¹I treatment (SIR = 2.59; n = 18). A significant trend was seen for increasing activities of ¹³¹I with highest risk for patients exposed to greater than or equal to 3,664 MBq (SIR = 1.80; 95% CI 1.20-2.58). No specific cancer or group of cancers could be convincingly linked to high-dose ¹³¹I exposures since SIR did not increase after 10 years of observation. However, upper confidence intervals could not exclude levels of risk that would be predicted based on data from the study of atomic bomb survivors. We conclude that the current practice of extrapolating the effects of high-dose exposures to lower-dose situations is unlikely to seriously underestimate *radiation* hazards for low LET *radiation.* Author-abstract.

TI Incidence of new primary cancers after adjuvant tamoxifen therapy and radiotherapy for early breast cancer.

SO J-Natl-Cancer-Inst. 1991 Jul 17. 83(14). P 1013-7.

JT JOURNAL OF THE NATIONAL CANCER INSTITUTE.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB The incidence of new primary cancers was evaluated in 3538 postmenopausal patients who had received surgical treatment for primary breast cancer. Of these patients, 1828 with a low risk of recurrence received no further treatment. High-risk patients were randomly assigned to one of two groups. The first group (n = 846) received postoperative radiotherapy, while the second group (n = 864) received radiotherapy plus tamoxifen at a dose of 30 mg given daily for 48 weeks. The median observation time was 7.9 years. In comparison with the number of new cancers in the general population, the number of new cancers in the three groups was elevated mostly due

to a high number of cancers of the contralateral breast and of colorectal cancers in the high-risk groups. The cumulative risk of nonlymphatic leukemia was increased among patients who received postoperative radiotherapy ($P = .04$). Cancer incidence in the high-risk tamoxifen-treated group relative to that in the high-risk group not treated with tamoxifen was not significant (1.3). No protective effect of tamoxifen on the opposite breast was seen (rate ratio for breast cancer = 1.1), but a tendency to an elevated risk of endometrial cancer was observed (rate ratio = 3.3; 95% confidence interval = 0.6-32.4). Continued and careful follow-up of women treated with tamoxifen is necessary to clarify the potential cancer-suppressive or cancer-promoting effects of this drug.

TI Maternal and perinatal risk factors for childhood leukemia.
SO Cancer-Res. 1991 Jul 15. 51(14). P 3696-701.
JT CANCER RESEARCH.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB This report describes an exploratory population-based study of maternal and perinatal risk factors for childhood leukemia in Sweden. The Swedish National Cancer *Registry* ascertained 411 cases in successive birth cohorts from 1973 through 1984 recorded in the Swedish Medical Birth *Registry.* Using the latter, we matched five controls without cancer to each case by sex and month and year of birth. Mothers of children with leukemia were more likely to have been exposed to nitrous oxide anesthesia during delivery than mothers of controls `odds ratio (OR) = 1.3; 95% confidence interval (CI) = 1.0, 1.6:. Children with leukemia were more likely than controls to have Down's syndrome (OR = 32.5; 95% CI = 7.3, 144.0) or cleft lip or cleft palate (OR = 5.0; 95% CI = 1.0, 24.8); to have had a diagnosis

associated with difficult labor but unspecified complications (OR = 4.5; 95% CI = 1.1, 18.2) or with other conditions of the fetus or newborn (OR = 1.5; 95% CI = 1.1, 2.1), specifically, uncomplicated physiological jaundice (OR = 1.9; 95% CI = 1.2, 2.9); or to have received supplemental oxygen (OR = 2.6; 95% CI = 1.3, 4.9). Because multiple potential risk factors were analyzed in this study, future studies need to check these findings. We did not confirm the previously reported higher risks for childhood leukemia associated with being male, having a high birth weight, or being born to a woman of advanced maternal age. TI Postirradiation sarcoma. Analysis of a nationwide cancer *registry* material.

SO Cancer. 1991 Aug 1. 68(3). P 524-31.

JT CANCER.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Thirty-three cases of postirradiation sarcoma (PIS) from the files of the Finnish Cancer *Registry* were analyzed. The most frequent first primary tumors were cancers of the breast (seven cases) and female reproductive organs (13 cases). Five patients had a childhood cancer. The median total *radiation* dose at the site of the PIS was 3600 cGy (1600 cGy to 11200 cGy). The median interval from start of *radiation* therapy to detection of PIS was 13.2 years (3.4 to 22.8 years). The PIS was of soft tissue origin in 25 of 33 cases. The most frequent histologic types were osteosarcoma (ten cases, including four extraskkeletal tumors), malignant fibrous histiocytoma (ten cases), and fibrosarcoma (six cases). The overall crude 5-year survival rate was 29% (calculated from the start of treatment for PIS), and for patients initially treated with either radical surgery

or combined marginal surgery and postoperative irradiation it was 67%. The authors conclude that there is a chance for cure for radically treated patients with postirradiation sarcoma that emphasizes the importance of regular long-term follow-up of cancer patients. Author-abstract.

AB There is concern about the long-term carcinogenic effects of psoralen and ultraviolet A *radiation* (PUVA) therapy for treatment of skin disorders. A study of 4799 Swedish patients (2343 males, 2056 females; mean age at first treatment 45.3 years, range 6-93; mean follow-up 6.9 years males, 7.2 years females) who received PUVA between 1974 and 1985 showed a dose-dependent increase in the risk of squamous cell cancer of the skin. Male patients who had received more than 200 treatments had over 30 times the incidence of squamous cell cancer found in the general population. Significant increases (p less than 0.05) were also found in the incidences of respiratory cancer in males and females, pancreatic cancer in males, and kidney and colonic cancer in females. This study confirms previous reports of a dose-dependent increase in the incidence of squamous cell cancer in patients treated with PUVA. Author-abstract.

 LG English (EN).
 AB Between 1954 and 1983, 7620 patients were treated for breast
 carcinoma at Institut Gustave Roussy (France). Of these patients,
 6919 were followed for at least 1 year. Out of these, 11 presented
 with sarcomas thought to be induced by irradiation, 2 of which were
 Stewart-Treves Syndrome, and 9 of which were sarcomas within the
 irradiated fields. All histological slides were reviewed and a
 comparison with those of breast cancer was done. The sites of these
 sarcomas were: parietal wall, 1 case; second costal cartilage, 1
 case; infraclavicular region, 1 case; supraclavicular region, 2
 cases; internal third of the clavicle, 2 cases; axillary region 2
 cases; and the internal side of the upper arm (Stewart-Treves
 syndrome), 2 cases. The median age of these 11 patients at the
 diagnosis of sarcomas was 65.8 (49-83). The mean latent period was
 9.5 years (4-24). Three patients underwent radical mastectomy and
 nine modified radical mastectomy. Only one patient received
 chemotherapy. The *radiation* doses received at the site of the
 sarcoma were 45 Gy/18 fr. for 10 cases and 90-100 Gy for 1 case (due
 to overlapping between two fields). The histology was as follows:
 malignant fibrous histiocytoma, 5 cases; fibrosarcoma, 3 cases;
 lymphangiosarcoma, 2 cases; and osteochondrosarcoma, 1 case. The
 median survival following diagnosis of sarcoma was 2.4 years (4
 months-9 years). Two patients are still alive: one with recurrence

of her breast cancer, the other in complete remission, with 7 and 3 years follow-up, respectively. All other patients died from their sarcomas. The cumulative incidence of sarcoma following irradiation of breast cancer was 0.2% (0.09-0.47) at 10 years. The standardized incidence ratio (SIR) of sarcoma (observed n# of cases (Obs)/expected n# of cases (Exp) computed from the Danish Cancer *Registry* for the same period) was 1.81 (CI 0.91-3.23). This is significantly higher than one, with a $p = 0.03$ (One Tailed Exact Test). The mean annual excess (Obs-Exp)/100.000 person-years at risk during the same period/(100,000) was 9.92. This study suggests that patients treated by *radiation* for breast cancer have a risk of subsequent sarcomas that is higher than the general population. However, the benefit from adjuvant *radiation* therapy in the treatment of breast cancer exceeds the risk of second cancer; therefore, the potential of *radiation-induced* sarcomas should not be a factor in the selection of treatment for patients with breast cancer. AB In comparison with the general Danish population, the relative risk (RR) for cancer among staff members employed in two radiotherapy departments in Denmark during 1954-1982 and alive on 1 April 1968 was assessed by linkage to the Danish Cancer *Registry.* All staff had been monitored with film dosimeters for exposure to *radiation.* The study cohort consisted of 4151 persons, accruing 49553 person-years at risk. The collective *radiation* dose was 76.54 manSv and the mean

dose 18.4 mSv. A total of 163 cancer cases were observed with 152.3 expected. The risks for cancers usually considered to be radiogenic were not elevated. A significant excess of prostatic cancer was observed (five cases, relative risk, 6.02; 95% confidence interval, 1.94-14.06); this is likely to be a chance finding. No relation was observed between *radiation* dose or years of exposure and cancer risk, but a weak non-significant increase in risk with time since first exposure was seen. Author-abstract.

AB The carcinogenic effects of ionizing *radiation* at high doses are un
questionable. On the other hand, the deleterious exposure effects to
low doses have not been totally proven, mainly due to methodological
problems and difficulty in measuring reliable dose exposure. In this
paper, some recent studies examining the effects of ionizing
radiation in some occupational groups are reviewed and discussed.
Also, the main areas of epidemiologic controversy are stressed. For
future experiences, prospective, longitudinal studies with
occupational cohorts, measuring *radiation* exposure with adequate
registry and follow-up, are suggested. Author-abstract. 20 Refs.

AB From 1968-1985 a series of thirty-seven patients with primary hepatocellular carcinoma was collected from the tumor *registry* of the Fairfax County Hospital, in the metropolitan Washington, D.C. area. These patients were found to have a mean age at diagnosis of sixty-two (males) to sixty-six (females). Thirty per cent of patients were previously cirrhotic and nineteen per cent had a history of viral hepatitis. There were no patients with documented birth control pill or steroid use. The most common presenting symptoms were anorexia and right upper quadrant pain. Liver-spleen

scan was the most commonly used diagnostic study, but by the 1980's CT scanning was usually diagnostic. Both alkaline phosphatase and serum glutamyltransferase were reliably elevated in twenty-six of twenty-eight and twenty-one of twenty-four patients respectively. Forty-eight per cent of patients with tumor histology reported had multicentric tumors, thirty-eight per cent had nodular tumors, and fourteen per cent had diffuse disease. Survival was as dismal in this as in other studies with a mean of seventy-nine days. No significant difference was noted between cirrhotic and non-cirrhotic patients. Chemotherapy and *radiation* therapy did not significantly impact upon survival. Finally, a cohort analysis was done and a possibly significant peak in incidence of primary hepatocellular carcinoma was seen in men born from about 1911 through 1920. The authors noted that these males were in the group of draft eligible persons for World War II and questioned a link between veteran status and later development of HCC. Author-abstract.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB To investigate the effect of age on treatment choice and survival in patients with breast cancer, data from the cancer *registry* of the Netherlands Cancer Institute (NKI, Amsterdam, The Netherlands) on 611 women have been analyzed. All patients 55 years and older admitted to the NKI for primary treatment of breast cancer between 1981 and 1986 were selected. For women 75 years and older, physicians were less likely to use treatment of adjuvant *radiation* therapy after a mastectomy and more often employed primary hormonal therapy only for local stage disease than for younger patients. Life-table analysis showed that disease-specific survival at 7 years for patients 65 through 74 years of age was significantly better (65%) than that of

the youngest (55%) and the oldest age group (50%). In multivariate regression analysis (Cox), age older than 74 years was significantly and independently associated with a shorter disease-specific survival as compared with patients younger than 75 years. This difference in survival, however, does not seem to be the result of the difference in treatment between the age groups, but suggests an influence of age-related factors such as comorbid diseases and weak physical condition, which manifest themselves most strongly in the oldest age category and make the older woman more vulnerable to the course of malignant disease. Author-abstract.

AB Apart from choriocarcinoma, involvement of the central nervous system (CNS) by gynecologic malignancy is rare. A 10-year retrospective review at the University of Washington Medical Center (Seattle, WA) and Swedish Hospital and Medical Center Tumor *Registry* (Seattle, WA) identified 14 patients with cerebral metastases from ovarian carcinoma. Median age at diagnosis of cerebral metastases was 52.5 years. Median interval from the diagnosis of ovarian carcinoma to the diagnosis of CNS metastases was 14.5 months. Seven patients had received cisplatin therapy before CNS relapse. Seven patients underwent second-look procedures before developing CNS metastases; in three, results were negative. Eight patients had evidence of extraperitoneal spread to other sites at the time of CNS relapse. Clinical manifestations included motor weakness, seizures, headache, confusion, and speech disturbance. All lesions were contrast enhancing on computed tomography (CT) scans and were located in the cerebral hemispheres. Nine patients had single lesions, five of whom underwent surgical resection of the lesion with histologic

confirmation of metastases from the primary site. Median survival was 2 months in patients receiving *radiation* therapy alone and 17 months in patients who received surgery and *radiation.* Median survival of the entire series was 3 months. The presence of multiple cerebral metastases or evidence of extraperitoneal spread elsewhere in the body was adversely associated with survival. The prognosis of patients with cerebral metastases from ovarian carcinoma appears poor. However, early diagnosis by routine CT scanning followed by surgical resection and *radiation* may improve overall survival in a select group of patients. Author-abstract.

AB Neoplasia may develop in patients with malignant hematologic disorders, during remission after radio and/or chemotherapy. A multifactorial origin related to therapy may be postulated. From 1978 to 1987, among 142 patients with malignant hematologic disorders (Hodgkin lymphoma 33, non-Hodgkin lymphoma 51, Multiple Myeloma 35 and Chronic Myeloid Leukemia 31) we observed 3 patients developing another neoplasia. An additional patient with acute non-lymphatic leukemia had been submitted to chemotherapy for gastric cancer. Four

other patients with double neoplasia, one of them a hematologic one, had not been submitted to chemotherapy. The lack of national *registries* for neoplastic diseases precludes an estimation of the odd ratios involved in our findings. Author-abstract.

AB *Radiation* exposures to the scalp during childhood for tinea capitis were associated with a fourfold increase in skin cancer, primarily basal cell carcinomas, and a threefold increase in benign skin tumors. Malignant melanoma, however, was not significantly elevated. Overall, 80 neoplasms were identified from an extensive search of the pathology logs of all major hospitals in Israel and computer linkage with the national cancer *registry.* *Radiation* dose to the scalp was computed for over 10,000 persons irradiated for ringworm (mean 7 Gy), and incidence rates were contrasted with those observed in 16,000 matched comparison subjects. The relative risk of radiogenic skin cancer did not differ significantly between men or women or by time since exposure; however, risk was greatest following exposures in early childhood. After adjusting for sex, ethnic origin, and attained age, the estimated excess relative risk was 0.7 per Gy and the average excess risk over the current follow-up was 0.31/10(4) PY-Gy. The risk per Gy of *radiation-induced* skin cancer was intermediate between the high risk found among whites and no risk found among blacks in a similar study conducted in New York City (Shore et al., Radiat. Res. 100, 192-204, 1984). This finding suggests the role that subsequent exposure to uv *radiation* likely plays in the expression of a potential *radiation-induced* skin

malignancy. Author-abstract.

AB In this paper we combine Japanese data on *radiation* exposure and cancer mortality with U.S. data on cancer incidence and lethality to estimate the effects of ionizing *radiation* on cancer incidence. The analysis is based on the mathematical relationship between the mortality rate and the incidence and lethality rates, as well as on statistical models that relate Japanese incidence rates to U.S. incidence rates and *radiation* risk factors. Our approach assumes that the risk of death from causes other than the cancer does not depend on whether or not the cancer is present, and among individuals with the cancer, the risk of death attributable to the cancer is the same in Japan and the U.S. and is not affected by *radiation* exposure. In particular, we focus on the incidence of breast cancer in Japanese women and how this incidence is affected by *radiation* risk factors. The analysis uses Japanese exposure and mortality data from the *Radiation* Effects Research Foundation study of atomic bomb survivors and U.S. incidence and lethality data from the Surveillance, Epidemiology, and End Results *Registry.* Even without Japanese incidence data, we obtain reasonable estimates of the incidence of breast cancer in unexposed Japanese women and identify the *radiation* risk factors that affect this incidence. Our analysis demonstrates that the age at exposure is an important risk factor, but that the incidence of breast cancer is not affected by the city of residence (Nagasaki versus Hiroshima) or the time since exposure. AB Non-melanoma skin cancer (NMSC) is rarely recorded in cancer *registries* and it is only relatively recently that the serious public health implications, especially in terms of morbidity and expense, have been appreciated. Increased recreational sun exposure (particularly among the young) and ozone layer depletion have generated concern in many countries. Histological confirmation of the diagnosis, either by excision biopsy or punch biopsy is essential if management of the condition is to be rational and the results assessed. Surgery or radiotherapy or other dermatological techniques will cure over 90% of all NMSC. Comparison of the results of various modalities is difficult and poorly documented. Local recurrence rates of 2.0% for surgery and 3.7% for superficial X-ray treatment (SXRT), with 96% and 90% 5-year failure-free-survival respectively are reported from the Peter MacCallum Cancer Institute. More comparative trials are required with good cosmetic and late normal tissue damage evaluation. Factors affecting modality choice trends in Australia are discussed, where the role of plastic surgery has considerably expanded. The indications for radiotherapy and its fractionation require clarification, as does the use of moulds and implants. The belief that solar keratoses transform to invasive cancer has been seriously brought into question by recent Australian epidemiological studies. There can, however, be little doubt of the fact that keratoses are markers of cumulative solar damage, which is a well recognised risk factor for development of NMSC. There is a move away from aggressive ablative treatment of keratoses. The management of keratoacanthoma (KA) by observation is the usual practice, although radiotherapy is occasionally used when the lesion is conspicuous and unsightly.(ABSTRACT TRUNCATED AT 250 WORDS).

 AB High rates of leukaemia in children and young people have been associated with features of community isolation and population growth. Incidence data collected by two specialist *registries* were used to compare incidence rates at ward level with relevant ward characteristics derived from routine census and Ordnance Survey data for England and Wales. An excess risk of childhood acute lymphoblastic leukaemia (ALL) was found for wards which are farthest from large urban centres. The excess was greatest for wards of higher socioeconomic status and for children aged 1-7 years (the childhood peak), for which a two-fold excess was seen. These findings in general support the hypothesis that childhood leukaemia has an infectious aetiology. Author-abstract.

 AB Clear and complete documentation of the physical parameters of total

body irradiation (TBI) is one of the essential requirements for the evaluation and improvement of the clinical results of TBI. Concerning the dosimetric aspects of TBI, a number of recommendations have been formulated with emphasis on basic dosimetry, patient dosimetry and dose specification. The dosimeters should be calibrated regularly with reference to the absorbed dose in water. Depth dose measurements should be performed in water equivalent phantoms of specified dimensions. It has been strongly suggested to measure the absorbed dose at the surface of the patient at 8 different regions at the entry and exit of the beam under TBI conditions. The reference dose to the patient should be specified as the total dose to mid abdomen at the height of the umbilicus. As an independent parameter, the lung dose should be specified as the mean dose in the central region of the shielded part of both lungs. Recent, more complete, information on the physical and dosimetric aspects of TBI will be incorporated in the *registry* of the European Bone Marrow Transplant Group (EBMT). A cooperation has been established between the EBMT and the European Late Effects Project Group (EULEP) to study the development of late effects in man caused by ionising *radiation.* Author-abstract.

AB As the treatment of childhood cancer continues to improve, the number of survivors at risk for late effects rises. One such late effect is the risk of second malignant neoplasms. Large multicenter *registries* have been established to accumulate data on the incidence of second cancers. Relative risks and cumulative risks can now be calculated for retinoblastoma, Wilm's tumor and Hodgkin's disease. Early data are now available for leukemia, sarcomas and central nervous system tumors. Genetic cancer syndromes, *radiation* therapy and treatment with chemotherapeutic agents are known risk factors for second malignant neoplasms in survivors of childhood cancer. AB A review of all primary cardiac tumors seen at the University of
Minnesota or entered in the *Registry* of Cardiovascular Disease,
affiliated with the University of Minnesota, between 1959 and 1989.
Of a total of 124 primary cardiac tumors, 103 (83%) were benign and
21 (17%) were malignant. Atrial myxomas (51 cases) accounted for 42%
of all tumors and 50% of benign neoplasias. The remaining 51 benign
tumors were, in order of frequency: rhabdomyomas, 14 (13%),
papillomas, 12 (11%), fibromas, 9 (9%), hamartomas, (4%), teratomas
(2%), lipomas (2%), mesotheliomas (2%), fibroelastomas, hemangiomas,
glomangiomas, and a few others. The 21 malignant tumors, all
sarcomas, were, in order of frequency: rhabdomyosarcomas, 6 (29%),
angiosarcomas, 4 (19%), myxosarcomas, 3 (14%), fibrosarcomas, 2
(10%), and one each leiomyosarcoma, reticulum cell sarcoma, and
liposarcoma. There were 3 cases of spindle cell sarcoma (14%)
originating in the great vessels: 1 in the pulmonary artery and 2 in
the aorta. The prognosis of the resected benign tumors was good,
with no complications of recurrences for up to 15 years of follow-up.
Tumors that could not be excised included mostly rhabdomyomas, in
newborns, and cavernous hemangiomas involving most of the heart, with
poor prognosis. Malignant tumors of the heart had a very poor
prognosis, even when operated on promptly after diagnosis. The mean
survival time of these patients was 5 months after resection, even
when followed with chemotherapy and/or *radiation;* 26% of the tumors
had already metastasized at the time of operation. Extensive
resections in malignant tumors did not render satisfactory results.

cases in South Dakota for the years 1983 and 1988. There were 225
cases in the 1983 group and 266 cases in the 1988 group. Data from
this project revealed over 16% of patients in both groups had
positive family histories for breast cancer. More cases in 1988
(119) were Stage I as compared to 1983 (69) suggesting earlier
detection through increased awareness of the dangers of this disease
by improved educational programs from 1983 to 1988, and the increased
use of mammography in 1988 (86.8% of patients) as compared to 1983
(48% of patients). Modified radical mastectomy was the initial
therapy in the majority of cases in both groups. Segmental resection
followed by *radiation* therapy was the initial local therapy for 13
patients in 1988 as compared to six patients in 1983. Hormone
receptor analysis was obtained in over 70% of patients in both
groups. Adjuvant drug therapy was given to 25% of patients in both
groups. Only two patients in 1983 and one patient in 1988 were
entered on national research protocols. Author-abstract.

 AB The importance of a uniform coding system for cancer research, tumor
 registry, and exchange of information is recognized. However, tumors
 arising in children differ from those in adults, resulting in lack of
 precision when one coding system is used for both. Because the
 topographic code of the International Classification of Disease for
 Oncology for adult tumors does not lend itself well to pediatric
 tumors, the International Society of Paediatric Oncology (SIOP)
 developed a four-digit topographic coding system particularly adapted
 to childhood tumors. The four digits correspond to anatomic site,
 general and specific localization, and tissue of origin. An SIOP
 pilot study demonstrated the usefulness of this code.

 AB Since 1975, the American Cancer Society, Illinois Division, has
 published end results of major cancer sites drawn from patient data
 contributed voluntarily by hospital cancer *registries* throughout the
 state. The current study was undertaken, in part, to apprehend
 information regarding contested areas in the management of patients
 having differentiated (papillary/follicular) thyroid cancer. A total
 of 2,282 patients with either papillary or follicular carcinoma of
 the thyroid from 76 different Illinois hospitals and providing 10

years of follow-up information (life-table analysis) were retrospectively analyzed for demographic, disease, and treatment-related predictors of survival. Multivariate analysis using the Cox proportional hazards method was made for stage, age, race, sex, morphology, history of *radiation* exposure, presence of positive lymph nodes, initial surgical treatment, postoperative iodine 131 therapy, and replacement/suppressive thyroid hormone treatment. Statistically significant (p less than or equal to 0.05) predictors of favorable survival after thyroid cancer were low stage (I and II), young age (less than 50 years), white race, female sex, and the administration, postoperatively, of either thyroid hormone or radioactive iodine. Factors that had no influence on survival were lymph node status, choice of initial surgical treatment, and a history of prior irradiation. We suggest that where a prospective clinical trial is impracticable, a retrospective analysis of a large and detailed database, such as that available from cooperating hospital-based tumor *registries,* may yet provide useful insights to solutions of cancer management problems. PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB External gamma-ray exposures from fallout originating at the Nevada
Test Site (NTS) have been assigned to 6,507 individual subjects
(1,177 leukemia cases and 5,330 control subjects) who died as Utah
residents between 1952 and 1981. Leukemia cases were identified,
confirmed, and classified by cell type from the Utah Cancer *Registry,*
Utah State vital records, and medical records. Residential histories
were obtained from the Deceased Membership File (DMF) of the Church
of Jesus Christ of Latter-day Saints (LDS), supplemented by
information from the LDS Church Census Records that were taken in
1950, 1955, and 1960-62. Control subjects were selected randomly
within age strata from the DMF and were frequency-matched to the
cases by age at death and for sex. Individual *radiation* exposures
were assigned as a function of residence location and time interval
for each residence during the fallout period (1951-1958) using
geographic exposure data taken from the literature. Temporal
distribution of exposure for subjects who resided in more than one
locality or who were born or died during the fallout period was
determined from data of other investigators. Calculated gamma-ray
exposures for each place of residence were summed for each subject to
yield the exposure to fallout from the NTS. Author-abstract.

LG German (GE).

AB In 4468 patients diagnosed with invasive cancer or carcinoma in situ of the uterine cervix in Saarland/W-Germany in 1968-1987, 149 secondary cancers were observed compared to 150.6 which would have been expected had the same risk prevailed as in the general population (SMR = 0.99, 95% confidence interval 0.84-1.17). There were, however, substantial differences between the relative risks for specific cancer sites. For example, the risk of breast cancer was clearly lower than in the general population (SMR = 0.62, 95% confidence interval 0.43-0.88), while the risk of cancer of the urinary bladder was significantly increased (SMR = 2.88, 95% confidence interval 1.53-4.93). The results are consistent with findings from other countries, with current knowledge of risk factor profiles of different malignancies and with hypotheses on possible side effects of radiotherapy.  PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB One hundred and seven cases of malignant tumours occurred among 788 women irradiated 1912 to 1977 for metropathia. One hundred and seventy-three women out of 1,219 referred for the same diagnosis and not irradiated developed a malignant tumour. The tumours were diagnosed between 1958 and 1982. The relative risk of malignant tumours among the irradiated women was 1.22 and among the non-irradiated 1.09 compared to cancer *registry* data. A statistically non-significant increase of the relative risk was found in the irradiated patients for tumours of the rectum (1.58), colon (1.46), and the nervous system (1.67). A decreased overall relative risk was seen for cancer of the breast (0.92) after irradiation, but women treated at the age of 50 or more had an increased risk (2.08). The relative cancer risk of the heavily irradiated sites was not increased during the first 20 years after irradiation, but a statistically significant increase of the risk was seen after 30 years.  PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-TUTORIAL (TUT).
 LG English (EN).
 AB Immunoscintigraphy is a new method for in vivo diagnosis of diseases using monoclonal antibodies. Emphasis is placed on diagnosis of malignant tumors although the range of application includes a number of non-malignant diseases. To date, no European country has issued clear guidelines on the testing and registration of those monoclonal antibodies labelled with a radionuclide and used for diagnostic. This involves the risk of overregulation which would considerably

reduce the applicability of the method. This holds particularly true since the complications initially anticipated with the use of such compounds did not occur. The conduct of immunoscintigraphy has evolved during the last few years. For reasons of applicability, but also and mainly for reasons of *radiation* hygiene, I-131 and finally also In-111 were abandoned as labelling nuclides and replaced by Tc-99m. The protein amount involved was reduced. Some false estimations, which were due to particularities or artifacts of the iodinated antibodies used at the beginning, had to be corrected: the representation of the liver in a scintigram is part of the physiological distribution of antibodies; and fragments of antibodies normally do not present the anticipated kinetic advantages. The clinical results obtained with colon carcinomas show that not only recurrences and metastases, but also primary tumors can be detected with equally high sensitivity. In contrast, radioimmunotherapy does not yet seem as successful, at least against solid tumors.

JT INTERNATIONAL JOURNAL OF CANCER.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB The association between X-ray exposure in utero and childhood cancer was studied in a case-control study, nested in a national cohort of Swedish twin births. Records of the Swedish Twin Register for those born 1936-1967 (n = 83,316) were linked to the Swedish Cancer Register (1958-1983) and the Swedish Cause-of-Death Register (1952-1983). Ninety-five cases of childhood cancer before the age of 16 were identified. Two controls from the Twin Register were matched to each case by sex and year of birth. Maternal X-rays during pregnancy were documented for 41% of the cases and 36% of the controls. The crude relative risk of any childhood cancer associated with any prenatal X-ray was 1.2 (95% CI; 0.7-2.1). For the cases 64% of the X-rayed women had had abdominal X-rays, the numbers for the controls were 57%. Fifty-nine per cent of the X-rayed women had had abdominal X-rays, which were associated with a relative risk for all cancers of 1.4 (CI; 0.8-2.5), leukemias 1.7 (CI; 0.7-4.1) and tumors of the central nervous system 1.5 (CI; 0.5-4.2). There was no apparent confounding by mother's age, drug use, obstetric complications, previous miscarriages, social class or length of pregnancy. The observed relative risks of cancer following prenatal X-ray exposure are consistent with previous studies, suggesting that the developing fetus may be more sensitive to the carcinogenic effects of ionizing *radiation* than are children irradiated post-natally. Author-abstract.

Committee of the International Bone Marrow Transplant *Registry.*
SO Bone-Marrow-Transplant. 1990 Jul. 6 Suppl 1. P 94-7.
JT BONE MARROW TRANSPLANTATION.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB We studied 2254 persons receiving HLA-identical sibling bone marrow
transplants for acute myelogenous leukemia (AML) or acute
lymphoblastic leukemia (ALL) in first remission, or chronic
myelogenous leukemia (CML) in first chronic phase to determine
whether graft-versus-leukemia (GvL) reactions are important in
preventing leukemia recurrence after bone marrow transplantation.
Four groups were investigated; recipients of non-T-cell depleted
allografts without graft-versus-host disease (GvHD), recipients of
non-T-cell depleted allografts with GvHD, recipients of T-cell
depleted allografts, and recipients of genetically identical twin
transplants compared with recipients of non-T-cell depleted
allografts without GvHD. Decreased relapse was observed in recipients
of non-T-cell depleted allografts with acute (relative risk 0.68, P
= 0.03), chronic (relative risk, 0.43, P = 0.01), and both acute and
chronic GvHD (relative risk 0.33, P = 0.0001). These data support an
anti-leukemia effect of GvHD. AML patients receiving identical twin
transplants had an increased probability of relapse (relative risk
2.58, P = 0.008) compared to allograft recipients without GvHD
supporting an anti-leukemia effect of allografts independent of GvHD.
CML patients receiving T-cell depleted transplants without GvHD had
a higher probability of relapse (relative risk 6.91, P = 0.0001) than
recipients of non-T-cell depleted allografts without GvHD. These
data support an antileukemia effect independent of GvHD altered by
T-cell depletion. These results indicate that much of the
anti-leukemia effect of bone marrow transplants is related to immune
factors rather than high-dose chemotherapy and/or *radiation.*

JT ACTA OBSTETRICA ET GYNECOLOGICA SCANDINAVICA.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB A cancer *registry* cohort of 16,704 cases of invasive carcinoma of the
uterine cervix and 56,116 cases of in situ carcinomas of the uterine
cervix was followed up and second new primary cancers were recorded.
The invasive carcinomas contributed 127,118 woman-years at risk and
the in situ carcinomas contributed 453,362 woman-years at risk. The
main treatment for the invasive carcinomas had been radiotherapy and
for the in situ carcinomas, conization and other types of surgical
intervention. 767 new primaries occurred after treatment of invasive
carcinoma of the uterine cervix, compared with 644.5 expected. O/E
is 1.19. After the in situ carcinomas, 1,421 malignant tumors were
observed, vs. 1,188.0 expected (O/E 1.19). If, however, cases of
invasive carcinoma of the uterine cervix after in situ carcinomas are
excluded, the ratio observed/expected is 1.10. For some sites the
increased observed/expected ratios were found after both invasive and
in situ carcinomas, which speaks for some common carcinogenic effect
other than irradiation (for instance, in bronchus and trachea,
pharynx, nose, sinus and larynx, but also in rectum, urinary bladder,
other female genital organs, pancreas, lymphosarcoma, as well as
acute and non-lymphatic leukemia). A lower risk than expected--after
both in situ and invasive carcinoma of the uterine cervix--is
observed for breast cancer, cancer of the corpus uteri and for
multiple myeloma. However, analyses based on time since treatment
provide evidence of a carcinogenic effect of irradiation, especially
in intensively irradiated organs such as bladder, rectum, corpus
uteri and ovary, and also for acute and non-lymphatic leukemia.

JT PROGRESS IN CLINICAL AND BIOLOGICAL RESEARCH.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB To date, no agent has been documented to cause germ cell mutation in
human beings, with the possible exception of *radiation* causing
abnormal meiotic chromosomes in testes. For studies in humans,
mutation epidemiologists prefer the cohort approach, starting with an
exposed population and looking for mutations that may be expressed in
offspring as variants in health, chromosomes, proteins, or nucleic
acids. Currently patients with cancer are the cohort exposed to the
largest doses of potential mutagens, i.e., radiotherapy and drugs.
In 12 large studies with over 825 patients and 1573 pregnancies, 46
(4%) of 1240 liveborns had a major birth defect, a rate comparable to
that in the general population. One of these was a classic sentinel
phenotype, i.e., a new sporadic case of a dominant mendelian
syndrome. In collaboration with 5 U.S. cancer *registries,* we
interviewed a retrospective cohort of 2383 patients diagnosed with
cancer under age 20 years, from 1945 through 1975. Records were
sought to verify major genetic disease, defined as a cytogenetic or
single gene disorder or 1 of 15 isolated birth defects. In 2308
offspring of survivors, 5 had a chromosomal syndrome, 11 had a single
gene disorder, and 62 had at least one major malformation. Among
4722 offspring of sibling controls, the respective numbers were 7,
12, and 127, nonsignificant differences. 7% of the parents of the
offspring with possibly new mutations received potentially mutagenic
therapy, compared with 12% of parents of normal children. Since
pregnancy in or by cancer survivors is still a rare event, future
efforts to document germ cell mutation may be best studied through
international cooperation coupled with diverse laboratory measures of
mutation. Author-abstract.

AB A 35 year review of adenocarcinomas of the esophagus was undertaken. We found the disease to be one of increasing incidence afflicting white males disproportionately. Risk factors remain to be clarified. *Radiation* therapy in curative doses and complete resection were competitively effective in terms of long-term survival. No survival advantage was found with palliative surgery compared with other means of therapy. Optimal combinations of treatment remain to be discovered. Author-abstract.

AB In this multicenter case-control study (1,079 melanoma patients, 778 control persons), the significance of the well-known risk factors for the development of malignant melanoma (MM) was assessed for a German population. The multifactorial analysis of the data confirmed the total number of melanocytic nevi (MCN) as the most robust indicator for an increased melanoma risk. For persons with more than 50 MCN the relative risk was 4.8 times as high as for persons with fewer than 10 MCN. Hair color was found to be another valuable indicator. In persons with red hair the risk of MM was 4.7 that in individuals with black hair. Remarkably fair persons with skin type 1 (always sunburn, never tanning) had two times the risk of that in persons with skin type 4 (never sunburn, always tanning). The habit sun bathing for recreation showed no influence on the development of melanoma. A 2.7 x increased melanoma-risk was detected in persons with occupational sun exposure and out of doors work.

AB Population-based data on more than 1 million patients registered in the Surveillance, Epidemiology, and End-Results Program of the National Cancer Institute, 1973 to 1984, were analyzed to determine the survival of patients with de novo acute nonlymphocytic leukemia (ANLL) and following a first primary tumor treated (with chemotherapy and/or *radiation* therapy) or untreated. Cases that occurred within 12 months of the first malignant neoplasm were excluded. Survival was estimated using Cox proportional-hazards modeling, with age, sex, and specific type of ANLL as covariates. The 6271 patients with de

novo ANLL had an estimated 12-month survival of 30%, while the 107 patients with treatment-related ANLL *(radiation* therapy, 60; chemotherapy, 29; both, 18) had an estimated 12-month survival of 10%. This is not due to lingering effects of the first tumor since ANLL following solid tumors not treated with chemotherapy or *radiation* therapy (118 cases) has similar survival (estimated 12-month survival, 36%) as de novo ANLL. We conclude that ANLL that occurs after chemotherapy or *radiation* therapy is biologically more aggressive and/or resistant to therapy than spontaneous ANLL. This provides a rationale for current studies on treatment-induced cellular changes and on more aggressive therapy for these patients. Author-abstract.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB To examine the hypothesis that radiotherapy for breast cancer can cause myocardial infarction, cause-specific mortality by laterality of the primary tumour was analysed among 54,617 breast cancer patients reported to the Swedish Cancer *Registry* during 1970-1985. The rationale was that radiotherapy for a left-sided breast cancer invariably results in higher doses of *radiation* to the myocardium than a similar treatment given for a right-sided tumour whereas other possible risk factors for cardiovascular disease probably are

unrelated to the laterality of the tumour. The median follow-up was 9 years (range 1-17 years). Patients with left-sided tumours were found to have a higher mortality due to myocardial infarction than patients with right-sided tumours (P less than 0.01) but there was no difference in regard to total intercurrent mortality. Further analyses of individual radiotherapy studies are warranted to quantify the excess risk associated with *radiation* and to study the significance of the type of *radiation,* portal arrangements, total dose and fractionation. It seems reasonable to assume that adverse effects of *radiation* are dose-related and may thus be minimised or prevented by the use of appropriate treatment techniques.

AB The risk of a person developing a second primary cancer was evaluated in 1,215 patients with laryngeal cancer at the National Cancer Center Hospital. Overall, 92 (8.2%) of the male patients and 5 (5.7%) of the female patients developed a second cancer, compared with 83.0 and 3.7, respectively, expected on the basis of general population rates, resulting observed: expected values (O/E) to be 1.1 and 1.3. The numbers of second cancers of the lung (O/E = 1.9), oropharynx (O/E = 8.8) and esophagus (O/E = 2.8) were significantly in excess of those expected, while the number of second stomach cancers (O/E = 0.5) was far below expectation. Synchronous second cancers were significantly higher than expected (O/E = 4.6). Smoking, especially heavy smoking, was related to second lung cancers, but alcohol drinking featured less. Histories of benign respiratory tract and digestive organ diseases were related to second oropharyngeal cancers. Alcohol drinking was related to second stomach cancers. *Radiation* therapy for the initial laryngeal cancer was related to second oropharyngeal cancers, while hazardous occupations related to noxious agents for respiratory systems featured more prevalently in cases of second lung

cancer. Further analytical studies should clarify the roles of smoking, drinking, occupation and various forms of therapy on the risk of developing a different second cancer following laryngeal cancer. Author-abstract.

AB The effect of changes in the ozone layer on the incidence of skin cancer was explored using data for Norway. Attempts were made to arrive at a relationship between the "environmental effective UV-dose" and the skin cancer incidence. Norway is well suited for this purpose because of the large variation in the annual UV-dose from north to south. Furthermore we have a well developed cancer *registry* and a homogeneous population with regard to skin type. Four different regions of the country, each with a broadness of 1 degree in latitude (approximately 111 km), were selected (located around 69.5, 63.5, 60 and 58.5 degrees N). The annual effective UV-doses for these regions were calculated, assuming normal ozone conditions throughout the year and the action spectrum proposed by CIE, which extends up to 400 nm. The incidence rate (in the period 1970-1980) of malignant melanoma and non-melanoma skin cancer (mainly basal cell carcinoma) increased with the annual environmental UV-doses. For both these types of cancer a quadratic dose-effect relationship seems to be valid to a first approximation. The present data indicate that the incidence of skin cancer would increase by approximately 2% for each percent ozone reduction. Author-abstract.

AB There are epidemiologic similarities between salivary and skin neoplasms that could be attributed to exposure to ultraviolet *radiation.* To explore further the etiologic parallels between these two types of cancer, we studied the multiple primary association between salivary gland cancer with that of other cancers known to be induced by ultraviolet light exposure, using data from the SEER program for 1973-1984. Because nonmelanoma skin cancers other than cancers of the lip are not routinely reported to the SEER *registries,* we specifically evaluated the associations with melanoma and lip cancers. Expected numbers of subsequent primaries (melanoma and lip) for the 904 white men and 784 white women with an initial salivary gland cancer were computed from incidence rates using the Connecticut Tumor *Registry.* There were significantly increased risks for subsequent lip cancer among men (RR = 8.7) and for melanoma among women (RR = 7.1). Among men there was also a significant association between an initial lip cancer and risk of subsequent salivary gland cancer (RR = 12.7). These observations, together with reported increases in incidence of these tumors, suggest a common etiology, which could partly be explained because of exposure to ultraviolet *radiation.* Author-abstract.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Interstitial pneumonitis is one of the major causes of morbidity and mortality following bone marrow transplantation (BMT). Based on the Japanese BMT *Registry,* however, since 1983 the incidence of interstitial pneumonitis at one year has decreased to 32% by means of several efforts, such as fractionated low-dose rate total body

irradiation, selection of platelet donor from cytomegalovirus (CMV) seronegative donor, and prophylactic administration of anti-CMV high titer globulin. Cytomegalovirus (58%) was the most frequently causative organism within 100 days after bone marrow transplantation. On the other hand, idiopathic interstitial pneumonitis (44%) was the leading cause more than 100 days after bone marrow transplantation. There was a significant difference in onset after bone marrow transplantation against leukemia between cytomegalovirus (mean: 90 +/- 15 days) and idiopathic interstitial pneumonitis (mean: 186 +/- 32 days) (p less than 0.01). PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Investigators in Texas have reported an association between paternal employment in jobs linked with exposure to electromagnetic fields and risk of neuroblastoma in offspring. In an attempt to replicate this finding, the authors conducted a case-control study in Ohio. A total of 101 incident cases of neuroblastoma were identified through the Columbus (Ohio) Children's Hospital Tumor *Registry.* All cases were born sometime during the period 1942-1967. From a statewide roster of birth certificates, four controls were selected for each case, with individual matching on the case's year of birth, race, and sex, and the mother's county of residence at the time of the (index) child's birth. Multiple definitions were employed to infer the potential for paternal occupational exposure to electromagnetic fields from the industry/occupation statements on the birth

certificates. Case-control comparisons revealed adjusted odds ratios ranging in magnitude from 0.5 to 1.9. For two of the exposure definitions employed--both of which are similar to one used by the Texas investigators--the corresponding odds ratios were modestly elevated (odds ratios = 1.6 and 1.9). Notably, the magnitude of these odds ratios is not inconsistent with the Texas findings, where the exposure definition referred to yielded an odds ratio of 2.1. Because the point estimates in this study are imprecise, and because the biologic plausibility of the association is uncertain, the results reported here must be interpreted cautiously. However, the apparent consistency between two independent studies suggests that future evaluation of the association is warranted. Author-abstract.

LG English (EN).
AB The risk of cancer (incidence) prior to age 20 years has been
determined for children born to atomic bomb survivors and to a
suitable comparison group. Tumor ascertainment was through death
certificates and the tumor *registries* maintained in Hiroshima and
Nagasaki. The rationale for the study stemmed from the evidence that
a significant proportion of such childhood tumors as retinoblastoma
and Wilms tumor arise on the basis of a mutant gene inherited from
one parent plus a second somatic cell mutation involving the allele
of this gene. Gonadal *radiation* doses were calculated by the
recently established DS86 system, supplemented by an ad hoc system
for those children for one or both of whose parents a DS86 dose could
not be computed but for whom an ad hoc dose could be developed on the
basis of the available information. The total data set consisted of
(1) a cohort of 31,150 live-born children one or both of whose

parents received greater than 0.01 Sv of *radiation* at the time of the atomic bombings (average conjoint gonad exposure 0.43 Sv) and (2) two suitable comparison groups totaling 41,066 children. Altogether, 43 malignant tumors were ascertained in the children of exposed parents, and 49 malignant tumors were ascertained in the two control groups. A multiple linear regression analysis revealed no increase in malignancy in the children of exposed parents. However, examination of the data suggested that only 3.0-5.0% of the tumors of childhood that were observed in the comparison groups are associated with an inherited genetic predisposition that would be expected to exhibit an altered frequency if the parental mutation rate were increased. There is thus far no confirmation of the positive findings that Nomura found in a mouse system. Author-abstract.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Leukemia following chemotherapy for breast cancer was studied among
patients diagnosed during 1973-1985 within the population-based tumor
registries in the Surveillance, Epidemiology, and End Results
Program. Among 13,734 women given initial chemotherapy, 24 developed
acute nonlymphocytic leukemia (ANLL) compared to 2.1 expected based
on general population rates (observed/expected = 11.5; 95% confidence
interval = 7.4-17.1). Overall, 58 excess ANLL occurred per 100,000
women-years at risk for patients treated with chemotherapy. The
cumulative incidence was 0.7% at 10 years. Risk remained high over
all periods of observation up to 9 years after treatment. Among 7974
women treated only with surgery during 1973 and 1974, a period before
the widespread use of adjuvant chemotherapy for breast cancer, ANLL
was not significantly increased (observed = 7, expected = 5.1). A
case-control study was then conducted in Connecticut to evaluate in
more detail the risk associated with adjuvant chemotherapy in the
general population. Among 20 cases (17 incident leukemias and 3
deaths due to preleukemia) and 60 matched controls, alkylating agents
were linked to an 11.9-fold risk of ANLL and preleukemia (95%
confidence interval = 2.6-55). Chemotherapy regimens including
melphalan were related to a higher risk of leukemic conditions than
those including cyclophosphamide. These data suggest that women in
the general population treated with adjuvant chemotherapy for breast
cancer are at an increased risk of leukemia, that the risk remains
high among long-term survivors, and that risk differs by type of
alkylating agent administered. Author-abstract.

PT JOURNAL-ARTICLE (ART).
LG Serbo-Croatian (Roman) (SR).
AB The Institute for Medical Protection of Mothers and Children, being regional centre of European *registry* of congenital malformations (EUROCAT) since 1982, registers congenital anomalies in municipalities of Varazdin and Rijeka. Following the nuclear disaster of Chernobyl, there were numerous articles published mainly in daily newspapers, pointing to the increased number of malformations, particularly to Down's syndrome, due to additional irradiation imposed on population. Through this study we wanted to find out whether in Varazdin and Rijeka, following the Chernobyl's accident, there has been any increase of congenital anomalies and whether our regional and EUROCAT *registry* have been adequate to find out genetic effects of small doses of ionizing *radiation.* The total incidence of registered congenital anomalies in Varazdin and Rijeka in previous four-year period, amounted to 12.97%, while following Chernobyl, it amounted to 12.7%. Not even nine marker malformations, including Down's syndrome, show any statistically significant increased number of malformations, a year after this nuclear accident. In 18 EUROCAT *registries,* on almost half a million of newly born children and fetuses, conceived before and after May 1, 1986, the frequency of Down's syndrome and congenital malformations of central nervous system and eyes has been compared. There have been no important differences between two compared groups, and the rate of Down's syndrome was 1.26% before, and 0.91% after the accident. Anticipated stochastic genetic effects of measured and estimated additional doses of *radiation* imposed to our and Western European populations are too small to be found out neither by regional nor by EUROCAT *registries.* Author-abstract.

AB The available information on treatment of sinus histiocytosis with massive lymphadenopathy (SHML) was reviewed. Treatment is not necessary in most instances, but some patients may require surgery, *radiation* therapy, and/or chemotherapy because of severe disease manifestations. An ideal treatment has yet to be identified. Of the various chemotherapeutic regimens that have been tried so far, a combination of vinca alkaloid, alkylating agent, and corticosteroid appears to be the most effective. Author-abstract. 49 Refs.

PT JOURNAL-ARTICLE (ART).
LG Japanese (JA).
AB To determine risk factors in childhood malignancy, we compared parental and fetal exposure rates of some environmental factors among major children's malignancies based on 2722 cases of the Japan

Children's Cancer *Registry* Database. The rates of parental exposure to irradiation, chemicals, and maternal dosage before and during pregnancies and of maternal smoking and drinking habit during pregnancies were slightly but statistically significantly high in some blastomas in which loss of heterozygosity of the genes has been reported. On the other hand, there were no significant correlations with these factors in leukemia and malignant lymphoma, which have been reported to be related to special chromosomal translocations. These possible risk factors should be examined by experimental and more detailed epidemiological studies. Author-abstract.

AB In Denmark, as in many other countries, the incidence of thyroid cancer is increasing, while mortality from this disease is decreasing. The proportionate distribution of cell types is similar to that seen elsewhere. The increase in incidence in other countries has been attributed to the increased use of *radiation* for benign conditions of the head and neck. This cannot explain the increase in incidence in Denmark, and other factors may contribute importantly to the changing picture of thyroid cancer. Author-abstract.

 AB Problems related to environmental carcinogenesis have begun to surface with increased industrial activity and diffusion of hazardous chemicals. Cancer *Registries* maintained in some of our cities can help in retrospectively analysing incidence and related aetiology. Even a casual analysis of the existing data related aetiology. Even a casual analysis of the existing data belies the oversimplicity of the WHO model used in developing countries to assign lower priority to cancer prevention and control than to communicable diseases. Exposure data to environmental inducers of cancer, *radiations,* chemicals and other stresses is urgently needed. Prevention strategy should be more and more on a scientific base for an early detection and risk estimates of chemical exposures. Sustained environmental monitoring for inducers and cofactors are required. The Factory Act must make provision for appropriate health surveillance of workers over a long period.  PT JOURNAL-ARTICLE (ART).
 LG Japanese (JA).
 AB From the data in vol. 6 of Brain Tumor *Registry* in Japan, there were
 mainly analyzed the survival rates of malignant astrocytoma and
 glioblastoma patients related to extent of surgical removal and
 postoperative *radiation.* Total removal of the supratentorial
 astrocytoma in brain revealed 75.9% in 5-year survival rate, whereas
 supratentorial malignant astrocytomas and glioblastomas, 43.7% and
 20.9% in 5-year survival rates, respectively. Survival rates related
 to combination of operation and *radiation* therapy for the
 glioblastoma and malignant astrocytoma patients were analyzed
 according to the mode of operation. For glioblastomas, patients
 treated with biopsy and post-operative *radiation* therapy indicated
 higher survival rate of 6.3% in 5-year survival than the patients
 with biopsy and no *radiation,* 3.0% of 5-year survival rates (P less
 than 0.01 by Chi-square test). On the other hand, patients treated
 with 95%-100% removal by operation with or without *radiation* therapy
 showed 67.2% (with), 32.1% (without) in 1 year survival; 37.2%, 23.1%
 in 2 year survival; 27.1%, 20.0% in 3 year survival; 22.5%, 20.2% in
 4 year survival and 20.4% and 19.4% in 5-year survival rates,
 respectively (P less than 0.05 by Chi-square test). Tentative TNM
 classification proposed by Japan to UICC was also discussed briefly.

 AB Uterine sarcomas are uncommon malignancies. We retrospectively
 examined 24 cases of "high grade" endometrial stromal sarcomas (ESS).
 The histologic diagnosis was made if there was a high grade sarcoma
 with a high mitotic index and nuclear anaplasia. Heterologous
 elements could be present, if focal only. Leiomyosarcomas, mixed
 mesodermal sarcomas, and carcinosarcomas were excluded. Mitotic
 index was expressed as the number of mitoses per 10 high-power fields
 in active areas. Tumor grade was based on nuclear anaplasia. ESS
 were 5.7% of all uterine sarcomas. Median age was 58.2 years; median
 duration of symptoms was 67.5 days. Abnormal bleeding was the
 presenting complaint in 91.7%. Uterine enlargement was seen in 33%;
 protrusion through the cervical os was seen in 9 cases. Total
 abdominal hysterectomy and bilateral salpingo-oophorectomy was
 performed in 95.8%. Twenty patients had myometrial involvement; 5
 patients had serosal spread and extrauterine disease; residual
 disease was seen in 3 patients. Adjuvant *radiation* was not
 beneficial. Ten patients had recurrences: 60% in the pelvis, 50%
 each with subcomponent of abdominal or distant disease. Overall
 survival was 3.4 years and was significantly associated with extent
 of disease, size of the primary tumor, and grade. Author-abstract.

AB The development of second malignant tumors (SMTs), in patients who have had their first tumor treated successfully, represents a serious limitation of current therapeutic strategies for head and neck cancers. To improve our understanding of the current magnitude of the problem and the various factors that might influence its importance, we reviewed the *Radiation* Therapy Oncology Group's (RTOG) prospectively collected *registry* of all head and neck patients seen in participating member institutions between February 1977 and April 1980. A total of 928 patients were identified who had squamous cell carcinomas of the head and neck region, no prior or coincident history of another malignant tumor, and whose planned treatment consisted of *radiation* therapy only. A total of 110 second, independent, malignant tumors occurred in these patients. Overall, the estimated risk of developing a second tumor within 3 years of radiotherapy was 10%, within 5 years 15%, and within 8 years 23%. Minor differences in frequency were observed for different primary sites. These SMTs unquestionably influenced subsequent survival adversely. Analysis of the database also revealed that the extent of the primary tumor influenced the risk of a second; most occurred in patients who presented with the smallest primary tumors because of their better survival. Our data indicate that preventive medicine should have its greatest impact in those patients who are treated for an early stage primary tumor. Author-abstract. 25 Refs.

TI Biological amplification factor for sunlight-induced nonmelanoma skin cancer at high latitudes.

SO Cancer-Res. 1989 Sep 15. 49(18). P 5207-12.

JT CANCER RESEARCH.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Data for the incidence of basal cell carcinomas (BCCs) and squamous cell carcinomas (SCCs) of the skin, registered for six regions of Norway during 10 years (1976-1985), were used to evaluate the biological amplification factor Ab for induction of these cancers by sunlight. Ab is the ratio of the increment in skin cancer production to the increment in causative sunlight exposure. Two different approximations were used for the action spectrum for carcinogenesis: an erythema action spectrum; and an action spectrum for mutagenesis of cells in the basal layer of the skin. These two fundamentally different approaches yielded Ab values that were similar to within about 10%: 2.1-2.3 for BCCs; and 1.6-1.8 for SCCs. Using a *radiation* amplification factor for ozone depletion of 0.8-1.1, we find that the total amplification factor for BCCs is within the range 1.6-2.1 and that that for SCCs is within the range 1.3-1.7 at northern latitudes of 60-70 degrees. Thus, an ozone depletion of 1% will result in an increase in the incidence of BCCs by 1.6-2.1% and of SCCs by 1.3-1.7%. There were no significant differences between the values for men and women. Neither was there any significant difference between Ab values found for skin commonly exposed to sunlight (face) and for skin sites normally covered by clothes and therefore receiving much lower exposures, in spite of the fact that the tumor density per unit skin area was a factor of 20 or more larger at the former sites. This observation, as well as the curves relating cancer incidence with annual exposure to carcinogenic sunlight, supports a power law relationship between cancer incidence and annual sun exposure. Sunlight appears to be the main cause of BCCs and SCCs even at the high latitudes of Northern Norway. All over, BCCs were found to be about 6 times more frequent than SCCs. The ratio of the incidence of BCCs to that of SCCs seemed to be independent of the latitude. Finally, BCCs were found to be equally frequent among men and women, while SCCs were found to be about twice as frequent among men as among women. Author-abstract.

 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB The incidence of leukaemia and non-Hodgkin's lymphoma in young people
 (aged under 25) living in a predefined area around the nuclear power
 station at Hinkley Point, Somerset, was examined for the period
 1959-86 by using cancer *registry* data. During the period since
 Hinkley Point began operations--that is, 1964-86--there were 19 cases
 in the area compared with 10.4 expected from national rates, giving
 a standardised registration ratio of 1.82 (95% confidence interval
 1.10 to 2.85). The incidence in the rest of Somerset was also high,
 however (standardised registration ratio 1.18; 95% confidence
 interval 0.98 to 1.41), and the high rate around Hinkley Point may
 simply have been reflecting the high local incidence (ratio of the
 two standardised registration ratio's 1.54; 95% confidence interval
 0.90 to 2.52). Analysis of predetermined five year periods showed

that the excess cases in the Hinkley Point area were concentrated in the 10 years 1964-73 after commissioning of the station, at a time when rates in the rest of Somerset were close to the national average. In particular the nine cases occurring in the five years 1969-73 were about four times the number expected from national rates (standardised registration ratio 3.96; 95% confidence interval 1.81 to 7.52). Rates in the Hinkley Point area after 1973 were fairly low, especially as compared with the rest of Somerset. In the five years 1959-63 (that is, before Hinkley Point was commissioned) rates throughout Somerset (including the Hinkley Point area) were higher than the national rate. These findings should be interpreted with caution, and further studies are required to test the plausibility of theories relating to *radiation* and viruses. Author-abstract.

AB A series of 34 pinealomas and intracranial germinomas in childhood (age less than 20), from two tumor *registries,* is analyzed. Male to female ratio was 2:1. Median age was 12 years. Visual complaints and endocrine disturbances were the most common presenting symptoms. Papilledema, visual field deficits, and oculomotor abnormalities were the principal findings at diagnosis. Cumulative probability of survival (CPS) of the entire series at one year was 0.65, at two years 0.54, and at five years 0.54. Best survival was with treatment by operation and *radiation:* CPS at one year was 0.82, at two years 0.82, and at five years still 0.82. Survival was similar with pineal region tumors and with suprasellar tumors. Most long-term survivors, particularly with suprasellar germinomas, had permanent hormonal deficits requiring replacement therapy. Author-abstract.

AB Uranium concentrations were radiochemically determined in samples of lung, kidney, liver and bone collected at autopsy from an occupationally exposed individual. Levels of U in these tissues were

clearly in excess of those expected from environmental exposure. Deposition followed the pattern: skeleton greater than liver greater than kidney, with ratios of 63:2.8:1. The data suggest there is an important long-term storage depot in the skeleton, but the fraction transferred to this compartment, as proposed by ICRP 30, may be too small. In vivo chest counts obtained over about a 10-y period prior to death indicated about a factor of 2 greater in total U content and 235U enrichment than deposition estimates made at autopsy for the lungs and associated lymph nodes. TI Dysgerminoma: a study of 13 cases from the Connecticut Tumor *Registry.*

SO Conn-Med. 1989 Apr. 53(4). P 207-9.

JT CONNECTICUT MEDICINE.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Thirteen cases of patients with dysgerminoma of the ovary, accrued from the Connecticut Tumor *Registry* from 1974-84, were reviewed. Seven of the 13 patients were stage I at the time of initial surgery. Two of these patients had a diagnosis of dysgerminoma arising within a gonadoblastoma. Five of the seven patients were treated with some form of adnexal surgery; one patient received adjuvant combination chemotherapy consisting of vincristine, dactinomycin, and cyclophosphamide (VAC) and another received *radiation* therapy. Two of the seven patients were treated with total abdominal hysterectomy and bilateral salpingo-oophorectomy (TAH/BSO) plus *radiation* therapy. One patient, whose tumor recurred after initial therapy with unilateral oophorectomy, was successfully treated with *radiation* therapy. Six patients had advanced disease at the time of initial surgery. One patient with stage II disease and three patients with stage III disease were treated with TAH/BSO plus *radiation* therapy. One patient with stage III disease was treated with unilateral adnexectomy plus combination chemotherapy consisting of vinblastine, bleomycin, dactinomycin, cyclophosphamide, and cisplatin (VAB-VI).

One patient with stage IV disease was treated with decompressive laminectomy with tumor resection, removal of left pelvic mass, *radiation* therapy and adjuvant combination chemotherapy (VAC). In our series, no patient died from dysgerminoma (one patient died of an apparently unrelated cause). The role of *radiation* therapy in the treatment of advanced and recurrent dysgerminoma has been demonstrated. However, the use of combination chemotherapy has been playing an increasingly important role in patients treated with conservative surgery in which preservation of fertility is a concern. JT HUMAN GENETICS.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB The Hungarian surveillance of germinal mutations is based on three indicator conditions seen in offspring, i.e., 15 sentinel anomalies, Down syndrome and component anomaly pairs of unidentified multiple congenital anomalies. It is an "opportunistic program," because the necessary data are available from the Hungarian Congenital Malformation *Registry.* This system is described and the criteria of a good *registry* are summarized. The analysis of indicator conditions caused by germinal mutations did not reveal any measurable mutagenic effects in Hungary following the accident at the Chernobyl nuclear power plant. The pros and cons of germinal mutation surveillance are discussed. Author-abstract.

SO Gynecol-Oncol. 1989 Jul. 34(1). P 46-9.
JT GYNECOLOGIC ONCOLOGY.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Twenty-five cases of patients with pure immature teratoma of the
ovary, accrued from the Connecticut Tumor *Registry* from 1969 to 1984,
were reviewed. Two patients had grade 1 tumors, twelve had grade 2
tumors, and eleven had grade 3 tumors. The majority of patients (23)
were stage I at the time of initial surgery. Twenty-one of the
twenty-three patients were treated with some form of unilateral
adnexal surgery with or without adjuvant combination chemotherapy
(VAC). Two of the twenty-three patients were treated with total
abdominal hysterectomy/bilateral salpingo-oophorectomy (TAH/BSO) with
the addition of either VAC chemotherapy or *radiation* therapy.
Recurrence occurred in two patients, both of whom had grade 3 tumors
and were subsequently treated with surgical resection plus VAC
chemotherapy. One patient, who recurred after initial therapy with
unilateral salpingo-oophorectomy (USO) plus VAC chemotherapy, was
successfully treated with surgical resection and further
chemotherapy. Two patients were stage III at the time of initial
surgery, one of whom was treated with USO plus adjuvant combination
chemotherapy and radio-therapy. The other patient was treated with
TAH/BSO plus VAC chemotherapy. In our series, no patient died from
immature teratoma (one patient died from advanced breast carcinoma).
It is reasonable to withhold chemotherapy from patients with stage I,
grade 1 and 2, immature teratoma which may be treated initially with
conservative surgery. The risk of recurrence in patients with grade
3 tumors warrants the addition of further chemotherapy.

TI Long-term survivors of small-cell carcinoma of the lung.
SO W-V-Med-J. 1989 May. 85(5). P 183-6.

JT WEST VIRGINIA MEDICAL JOURNAL.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Small-cell carcinoma of the lung has been shown to be quite responsive to chemotherapy. Unfortunately, these responses are often short in duration, and long-term, disease-free survival is infrequent. This review of tumor *registry* records of all patients with small-cell carcinoma of the lung treated at Charleston Area Medical Center (CAMC) from 1962 to 1983 showed that 21 of 500 (four per cent) survived 30 months or longer. Eighteen patients had limited-extent disease. Although the majority of patients received chemotherapy alone or chemotherapy and *radiation,* there were survivors in all treatment groups (i.e. surgery alone or radiotherapy alone). Six of the 21 long-term survivors eventually had relapses occurring as late as 88 months after diagnosis. The overall poor survival of patients with small-cell lung cancer suggests a need for the development of novel initial approaches to therapy. Author-abstract.

PT JOURNAL-ARTICLE (ART). REVIEW (REV). REVIEW-MULTICASE (RMC).

LG English (EN).

AB Radon, an inert gas released during the decay of uranium-238, is ubiquitous in indoor and outdoor air and contaminates many underground mines. Extensive epidemiologic evidence from studies of underground miners and complementary animal data have documented that radon causes lung cancer in smokers and nonsmokers. Radon must also be considered a potentially important cause of lung cancer for the general population, which is exposed through contamination of indoor air by radon from soil, water, and building materials. This review describes radon's sources, levels in U.S. homes, dosimetry, the epidemiologic evidence from studies of miners and the general

population, and the principal, recent risk assessments.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Fifty-two patients with carcinoma of the fallopian tube diagnosed and
treated during a 5-year period in Denmark were reviewed. The median
age of the patients was 60 years. No patients had a preoperative
diagnosis. History and clinical findings were similar to previously
reported series. Treatment consisted of hysterectomy and bilateral
salpingo-oophorectomy, often succeeded by postoperative whole pelvic
irradiation. Five-year survival was 37.4%, depending on stage. In
stage I+II the survival rates were similar regardless of whether
postoperative *radiation* therapy had been given or not. Little is
known about the patterns of spread. The relatively bad prognosis for
stages I and II after radical surgery indicates early undetected
metastases and the need for more aggressive adjunctive therapy.

PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB The teratological impact of radiological contamination from the Chernobyl accident was evaluated in relation to central nervous system and eye defects in 18 regional *registries* in nine countries of Western Europe. Six classes of anomaly were analysed: neural tube defects, arhinencephaly, microcephaly and brain reduction, hydrocephaly, anophthalmos and microphthalmos, and congenital cataract. Conceptions up to 31 August 1986 were grouped into two exposure cohorts. In cohort A the sensitive period of fetal development to *radiation* fell wholly or partly between 1 May and 30 June 1986. Cohort B included all cases exposed during their sensitive period on or after 1 May 1986. Observed frequencies of the six classes of anomaly in the exposed cohorts were compared with expected frequencies calculated from baseline rates for the period 1980-1985. The only significant increase was neural tube defects in Odense, Denmark (four cases observed in cohort A where 0.9 were expected). The results of the study do not show a general increase in the frequency of malformations in the countries of Western Europe. The evidence presented indicates that, in the regions studied, termination of pregnancies or invasive prenatal diagnostic examinations were not justified for women exposed during pregnancy. Author-abstract.

AB Each year, tens of thousands of persons are diagnosed with cancer, are treated, and become survivors while still in their reproductive years. Their concerns about possible germ-cell damage as a result of life-saving *radiation,* chemotherapy, or both are plausible, based on evidence from animal models and from somatic cell mutations in human beings. A 40-year follow-up of survivors of the atomic bomb blasts in Japan showed no detectable genetic damage and suggested that the human gonad is more resistant to radiogenic mutation than the laboratory mouse. The pooled results of studying 12 series of offspring of cancer patients showed a 4% rate of major birth defects (similar to that of the general population) and an excess of fetal loss and low birth weight in offspring of women who received abdominal radiotherapy. According to preliminary evaluation of a new National Cancer Institute collaboration with five cancer *registries,* offspring of survivors of childhood cancers had no more birth defects than expected and, beyond an increase in probably familial cancers in children younger than 5, no overall increase in childhood cancer. Ideally, genetic and reproductive counseling should take place as soon as cancer is diagnosed (before therapy starts) and again when pregnancy is contemplated. Author-abstract. 28 Refs.

TI Effect of *radiation* therapy on bronchial obstruction due to

bronchogenic carcinoma.

SO Chest. 1989 Mar. 95(3). P 582-4.

JT CHEST.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB We evaluated the effect of *radiation* therapy in 57 patients with obstruction of a large bronchus with NSCC. Response with aeration of the atelectatic lung was seen in 12 patients (21 percent). Three patients (5 percent) showed partial response with persistent partial atelectasis, and nine patients (16 percent) showed good response with complete aeration of the atelectatic lung. In these patients the response appeared to be related to the dose of *radiation.* All of the patients who responded received more than 50 Gy. The difference in the response rate related to the dose of *radiation* was statistically significant (p less than 0.05). The rates were similar with all histologic types of NSCC. Regardless of the clinical response observed, bronchoscopy performed two to four months after completion of *radiation* therapy in 14 patients revealed persistent endobronchial tumor. There was no significant relationship between the persistence of endobronchial tumor, the dose of *radiation* therapy, and the tumor's histologic type. Of the 12 patients with radiographic improvement in atelectasis, fibrotic changes developed in four (33 percent) patients and pneumonitis in two (17 percent). Progression of disease with distant metastases occurred in 58 percent (seven) of the 12 patients who showed a clinical response of their bronchial obstruction. The median time to survival was nearly identical in responders and nonresponders. Author-abstract.

TI Selection criteria for local excision with or without adjuvant *radiation* therapy for rectal cancer.

SO Cancer. 1989 Apr 1. 63(7). P 1421-9.

JT CANCER.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB As an alternative to radical surgery, local excision with or without adjuvant pelvic *radiation* therapy has been used in selected patients with rectal cancer. To determine which clinical and pathologic features can predict the presence of positive lymph nodes (LN+), a retrospective review of 168 patients who underwent potentially curative surgery for rectosigmoid and rectal cancer was performed. By univariate analysis, tumor penetration, grade, and histology were significant predictive features. This was confirmed by logistic regression analysis. The incidence of LN+ increased with increasing tumor penetration (T1, 0%; T2, 28%; T3, 36%; T4, 53%; $P = 0.04$), grade of adenocarcinoma (well-differentiated, 0%; moderately differentiated, 30%; poorly differentiated, 50%; $P = 0.07$, `borderline significance:), and the presence of any colloid histology (pure adenocarcinoma, 30%; total colloid, 52%; $P = 0.04$). Using 2 X 2 contingency tables, the presence of blood vessel invasion (BVI), lymphatic vessel invasion (LVI), vascular invasion (VI), total colloid histology, and high grade further increased the incidence of LN+ with increasing tumor penetration. Regardless of tumor size, grade, histology, BVI, LVI, or VI, none of the nine patients with Stage T1 tumors or the seven with well-differentiated adenocarcinomas had LN+. For this group, local excision alone is recommended. The incidence of LN+ was greater than or equal to 19% in all other categories. For this group of patients, if there is no evidence of gross tumor in the pelvis, then a local excision plus adjuvant pelvic *radiation* may be an alternative to radical surgery.

 TI Mortality and career *radiation* doses for workers at a commercial
 nuclear power plant: feasibility study.
 SO Health-Phys. 1989 Feb. 56(2). P 139-50.
 JT HEALTH PHYSICS.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB Career *radiation* doses for 8,961 male workers at the Calvert Cliffs
 Nuclear Power Plant (CCNPP) were determined for both utility (n =
 4,960) and contractor (n = 4,001) employees. Workers were followed
 from the time of first employment at CCNPP (including plant
 construction) to the end of 1984 (mean follow-up = 5.4 y). Plant
 operation began in 1975. The mean duration of employment was 1.9 y
 at CCNPP and 3.1 y in the nuclear industry. Career *radiation* doses
 were determined from dosimetry records kept by the utility company
 and the U.S. Nuclear Regulatory Commission (NRC). For all exposed
 workers, the average career dose was 21 mSv and was higher for
 contractor (30 mSv) than utility (13 mSv) workers. Career doses were
 also higher among those employed in the nuclear industry for greater
 than or equal to 15 y (111 mSv) and among workers classified as
 health physicists (56 mSv). Cumulative doses of greater than or
 equal to 50 mSv were received by 12% of the workers; the maximum
 career dose reported was 470 mSv. The availability of social
 security numbers for practically all employees facilitated
 record-linkage methods to determine mortality; 161 deaths were
 identified. On average the workers experienced mortality from all
 causes that was 15% less than that of the general population of the
 U.S., probably due to healthier members of the population being
 selected for employment. Our investigation demonstrates that
 historical information is available from which career doses could be
 constructed and that, in principle, it is feasible to conduct
 epidemiologic studies of nuclear power plant workers in the U.S.
 Although difficult, the approach taken could prove useful until such
 time as a comprehensive *registry* of U.S. *radiation* workers is
 established. Author-abstract.

 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB Data from 208 patients with leukemia who were treated with allogeneic
 bone marrow transplantation between 1975 and 1985 were reported to
 the Japanese Bone Marrow Transplant *Registry* and were available for
 this analysis. These patients were classified into 82 of acute
 lymphocytic leukemia, 91 of acute non-lymphocytic leukemia, and 35 of
 chronic myelocytic leukemia. The incidence of interstitial
 pneumonitis (IP) was 39% (81/208) and fatality rate was 60% (49/81).
 Cytomegalovirus was the most frequent causative organism (54%).
 Using Cox's proportional hazard regression model, age of recipient (P
 $= 0.0068$), status of disease ($P = 0.0191$), and number of platelet
 transfusion ($P = 0.0425$) were found to be significant risk factors
 associated with IP. Probabilities of developing IP at three years
 were 65% and 42% in single dose and fractionated total body
 irradiation (TBI), respectively. In single dose TBI group, dose-rate
 affected the incidence of IP. On the contrary, in fractionated TBI
 group, number of fractions as well as dose-rate had no impact on the
 incidence of IP. Author-abstract.

 TI Solar considerations in the development of cutaneous melanoma.
 SO Semin-Oncol. 1988 Dec. 15(6). P 494-9.
 JT SEMINARS IN ONCOLOGY.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).

AB On the basis of these considerations, the possible action spectrum for melanoma can be narrowed considerably, but not confined to any one solar emission band. The physical factors discussed eliminate all but UV, visible, and NIR *radiation* as possible solar agents. Ionizing *radiation* fits neither the epidemiologic data nor first-order physical considerations. Wavelengths longer than the NIR wavelengths, although they could conceivably account for the occurrence of melanoma under clothed parts of the body, carry so little energy that they are probably unimportant. Epidemiologic evidence regarding the effects of skin pigment favors UV or visible *radiation.* A distinction between these two components is not obvious; UV-C and UV-B photons carry greater energy and are more likely to induce biochemical cutaneous effects, but the total flux in the UV-A and visible *radiations* is far greater. That UV-B *radiation* may play a role in melanoma is supported; at the same time, one cannot exclude the possibility that the action spectrum for melanoma is, instead, the UV-A, the visible, or even the NIR portion of the sunlight spectrum. The strong differential effect of altitude on the transmission of light of different wavelengths might serve as an important discriminating variable. If solar UV *radiation* is implicated in the development of melanoma, then altitude should emerge as a significant factor in epidemiologic studies. If visible or IR *radiation* is the active agent, then differences on the basis of altitude should be small or negligible. Intrinsic solar variations that follow the annual sunspot number appear inadequate in either the UV or the visible band to account directly for the apparent 11-year modulation of melanoma incidence found in some *registries.* Secondary atmospheric effects brought about by the action of solar UV changes on the ozone layer may be adequate to explain a weak 11-year modulation in melanoma incidence, although continuous measurements of UV-B flux made at sites in the United States through a full solar cycle have shown no such effect. Nor do these early measurements reveal the long-term increase in UV-B intensity expected from the destruction of stratospheric ozone by industrial pollutants over the last 10 years. Author-abstract.

TI Leukemia risk following radiotherapy for breast cancer.

SO J-Clin-Oncol. 1989 Jan. 7(1). P 21-9.

JT JOURNAL OF CLINICAL ONCOLOGY.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB To evaluate further the relationship between high-dose radiotherapy and leukemia incidence, a nested case-control study was conducted in a cohort of 22,753 women who were 18-month survivors of invasive breast cancer diagnosed from 1935 to 1972. Women treated for breast cancer after 1973 were excluded to minimize the possible confounding influence of treatment with chemotherapeutic agents. The cases had histologically confirmed leukemia reported to the Connecticut Tumor *Registry* (CTR) between 1935 and 1984. A total of 48 cases of leukemia following breast cancer were included in the study. Two controls were individually matched to each leukemia case on the basis of age, calendar year when diagnosed with breast cancer, and survival time. Leukemia diagnoses were verified by one hematologist. *Radiation* dose to active bone marrow was estimated by medical physicists on the basis of the original radiotherapy records of study subjects. Local *radiation* doses to each of the 16 bone marrow components for each patient were reconstructed; the dose averaged over the entire body was 530 rad (5.3 Gy). Based on this dosage and assuming a linear relationship between dose and affect, a relative risk (RR) in excess of 10 would have been expected. However, there was little evidence that radiotherapy increased the overall risk of leukemia (RR = 1.16; 90% confidence interval `CI:, 0.6 to 2.1). The risk of chronic lymphocytic leukemia, one of the few malignancies without evidence for an association with ionizing *radiation,* was not significantly increased (RR = 1.8; n = 10); nor was the risk for all other forms of leukemia (RR = 1.0; n = 38). There was no indication that risk varied over categories of *radiation* dose. These data exclude an association between leukemia and radiotherapy for breast cancer of 2.2-fold with 90% confidence, and provide further evidence that cell death predominates over cell transformation when high *radiation* doses are delivered to limited volumes of tissue. Author-abstract.

 AB A strong male predominance (4/1) has been noticed in all series of
 hairy cell leukemia (HCL) and we wonder whether there could be a link
 between male predominance and occupation. From a series of 161
 patients observed by two different groups, the repartition of
 profession suggest an aetiological link between HCL and occupational
 exposure, particularly *radiation,* benzene and other solvents, since
 it appears that the proportion of medical workers (6%), mechanic
 divers (22%), printers and painters (10%) and farmers (11%) represent
 a high proportion of patients. Aware of the relative rarity of the
 disease we suggested to set up a national *registry* of the cases of
 HCL, the precise incidence of which remains unknown, and to start a
 classical case-referent study. Author-abstract.

 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB A population-based case-control study was conducted with 338 patients
 less than 15 years of age who were diagnosed with a primary tumor of
 the central nervous system from January 1968 through December 1977 in
 53 contiguous New York counties. The study also included 676

controls who were selected from the birth certificate files of the New York State Department of Health. Parental occupational exposures at the time of each child's birth and at the time of tumor diagnosis were derived from maternal interviews. The current data set failed to show any consistent association between childhood central nervous system tumor risk and paternal occupational exposures to hydrocarbons or to electromagnetic fields, or employment in the aerospace industry or pulp and paper manufacturing. Findings for occupational exposures to ionizing *radiation* were also inconsistent. A positive association was observed between central nervous system tumor risk and paternal exposures to ionizing *radiation* based on industrial codes. Odds ratios ranged from 1.71 to 2.15. This association was not observed when paternal occupational titles were used to define exposure (range of odds ratios, 1.01-1.10). Maternal exposures to ionizing *radiation* were not related to risk regardless of the classification scheme used. Author-abstract.

AB The risk of cancer associated with a broad range of organ doses was
estimated in an international study of women with cervical cancer.
Among 150,000 patients reported to one of 19 population-based cancer
registries or treated in any of 20 oncology clinics, 4188 women with
second cancers and 6880 matched controls were selected for detailed
study. *Radiation* doses for selected organs were reconstructed for
each patient on the basis of her original radiotherapy records. Very
high doses, on the order of several hundred gray, were found to
increase the risk of cancers of the bladder `relative risk (RR) =

4.0:; rectum (RR = 1.8), vagina (RR = 2.7), and possibly bone (RR = 1.3), uterine corpus (RR = 1.3), cecum (RR = 1.5), and non-Hodgkin's lymphoma (RR = 2.5). For all female genital cancers taken together, a sharp dose-response gradient was observed, reaching fivefold for doses more than 150 Gy. Several gray increased the risk of stomach cancer (RR = 2.1) and leukemia (RR = 2.0). Although cancer of the pancreas was elevated, there was no evidence of a dose-dependent risk. Cancer of the kidney was significantly increased among 15-year survivors. A nonsignificant twofold risk of radiogenic thyroid cancer was observed following an average dose of only 0.11 Gy.

Breast cancer was not increased overall, despite an average dose of 0.31 Gy and 953 cases available for evaluation (RR = 0.9); there was, however, a weak suggestion of a dose response among women whose ovaries had been surgically removed. Doses greater than 6 Gy to the ovaries reduced breast cancer risk by 44%. A significant deficit of ovarian cancer was observed within 5 years of radiotherapy; in contrast, a dose response was suggested among 10-year survivors.

Radiation was not found to increase the overall risk of cancers of the small intestine, colon, ovary, vulva, connective tissue, breast, Hodgkin's disease, multiple myeloma, or chronic lymphocytic leukemia. For most cancers associated with *radiation,* risks were highest among long-term survivors and appeared concentrated among women irradiated at relatively younger ages. Author-abstract.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB We investigated the relation between radiotherapy in childhood for tinea capitis and the later development of tumors of the brain and

nervous system among 10,834 patients treated between 1948 and 1960 in Israel. Benign and malignant tumors were identified from the pathology records of all Israeli hospitals and from Israeli national cancer and death *registries.* Doses of *radiation* to the neural tissue were retrospectively estimated for each patient (mean, 1.5 Gy). Sixty neural tumors developed in the patients exposed as children, and the 30-year cumulative risk (+/- SE) was 0.8 +/- 0.2 percent. The incidence of tumors was 1.8 per 10,000 persons per year. The estimated relative risk as compared with that for 10,834 matched general-population controls and 5392 siblings who had not been irradiated was 6.9 (95 percent confidence interval, 4.1 to 11.6) for all tumors and 8.4 (confidence interval, 4.8 to 14.8) when the analysis was restricted to neural tumors of the head and neck. Increased risks were apparent for meningiomas (relative risk, 9.5; n = 19), gliomas (relative risk, 2.6; n = 7), nerve-sheath tumors (relative risk, 18.8; n = 25), and other neural tumors (relative risk, 3.4; n = 9). A strong dose--response relation was found, with the relative risk approaching 20 after estimated doses of approximately 2.5 Gy. Our study confirms that *radiation* doses on the order of 1 to 2 Gy can significantly increase the risk of neural tumors. Author-abstract.

LG English (EN).

AB The summation and classification of patients registered for planned *radiation* therapy in the 24-year period from 1962 to 1986, in the Department of *Radiation* Therapy, National Cancer Center Hospital, are reported. Patients numbered 16,471, and total sessions of treatment were 26,175. The ratio of the two figures, 1.58, is the average number of treatment sessions per patient. Peak age was 61-65 years' old and 56-60 years old, respectively for males and females. The most frequent primary site of disease for *radiation* therapy was the head and neck, followed by trachea, bronchus and lung, cervix uteri, breast, and esophagus. Frequency of squamous cell carcinoma was 38.0%; that of adenocarcinoma was 20.9%. Radical treatment was performed in 32.0% of patients in the first session, but this figure decreased to 24.7% for all sessions. There were many cases of secondary and primary palliative treatment, i.e., 31.8%. Radiotherapy was done in 70% of patients by megavoltage X-ray, with 9.4% treated by electron beam. Crude 5-year survival rates for each classification of malignant disease respective to the category of treatment policy from 1962 to 1978 were obtained. Among the radical treatment group, head and neck tumors, skin cancer, and Hodgkin's disease showed 5-year survival rates greater than 50%.

AB Through radiochemical analysis of voluntary tissue donations, the

U.S. Transuranium and Uranium *Registries* (USTR) are gaining improved understanding of the distribution and biokinetics of actinide elements in occupationally exposed persons. Evaluation of the first two whole-body contributions to the USTR revealed an inverse proportionality between actinide concentration and bone ash. The analysis of a whole body with significant ²⁴¹Am deposition indicated a significantly shorter half-time in liver and a greater fraction resident in the skeleton than predicted by existing models. Other studies with tissues obtained at autopsy suggest that existing biokinetic models for ²³⁸Pu and ²⁴¹Am and the currently accepted models and limits on intake, which use these models as their basis, may be inaccurately implying that revisions of existing safety standards may be necessary. Other studies of the *registries* are designed to evaluate in-vivo estimates of actinide deposition with those derived from postmortem tissue analysis, to compare results of animal experiments with human data, and to review histopathologic slides for tissue changes that might be attributable to exposure to transuranic elements. The implications of these recent findings and other work of the *registries* is discussed from the standpoint of this potential effect on biokinetic modeling, internal dose assessment, and safety standards and operational health physics practices. AB To assess the risk of *radiation-induced* cancer of the colon we studied 196 patients with a history of *radiation* treatment for cancer of the female genital system. After a median follow-up of 12.4 years (range 10-15 years) corresponding to 1172 patient-years, 94 (48%) patients were still alive. 84 (89%) of these patients were evaluated for a second primary cancer to the colon. In 38 (45%) colonoscopic examination was performed. 3 patients were found to have a second primary cancer to the colon compared with 0.32 expected (relative risk 9.3) on the basis of rates from the Zurich Tumor *Registry.* Due to partial long-term survival, patient non-compliance and non-feasibility of colonoscopic examination, only one fourth of all patients initially treated by radiotherapy for cancers of the female

genital system were suitable for colon screening. For these high risk women, colorectal tumor screening should be integrated into a gynecologic tumor follow-up. Author-abstract.

AB A case-control study was conducted to assess the risk factors associated with the development of a contralateral primary breast cancer among women who had had a first primary breast cancer. Hospital records were reviewed for 292 women with an incident contralateral breast cancer, diagnosed in one of eight hospitals between July 1, 1975 and December 31, 1983, and for a comparison group of 264 surviving unilateral breast cancer patients, previously diagnosed in the same hospitals. All subjects were identified through the records of the Connecticut Tumor *Registry.* Having an initial tumor containing lobular carcinoma was associated with an almost twofold increased risk of developing a contralateral cancer (aOR = 1.8; 95% CI: 1.0-3.5). Among those for whom a progesterone receptor assay was available, a positive assay was associated with an increased risk of a contralateral primary (aOR = 3.2; 95% CI: 1.0-9.5). AB blood type was also associated with an elevated risk, but this elevation was not statistically significant (aOR = 2.3; 95% CI: 0.7-7.7). Having received *radiation* treatment was not significantly associated with the risk of a contralateral primary (aOR = 0.9; 95% CI: 0.6-1.4), whereas chemotherapy treatment was associated with a significantly lowered risk (aOR = 0.3; 95% CI: 0.1-0.7). The association with chemotherapy appeared to be modified

by body build (ROR = 1.5; 95% CI: 1.0-2.3 for a 2.5-unit differential in Quetelet's index). Author-abstract.

AB Recent research has suggested that nonionizing *radiation* in the form of power-frequency magnetic fields may play some role in carcinogenesis in general and in acute nonlymphocytic leukemia in particular. Much of the epidemiologic evidence is preliminary in nature and the methods of previous studies have been criticized. In order to further evaluate this hypothesis, a population-based case-control study of adult acute nonlymphocytic leukemia and residential exposure to power-frequency magnetic fields was carried out in western Washington state. Analyses were based on 114 cases who were newly diagnosed from 1981 to 1984 and identified from a population-based cancer *registry,* and 133 controls who were chosen from the study area by random digit dialing. Magnetic field exposure was estimated from external electrical wiring configurations within 140 ft (42.7 m) of each subject's residence. In addition, magnetic fields were measured inside the subject's residence at the time of

interview. Neither the directly measured magnetic fields nor the surrogate values based on the wiring configurations were associated with acute nonlymphocytic leukemia. Author-abstract.

AB On the basis of information obtained from a population-based cancer *registry* in Sweden, male patients with breast cancer (n = 95) were found to have experienced significantly more brain concussions and

skull fractures than male patients with lung cancer (n = 383) or malignant lymphoma (n = 69). Other risk factors significantly associated with breast cancer among men were drug treatment associated with prolactin elevations, *radiation* treatment, family history of breast cancer among first-degree relatives, a history of gynecomastia, gonadal injury, and treatment for inguinal hernias. The results confirm some previously described risk factors for male breast cancer and suggest that events elevating plasma prolactin (e.g., drugs, brain concussions, and skull fractures) and events predisposing for inguinal hernias may be new risk factors for the disease. Using hospital charts is likely to underestimate exposure for different risk factors; therefore, the results need to be confirmed in studies that directly retrieve information. However, such studies are difficult or impossible to undertake in most countries because the disease is so rare. Author-abstract.

AB The frequency of secondary malignant neoplasms occurring in patients treated for Hodgkin's disease at the Royal Marsden Hospital between 1963 and 1978 is reported and the literature is reviewed. 730 patients were reviewed and 583 patients permanently resident in the United Kingdom were included in the analysis. The frequency of leukaemia and solid tumors was determined from age- and sex-corrected data from the South Thames Cancer *Registry.* Thirty-seven malignancies were recorded in 36 patients including 9 leukaemias, 10

lung cancers, 6 skin cancers and 2 non-Hodgkin's lymphoma, all of which were observed in significant excess. When all remaining sites are combined, there was a slight excess but no one site is individually significant. Author-abstract. 89 Refs.

LG English (EN).
AB The Late Effects Study Group (LESG) has collected 368 cases of second malignant neoplasms (SMN) in patients having been previously treated for a first malignancy during childhood. The most frequent first neoplasm is retinoblastoma, followed by Hodgkin's disease. The second neoplasms are essentially sarcomas mostly associated with *radiation* therapy. Leukemias are also frequent, apparently essentially induced by alkylating agents. The incidence of SMN depends on the primary and on the treatment given, thus it varies according to the studied cohorts. In the most recently analysed material of the LESG, the 20-year incidence was 8%. Children treated for a first neoplasm have an elevated risk of developing a SMN. Genetic predisposition may increase that risk. Author-abstract.

AB The records of all patients treated at UCLA with stage I through stage III testicular seminoma, diagnosed in 1956-1983, were reviewed. Histologic subtype, therapeutic protocol, survival, and the incidence of subsequent primary malignancies are examined in this presentation. The 10 year cause-specific survival is 93% for stage I and 70% for stage II patients. Of the four patients initially seen with stage III disease, three have achieved long-term disease-free survival after combined irradiation and chemotherapy. Irradiation of the whole pelvis was not associated with improved control for those patients with previous pelvic surgery. Four patients complained of gynecomastia after therapy, and since none of these patients had elevated human chorionic gonadotropin levels, the gynecomastia was attributed to gonadal failure. TI Mortality after radiotherapy for ringworm of the scalp.

SO Am-J-Epidemiol. 1988 Apr. 127(4). P 713-25.

JT AMERICAN JOURNAL OF EPIDEMIOLOGY.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB The mortality experience of 10,834 children treated with x-rays for ringworm of the scalp between 1948 and 1960, 10,834 matched comparison subjects, and 5,392 siblings was evaluated over an average follow-up period of 26 years. Mortality was ascertained by linking unique personal identification numbers of study subjects with the national death *registry.* Radiotherapy in childhood was associated with an increased risk of death due to tumors of the head and neck (relative risk (RR) = 3) and leukemia (RR = 2.3). No other causes of death were significantly elevated after irradiation. The excess of brain tumors (average intracranial dose = 150 rads) confirms that the central nervous system of the child is sensitive to the induction of cancers by *radiation.* The bone marrow dose averaged over the entire body was approximately 30 rad, and the estimated risk coefficient of 0.9 excess leukemias per million per year per rad is consistent with other studies of whole-body exposure. A significant excess of bone and soft tissue sarcomas (RR = 9) was also observed. The pattern of cancer risk over time was bimodal; an early peak due to excess leukemias occurred within a few years of exposure, whereas excesses of solid tumors were most apparent after about 15 years. Despite the excess of cancers among exposed persons, over 50% of the deaths in the entire study population were from external events, mainly accidents or events related to military service. An estimate of the total impact of radiogenic cancer after childhood irradiation will require additional years of observation since the population irradiated is just now entering the age ranges normally associated with high cancer risk. Author-abstract.

PT CLINICAL-TRIAL (CTR). JOURNAL-ARTICLE (ART).
LG English (EN).
AB Since its foundation in 1971, the RTOG has conducted a successful
clinical research program in head and neck mucosal squamous cell
carcinoma with 22 treatment protocols and one *registry* study which
combined have accumulated data on over 5,500 patients. The RTOG was
the first multicenter group to evaluate neoadjuvant chemotherapy
before definitive *radiation* with its methotrexate study. Although
the study was negative, RTOG has since conducted five pilot or phase
II studies of neoadjuvant or concurrent chemotherapy with *radiation*
therapy in patients with inoperable tumors. The last study showed
that *radiation* concurrent with cisplatin was tolerable with a
suggestion of increased antitumor effect. In patients with
potentially resectable tumors, RTOG has completed a pilot study of
combination chemotherapy administered either before or after the
surgery with radiotherapy. Based upon its findings, the treatment
sequence, surgery-chemotherapy-radiotherapy, was chosen as the
experimental arm for a new phase III study. This study was

subsequently adopted by the head and neck intergroup mechanism as its study (INT 0034/RTOG 8503). RTOG has investigated the optimal timing of radiotherapy with surgery. The 7303 study established that postoperative radiotherapy achieved significantly better locoregional control but not improved absolute survival. Approximately 30% of the patients on each arm failed to complete both modalities. Even when comparison is restricted to patients who completed both modalities, postoperative radiotherapy still produced the better locoregional control. Efforts to overcome the limitations imposed by tumor hypoxia through use of carbogen (95% O₂ and 5% CO₂) breathing or the radiosensitizer misonidazole during radiotherapy have been unsuccessful. In a phase I study, RTOG showed that 15 to 18 sessions of sensitized *radiation* can be safely delivered with the new radiosensitizer SR 2508 in contrast to only six such sessions with misonidazole. This promising radiosensitizer is now being tested in a phase III trial. RTOG has also investigated variations in fraction size, fraction number, and total *radiation* dose. In the 7102 study, split-course irradiation achieved equivalent antitumor results as compared to continuous daily irradiation but with less social alteration and cost to the patient. In the hyperfraction pilot study 7703, twice a day irradiation with 120 cGys up to 6,000 cGys proved to be tolerable.(ABSTRACT TRUNCATED AT 400 WORDS). Author-abstract.

AB To examine whether or not being born in the southern United States is
associated with an increased risk of ocular melanoma, the
distribution of State of birth of 763 patients (White, not of Spanish
origin) with ocular melanoma diagnosed between 1973 and 1984 and

identified by 9 population-based cancer *registries* participating in the Surveillance, Epidemiology, and End Results program, was compared to the distribution of State of birth of the underlying population of the regions served by these *registries.* The incidence of ocular melanoma among persons born in the southern United States was nearly the same as that among persons born in the north, after adjustment for age, sex, and residence at diagnosis (Incidence Ratio = 1.1, 95% C.I. 0.8, 1.5). Comparisons of the risk of ocular melanoma between persons born in States with high and low levels of solar *radiation* yielded similar results, and a trend with increasing solar *radiation* was observed only among females. These findings do not support the hypothesis that exposure to the sun early in life is a major risk factor for ocular melanoma. Author-abstract.

TI Second primary cancer after treatment for cervical cancer. Late effects after radiotherapy.

SO Cancer. 1988 Feb 15. 61(4). P 679-88.

JT CANCER.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Using data from the population-based Danish Cancer *Registry,* the relative risk (RR) of second primary cancer was assessed among 24,970 women with invasive cervical cancer (1943-1982) and 19,470 women with carcinoma in situ of the cervix. The analysis was stratified according to treatment with (+) and without (-) *radiation.* For all second primaries combined, a $RR+ = 1.1$ (95% confidence interval (CI) = 1.06-1.18) and a $RR- = 1.3$ (95% CI = 1.13-1.40) was observed after invasive cervical cancers and a $RR+ = 3.5$ (95% CI = 1.4-7.2) and $RR- = 1.1$ (95% CI = 0.7-1.6) following in situ cancer. The small overall excess of second primary cancer is accounted for by an increase of some cancers such as lung, bladder, and a concurrent decrease in others such as breast. Although not statistically different from nonirradiated, the RR increased with time since treatment among

irradiated invasive cervical cancer patients in organs close to and at intermediate distance from the cervix, reaching a maximum after 30 or more years of follow-up (RR = 1.9; 95% CI = 1.4-2.5). Altogether, for these sites an excess of 64 cases per 10,000 women per year were attributable to *radiation* among survivors of 30+ years. The highest risks among long-term survivors were observed for the following: other genital organs (RR = 5.8; 95% CI = 1.8-13.0) bladder (RR = 5.5; 95% CI = 2.8-9.5), connective tissue (RR = 3.3; 95% CI = 0.4-12.0), stomach (RR = 2.5; 95% CI = 1.1-4.7) and rectum (RR = 2.4; 95% CI = 1.1-4.6). A significant deficit of risk for breast cancer (RR = 0.7, 95% CI = 0.6-0.8) was observed for 10+ years, may be attributable to the effect of ovarian ablation by radiotherapy. It is speculated that the same effect also may explain the observed deficits of brain tumors (RR = 0.6; 95% CI = 0.4-1.0) and skin melanomas (RR = 0.6; 95% CI = 0.3-1.0). It is concluded that cancers attributable to *radiation,* apart from acute nonlymphocytic leukemias, tend to appear late (10 or more years after radiotherapy), and that the risk remains elevated for more than 30 years. Author-abstract.

 LG English (EN).
 AB The complete material of male breast cancer, 166 cases, reported to the Swedish Cancer *Registry* in 1958-1967 is described and analyzed concerning different prognostic parameters, treatment methods and survival. Age at diagnosis, axillary lymph node status and tumour size all had significant prognostic importance in a multivariate analysis with axillary lymph node status as the strongest factor.

Histologic malignancy grade was strongly correlated to axillary lymph node status and tumour size and thus to prognosis, but did not seem to be an independent prognostic factor. The primary treatment methods were quite heterogeneous and were obviously influenced by both age of the patient and clinical tumour status. No significant correlation was found between type of primary treatment and survival, but due to the retrospective nature of the study no definite conclusion could be drawn. Radical mastectomy seemed, however, to give fewer loco-regional recurrences than both modified radical mastectomy and simple mastectomy. Very few patients in the present series had received *radiation* therapy in adequate doses. The material gave some indications that orchiectomy might prolong survival in patients with recurrent or generalized disease.

TI *Radiation* dose and leukemia risk in patients treated for cancer of the cervix.

SO J-Natl-Cancer-Inst. 1987 Dec. 79(6). P 1295-311.

JT JOURNAL OF THE NATIONAL CANCER INSTITUTE.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB To quantify the risk of *radiation-induced* leukemia and provide further information on the nature of the relationship between dose and response, a case-control study was undertaken in a cohort of over 150,000 women with invasive cancer of the uterine cervix. The cases either were reported to one of 17 population-based cancer *registries* or were treated in any of 16 oncologic clinics in Canada, Europe, and the United States. Four controls were individually matched to each of 195 cases of leukemia on the basis of age and calendar year when diagnosed with cervical cancer and survival time. Leukemia diagnoses were verified by one hematologist. *Radiation* dose to active bone marrow was estimated by medical physicists on the basis of the

original radiotherapy records of study subjects. The risk of chronic lymphocytic leukemia, one of the few malignancies without evidence for an association with ionizing *radiation,* was not increased`relative risk (RR) = 1.03; n = 52:. However, for all other forms of leukemia taken together (n = 143), a twofold risk was evident (RR = 2.0; 90% confidence interval = 1.0-4.2). Risk increased with increasing *radiation* dose until average doses of about 400 rad (4 Gy) were reached and then decreased at higher doses. This pattern is consistent with experimental data for which the down-turn in risk at high doses has been interpreted as due to killing of potentially leukemic cells. The dose-response information was modeled with various RR functions, accounting for the nonhomogeneous distribution of *radiation* dose during radiotherapy. The local *radiation* doses to each of 14 bone marrow compartments for each patient were incorporated in the models, and the corresponding risks were summed. A good fit to the observed data was obtained with a linear-exponential function, which included a positive linear induction term and a negative exponential term. The estimate of the excess RR per rad was 0.9%, and the estimated RR at 100 rad (1 Gy) was 1.7. The model proposed in this study of risk proportional to mass exposed and of risk to an individual given by the sum of incremental risks to anatomic sites appears to be applicable to a wide range of dose distributions. Furthermore, the pattern of leukemia incidence associated with different levels of *radiation* dose is consistent with a model postulating increasing risk with increasing exposure, modified at high doses by increased frequency of cell death, which reduces risk. Author-abstract.

SO Jpn-J-Clin-Oncol. 1987 Dec. 17(4). P 293-302.

JT JAPANESE JOURNAL OF CLINICAL ONCOLOGY.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Using the data accumulated in the Osaka Cancer *Registry,* a cohort study was conducted on the occurrence of second primary cancers following the first breast cancer in females. Of the 9,503 breast cancer patients newly diagnosed in the period 1965-1982 who were followed up until the end of 1983 (average follow-up period, 5.7 years), 344 developed second cancers, whereas the expected number had been 211 (relative risk (RR) = 1.6; 95% confidence interval (CI) = 1.5-1.8). The increased risk was observed throughout the observation period, and was higher in patients of less than 45 years of age at diagnosis than in older women. Significant excess risks were found for second cancers of the opposite breast (RR = 4.2; 95% CI = 3.4-5.2), buccal cavity (RR = 3.6; 95% CI = 1.6-7.2), stomach (RR = 1.4; 95% CI = 1.2-1.8), colon (RR = 1.8; 95% CI = 1.1-2.1) and thyroid gland (RR = 3.2; 95% CI = 1.5-6.1). The effects of chemo- and radiotherapy administered for initial breast cancer on the increased risk of the above mentioned second cancers were also examined. These therapeutic measures were found not likely to be related to the excess risks for cancers of the buccal cavity, stomach and colon. For second cancer of the opposite breast, however, both chemotherapy and radiotherapy remained as possible risk factors. The effect of *radiation* was proposed as being a likely explanation for the excess risk of second thyroid cancer. Author-abstract.

TI Factors associated with the risk of second primary breast cancer: an
analysis of data from the Connecticut Tumor *Registry.*

SO J-Chronic-Dis. 1987. 40(11). P 1003-11.

JT JOURNAL OF CHRONIC DISEASES.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB To examine further the epidemiology of contralateral primary breast
cancer, a case-control analysis, utilizing information available from
the Connecticut Tumor *Registry,* was conducted. Recent cases of
second primary breast cancer were compared to control women who had
survived a first breast cancer but had not developed a second. Three
hundred and thirty eight incident cases of contralateral breast
cancer diagnosed between 1979 and 1982 were identified and compared
with an equal number of randomly selected controls and 336 controls

frequency matched to the cases on the basis of age at initial cancer diagnosis and the calendar time elapsing since that diagnosis. Risk of second primary breast cancer was found to be significantly elevated among women whose initial cancer was lobular carcinoma and during the first year following diagnosis of the initial primary. Additionally, for women initially treated with radiotherapy, risk of a contralateral primary increased for 10-14 years following treatment, after which it declined. Among young women, having never married was protective whereas the opposite was found among older women. These findings and the methods used are discussed in the context of the epidemiology of both contralateral and initial breast primaries. Author-abstract.

Western standards of medicine. Centers who have pioneered sustained maternal-neonatal assistance to Russia include Oakland Children's Hospital, Children's Hospital of the King's Daughter in Norfolk, Virginia, and the University of Maryland working in St. Petersburg, Moscow, and Kazan, respectively. During the past two years, I have been medical advisor to a World Learning project whose goal is to improve the health of women and children in the Sverdlovsk Region, a highly industrial polluted region lying on the eastern slope of the Ural mountains. The project is further supported by the Humanitarian Services Agency of the LDS church which has sponsored an exchange program of physicians and nurses between Yekaterinburg and hospitals in Utah to teach and inspire young talent in Russia to establish new standards of care for pregnant women and their newborns. This is led by Ronald Stoddard at Utah Valley Regional Medical Center and Steve Clark, Professor of Maternal/Fetal Medicine at the University of Utah. Not all is bleak in Russia. There is a good triage system in place, although neonatal transport systems are primitive in most areas. There is universal health coverage, and over 95% of babies are delivered in hospitals, usually by physicians. A massive effort to teach appropriate methods of resuscitation throughout the Sverdlovsk Region has already certified over 300 neonatologists, obstetricians, and midwives in the NRP course, with a measurable improvement in neonatal mortality in just one year. The Russian Health Department has recently mandated a protocol for infant resuscitation based on the NRP guidelines, and neonatologists from the Regional Children's Hospital in Yekaterinburg are now offering the NRP course to health care workers in neighboring regions. A national perinatal association has been established and is assisting the health department in developing neonatal care standards. the Neonatal Intensive Care Handbook (Goetzman/Wennberg, eds.) has been translated and extensively edited by neonatologists in Yekaterinburg to reflect Russian realities. It will be printed and distributed throughout Russia this fall and may facilitate establishing greatly needed care standards. Unlike other developing countries, the network for training physicians and caring for patients provides an opportunity to effect rapid change if the leaders have the vision to do so.

For me, watching the evolution of pediatric visionaries in Russia has been most gratifying, not to mention the large network of personal friends. The frustrations have resulted from the lack of political or financial support to effect change in some regions and the lack of well focused funding by American agencies and foundations to address the need in a cost-effective manner. I have received many inquiries from groups in the U.S. who would like to become involved in this medical revolution, but the minimal financial support required to create effective programs has been difficult to secure. An additional concern is the lack of communication between American groups currently involved in the CIS. Shared experiences, translated teaching material, effective and ineffective strategies, and follow-up evaluations would help all to avoid traps and to develop priorities. I would welcome hearing from any group currently participating or wishing to participate in maternal-infant programs in the CIS. Changing standards of care will ultimately require coordination of CIS physicians themselves, but communication among Americans committed to help would greatly facilitate that goal. For those wishing to network their efforts, I may be reached on the Internet: rpwennberg@ucdavis.edu or by phone/fax (916) 756-1985.

 TI [Around the **Semipalatinsk** proving grounds: the radioecological situation and the population radiation doses in **Semipalatinsk** Province (based on data from the report of the Interdepartmental Commission)]
 SO Med Radiol (Mosk) 1990 Dec;35(12):3-11
 JT MEDITSINSKAIA RADIOLOGIIA
 LA Rus For
 AB The paper represents some results of a joint commission, organized by the USSR Ministry of Health by order of the USSR Council of Ministers at public requests. The commission worked in the area neighbouring the proving ground at **Semipalatinsk** in the period of May-July 1988. A radiological situation there was investigated after underground nuclear testing on July 8, 1989. The results of measurements and archive data were used to estimate doses of radiation exposure of the population in the period of 1949 (nuclear testing on the ground and in the atmosphere) and in the period of underground testing, It was shown that in the period of 1949-1963 approximately 10,000 people received increased doses of external and internal irradiation. A high level of radiation-induced chromosome aberrations was noted among them. The highest effective equivalent doses of external and internal irradiation were received by the residents in the villages of Folon' (1.6 Gy during the first testing in 1949), Karaul (0.37 Gy), Sarzhai (0.20 Gy), Semenovka (0.02 Gy). The annual effective equivalent doses at that period did not exceed 0.0056 Gy (the highest value) for the **Semipalatinsk** residents. Proceeding from the values of collective doses probable long-term effects (malignant tumors) were assessed. Recommendations and conclusions of the commission are presented.

TI Diet and activity patterns of male and female co-workers: should
worksite *health* *promotion* programs assume homogeneity?

SO *Women-Health.* 1992. 19(4). P 31-54.

JT WOMEN AND *HEALTH.*

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB *Worksite* *health* *promotion* programs address the *health* education needs
of the average employee. Anthropometric measurements and 24h diet
and activity diaries collected from co-workers reveal that lifestyle
and subsequently, *health* education needs of men and women working for
the same employer, in the same environment and performing similar
tasks, may be different. In this study, males were marginally
overweight and obese; females were within recommended limits.
Although job related workloads were comparable, females were more
active (24hEE/FFM) outside the work place. Females spent more time
engaged in moderate weight-bearing domestic activities than did
males. These results question the effectiveness of *worksite* *health*
promotion program which ignore the different *health* education needs
of male and female employees. Author-abstract.

worksite sample.

SO *Health-Psychol.* 1992. 11(6). P 386-95.

JT *HEALTH* PSYCHOLOGY.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB We applied the model of the stages and processes of change to exercise adoption and maintenance. This model has shown promise in advancing theory and treatment of the addictions and other negative *health* behaviors, but there have been few systematic attempts to apply the model to positive *health* behaviors, such as exercise adoption. Questionnaires dealing with the stages and processes of exercise change were developed and administered to a sample of 1,172 participants in a *worksite* *health* *promotion* project. The sample was split randomly into halves for (a) initial model development and testing and (b) confirmatory measurement model testing. Additional model confirmation was obtained by examining the hierarchical structure of the processes of change and by conducting Stage x Process analyses. Results suggest that the underlying constructs derived from smoking cessation and other addictive behaviors can be generalized to exercise behavior. Understanding the stages and processes of exercise behavior change may yield important information for enhancing exercise adoption, adherence, and relapse prevention at both individual and public *health* levels. Author-abstract.

TI Managerial style and *health* *promotion* programs.

SO Soc-Sci-Med. 1993 Feb. 36(3). P 227-35.

JT SOCIAL SCIENCE AND MEDICINE.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Organizational correlates of *worksite* *health* *promotion* programs were isolated and interpreted within a diffusion of innovation framework. A sample of managers from California (U.S.A.) 500 organizations were interviewed via telephone on their corporate management styles and *health* care strategies. Organizational management style was found to be related to prevalence of *health* *promotion* programs and future plans for *health* *promotion* programs. Specifically, this study found that organizations with democratic management styles are more likely

to plan, adopt, and/or implement *worksite* *health* *promotion* programs when compared to organizations with authoritarian management styles. An additional contribution of this study was the development and validation of the Organizational Management Style (OMS) scale. These results have important theoretical and practical implications. For example, these findings explain why some organizations are more or less likely to adopt *health* *promotion* programs. Both diffusion of innovation and social control explanations are used to interpret the results. Author-abstract.

JT MILITARY MEDICINE.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB *Health* *promotion* programs are being offered in many segments of U.S.
society. Corporations find offering *health* *promotion* programs at the
worksite effective and cost-efficient. The U.S. military, following
a 1986 Department of Defense directive, has also developed *health*
promotion programs. At present, not all components of military
health *promotion* programs are being offered at the *worksite.*
Improved employee *health* and lower *health* care costs are objectives
sought by both the military and major corporations. Therefore, full
worksite implementation of all *health* *promotion* program components
will assist the military services in reaching their *health* goals.

 JT AMERICAN JOURNAL OF PREVENTIVE MEDICINE.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB The rapid expansion of *worksite* *health* *promotion* programs and the
 proliferation of service providers have resulted in increased concern
 about the quality of such programs. And while employers may view
 health *promotion* programs as a service to be purchased, in general,
 quality standards, price, and outcomes are less well established for
 primary prevention programs than for other medical services. This
 trend creates substantial potential for inappropriate expenditures,
 undermining the general credibility of such programs. Recognizing
 the limits of epidemiologic data and the potential for misuse of
 health *promotion* activities in the workplace, the California
 Department of *Health* Services (CDHS) undertook the development of
 guidelines for employers' use in assessing the quality of the
 numerous employee *health* *promotion* or chronic disease risk reduction
 programs available to them. To make the use of such programs as
 productive as possible, the CDHS developed recommendations in two
 main areas: (1) general recommendations for six fundamental program
 planning and development activities that underlie sound *health*
 promotion programs, and (2) specific criteria for seven types of
 health *promotion* programs commonly implemented in work settings.
 Optimally, *worksite-based* *health* *promotion* programs should be part of
 a comprehensive effort that provides for appropriate medical
 oversight, referral, and follow-up procedures. These programs should
 be complemented by appropriate changes in the work environment and in
 organizational policies. Programs should also include strategies to
 assist employees in initiating healthier behaviors and maintaining
 the new behaviors once they are established. Preventive medicine and
 occupational medicine practitioners and medical directors should be
 familiar with the issues addressed by these recommendations.

TI Cholesterol screening using the school as a *worksite.*
SO *J-Sch-Health.* 1992 Feb. 62(2). P 45-9.
JT JOURNAL OF SCHOOL *HEALTH.*
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB This article illustrates the appropriateness of the school as a
worksite for *health* *promotion* programs and demonstrates how
cholesterol screening is an effective tool to introduce such a
program into a school system. Of 1,639 employees, 1,217 elected to
have their cholesterol measured (74% response rate). Forty-five
percent had elevated cholesterol according to the NIH Consensus
Panel. Of these, 12% were in the "high" category (greater than or
equal to 240 mg/dl) while 33% had levels that placed them in the
"borderline high" risk category (200-239 mg/dl). Cholesterol
screening can be incorporated easily into most school systems due to
the presence of nursing staff and *health* educators. Systematic
planning is essential for success and must include a counseling and
educational intervention coupled with an active referral and
follow-up program. This type of screening should be part of a
multicomponent *health* *promotion* program. Author-abstract.

JT JOURNAL OF COMMUNITY *HEALTH.*
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB A survey of *worksite* *health* *promotion* activities in nine areas of
health was conducted in four Midwest cities--Winona and St. Cloud,
MN; Eau Claire, WI and Sioux Falls, SD to determine how many
worksites are involved in these activities; how many different kinds
of programs they offer; and whether or not *worksite* involvement is
growing in these areas of *health.* All *worksites* with over 100
employees were surveyed with a completion rate of 96% for eligible
worksites. Comparing program offerings at *worksites* with such
offerings by other community providers, we find *worksites* provide 40%
of the total of such programs to adults. They tend to operate most
programs independently of other community providers. Exercise and
smoking cessation programs are most commonly offered. *Worksites* in
the four communities significantly differed in the number of exercise
program options offered and in the prevalence of *worksite* involvement
in home, personal and drivers' safety programs. Compared to national
survey results, *worksites* in these Midwest cities show a lower level
of participation in heart disease and cancer screening activities.
There is a high rate of dropout among current providers of heart
disease screening activities and few nonproviders are initiating
programs. Program initiation among nonproviders is highest in
smoking cessation, weight loss and nutrition. Program growth among
current providers is high in the areas of chemical dependency,
exercise and personal, home and drivers' safety. Author-abstract.

JT AMERICAN JOURNAL OF PUBLIC *HEALTH.*

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB Using 1,004 subjects enrolled in a *worksite* *health* *promotion* program, this report evaluated the validity of a single question about participation in regular exercise. Measured at baseline, this one question had a significant age-adjusted association with body mass index (p less than 0.0001 in women and p = 0.001 in men), HDL cholesterol (p less than 0.0001 in women), and oxygen capacity (p = 0.0007 in women and p = 0.002 in men). Thus, one self-reported question can provide useful information about who is and who is not participating in regular exercise. The potential validity of a single exercise question is particularly relevant in complex epidemiologic studies where lengthy questionnaires highlight the importance of brief instruments. JT *HEALTH* EDUCATION QUARTERLY.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB Although *worksite* *health* *promotion* programs have proliferated, little
is known about the population they reach. This study of employees of
a large utility company compared whether the same characteristics
which predict recruitment also predict extended participation. The
study also prospectively assessed how risk factors are related to
employees' on-going extended participation. The findings demonstrate
that sociodemographic predictors of recruitment are almost mirror
images of the predictors of extended participation. Over time
employees who are at higher risk for cardiovascular disease
participated in on-going sessions less frequently. Data suggest that
referral to targeted sessions does not result in higher rates of
attendance by employees with a particular risk factor, although there
is no evidence of selective avoidance. Organizational influences on
participation evident from the beginning are sustained through four
sessions. Programs targeting higher risk employees nested within
worksite-wide programs may be useful to increase the extended
participation of individuals at elevated risk for heart disease.

AB Corporations are beginning to examine exactly who is responding to *health* *promotion* programs offered at the *worksite.* Most findings indicate that those employees using most of the *health* care dollars are the least involved in *health* promoting efforts. When assessing why certain employees choose not to participate, application of a *health* *promotion* model will identify direct and indirect factors associated with this choice. Based on factors identified in the *health* *promotion* model, wellness programs are designed to fit the employees' level of readiness to adopt healthy behaviors. The three program levels build upon each other to achieve *health* *promotion.* The occupational *health* nurse has the skills necessary to identify this population which continues to live unhealthy lifestyles. The overall goal is to increase their participation in *health* *promotion.* This may be achieved by identifying their needs and designing programs accordingly. Author-abstract.

 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB As part of the National *Worksite* *Health* *Promotion* Survey, a representative sample of *worksites* across the United States with 50 or more employees was asked about the presence and types of activities they sponsor to promote smoking control. Smoking control activities were reported at 35.6% (CI 32.6-38.6) of all *worksites.* Among *worksites* with any smoking control activity 76.5% (CI 71.7-81.3) had a formal policy restricting smoking, 54.3% (CI 48.7-59.9) provided information about the harmful effects of smoking, and 49.6% (CI 44.4-54.8) made self-help materials available. Individual counseling, group classes, workshops, follow-up support and reinforcement, or special events were available at 38.3% (CI 32.9-43.7) of *worksites* with any smoking control activities. Frequency increased as *worksite* size increased, with large frequency differences between the smallest and largest *worksites.* Smoking policies were most often put into effect to protect the *health* of nonsmokers (39.1%, CI 32.1-46.1) or to comply with regulations or laws (38.2%, CI 32.2-44.2). The most frequently reported benefit to the *worksite* of smoking control activities was improved employee *health* (35%, CI 26.2-43.8). Benefits were considered to outweigh the cost of activities at 36% (CI 29.6-42.4) of *worksites,* although 41.7%

(CI 34.7-48.7) said it was too soon to gauge the relative size of costs and benefits. Author-abstract.

 TI The flow-ratio index. An approach for measuring the influence of age
 and cigarette smoking on maximum expiratory flow-volume curve
 configuration.
 SO Chest. 1990 Sep. 98(3). P 643-6.
 JT CHEST.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB A forced expiratory flow ratio, derived from the average slope of the
 maximum expiratory flow-volume (MEFV) curve over a specified volume
 interval, was examined in healthy asymptomatic cigarette smokers and
 nonsmokers. This index was developed to have the properties that it
 would be (1) simple to calculate, (2) less effort dependent than
 indices that incorporate peak flow, and (3) free of influence from
 the configurational detail and noise frequently occurring at higher
 lung volumes on MEFV curves. Forced expired vital capacity maneuvers
 were performed by participants in a *worksite* *health* *promotion*
 program. Data from asymptomatic individuals with normal pulmonary
 function were analyzed for 49 cigarette smokers and 52 nonsmokers; 25
 individuals had MEFV curves collected twice over a one-year interval.
 The ratio of flow derived from an average MEFV slope to instantaneous
 flow was calculated over the lower half of the vital capacity. Flow
 ratios were expressed as a percentage of the instantaneous flow at 75
 percent of the expired vital capacity (FR75). This ratio was
 reproducible from year 1 to year 2 ($r = 0.86$, p less than 0.0001).
 Furthermore, the FR75 was well correlated with age among cigarette
 smokers and nonsmokers ($r = 0.68$ and 0.63 respectively). The slope
 of the least squares regression equation relating FR75 to age was
 significantly greater among smokers than nonsmokers (2.90 percent per
 year vs. 1.73 percent per year, p less than 0.025). While there was

a significant interactive influence of age and total pack-years on the FR75 ($F = 2.91$, $p = 0.02$), this index did not differ systematically by gender. We conclude that the FR25 is a more sensitive index of altered lung function in cigarette smokers than are results of conventional pulmonary function. Author-abstract.

JT JOURNAL OF OCCUPATIONAL MEDICINE.

PT CLINICAL-TRIAL (CTR). JOURNAL-ARTICLE (ART). MULTICENTER-STUDY (MUL).

LG English (EN).

AB As workplaces increasingly adopt proactive programs directed toward employee *health* issues, the interrelation between different programs becomes an important issue. Of interest here is the "synergy" in patterns of program adoption between employee assistance programs (EAPs) and *health* *promotion* activities (HPAs). We utilize the 1985 National Survey of *Worksite* *Health* *Promotion* Activities (N = 1358) for analyses of the dual presence of EAPs and HPAs, and in multivariate analyses we consider factors affecting such dual presence. The data suggest that synergy occurs, with EAP adoption appearing to influence HPA adoption to a greater extent than the reverse. In multivariate analyses, synergy is confirmed by the finding that, among a variety of relevant organizational characteristics, EAP presence and HPA presence are the best

predictors of each other's presence. The analyses also indicate that there is minimal commonality in program ingredients across organizations reporting the presence of HPAs. Implications of the data for the future development of these two programming strategies are discussed. Author-abstract.

AB Smoking control is a key element of *worksite* *health* *promotion.* This three-stage study in a large state human services agency included a baseline survey, an assessment of the effects of competition on recruitment to a self-help cessation program, and examination of the outcome of the cessation program. In stage 1, scales for measuring smoking-related attitudes and the social environment were developed and used to study norms for smoking. Regression analysis was used to ascertain correlates of smokers' intentions to quit and to join a self-help program and non-smoker assertiveness. In stage 2, an evaluation using a quasi-experimental design indicated that competition was moderately effective in increasing the recruitment of all employees to the Great American Smoke-Out (70 vs. 17%) and of smokers to a self-help cessation program (28 vs. 6%). In stage 3, the self-reported quit rate at the end of the program was 28% and the biochemically-verified six months' cessation rate was 7%. Efforts are needed to strengthen, using ethical means, the norms for not smoking at the *worksite* and to increase both the recruitment to and the effectiveness of smoking cessation programs. Author-abstract.

 TI The need for a more holistic *health* care system.
 SO AAOHN-J. 1989 Dec. 37(12). P 518-25.
 JT AAOHN JOURNAL.
 PT JOURNAL-ARTICLE (ART).
 LG English (EN).
 AB As a result of the evolution of *health* problems in the United States, the current *health* care system must change its focus from the traditional biomedical model to a holistic *health* oriented model. The holistic *health* oriented system is based on the enhancement and maintenance of *health*,* not on the cure of disease. Given positive research findings concerning the *health* and cost benefits of *worksite* *health* *promotion* programs, it appears that industry, along with third party payers, nurses, and other *health* care professionals, could alter the emphasis and direction of *health* care. The *worksite* provides an ideal setting for the development of holistic programs. The occupational *health* nurse, whose role involves *health* *promotion*,* *health* protection, environmental screening, and illness intervention, is in the best position to work with management in developing *health* *promotion* programs. Author-abstract.

AB A decision-analytic model was developed to project the future effects
of selected *worksite* *health* *promotion* activities on employees'
likelihood of chronic disease and injury and on employer costs due to
illness. The model employed a conservative set of assumptions and a
limited five-year time frame. Under these assumptions, hypertension
control and seat belt campaigns prevent a substantial amount of
illness, injury, and death. Sensitivity analysis indicates that
these two programs pay for themselves and under some conditions show
a modest savings to the employer. Under some conditions, smoking
cessation programs pay for themselves, preventing a modest amount of
illness and death. Cholesterol reduction by behavioral means does
not pay for itself under these assumptions. These findings imply
priorities in prevention for employer and employee alike.

AB Data from the National Survey of *Worksite* *Health* *Promotion* Activities
include information about *health* risk assessment (HRA) activities
available at private sector *worksites* in the United States. HRA

activities were found at 29.5% of all *worksites.* Of those *worksites,* 24% provided HRA questionnaires and 77.4% provided periodic *health/physical* examinations. Screening tests provided as part of the *health/physical* exams included blood pressure screening (55.4%), cancer screening (19.5%), blood tests for cholesterol (28.3%) and sugar (39%), and tests of physical fitness (15.1%). In most cases, the frequency increased as *worksite* size increased, regional variations were small, and there was significant variation among different industry types. HRA activities were overrepresented at *worksites* where the majority of workers were women, over 30 years of age, not blue collar, and not represented by a union. On-site *health* personnel increased the likelihood of the presence of HRA activities. At 85% of the *worksites* with HRA activities all permanent employees were eligible. The full costs of screening were paid by 87.9% of the *worksites,* activities were held on company time at 74.5%, and time off to participate was available at 78.2% of *worksites.* The most commonly mentioned benefit of HRA activities was improved employee *health* (47.1%). Other *health* *promotion* activities frequently found in association with HRA activities were smoking cessation (54.1%), care and prevention of back pain (50.8%), and stress management (49.6%). AB Despite their growing popularity, *worksite* *health-promotion* programs
have generally been characterized as having low participation rates,
high attrition rates, and modest outcomes. This investigation
identified the predictors of participation, attrition, and outcome of
worksite smoking-cessation program. Subjects were regular cigarette
smokers recruited from two *worksites.* Of 66 eligible smokers in the
two *worksites,* 44 (67%) agreed to participate in the program.
Fifty-five percent (24 of 44) of these completed the program. Of
those completing the program, 29% had quit smoking by posttest and
17% were abstinent at the 6-month follow-up. Results indicated that
a different set of variables predicted participation, attrition, and
outcome. The significant predictors of smokers who participated were
the length of cessation in previous abstinence attempts, the number
of years they smoked, and the belief regarding personal vulnerability
in contracting a smoking-related disease. Levels of pretest carbon
monoxide along with attitudes regarding the adoption of smoking
restrictions in the *worksite* predicted attrition. Posttest cessation
was related to nicotine levels of cigarette brand smoked at pretest
and pretest beliefs regarding postcessation weight gain. Abstinence
at the 6-month follow-up was predicted by the number of co-workers
who smoked and pretest concerns related to postcessation weight gain.
The results are discussed in terms of future evaluation and
intervention efforts. Author-abstract.

AB The first National Survey of *Worksite* *Health* *Promotion* Activities surveyed a random sample of all private sector *worksites* with 50 or more employees, stratified by number of employers, geographic location, and type of industry. The 1,358 completed interviews constituted a response rate of 83.1 per cent. Of responding *worksites* 65.5 per cent had one or more areas of *health* *promotion* activity with slightly more than 50 per cent of activities initiated within the previous five years. Overall prevalence by type of activity included *health* risk assessment (29.5 per cent), smoking cessation (35.6 per cent), blood pressure control and treatment (16.5 per cent), exercise/fitness (22.1 per cent), weight control (14.7 per cent), nutrition education (16.8 per cent), stress management (26.6 per cent), back problem prevention and care (28.5 per cent), and off-the-job accident prevention (19.8 per cent). Mean number of activities across all *worksites* was 2.1 and for *worksites* with

activities, 3.2. Activity frequency increased with *worksite* size, was highest in the western region (2.34) and lowest in the northeast (1.96), and varied considerably by industry type. The majority of *worksites* paid the entire cost of these activities.

AB Few companies or organizations involved in *health* *promotion* have
addressed the major question of whether they are reaching the
employees with the greatest *health* needs or those who could benefit

most from these efforts. The popular view that only individuals who are already physically fit and healthy participate in *worksite* wellness programs was critically examined. Data from 523 survey respondents at the University of Oregon were analyzed to determine whether employees differed on *health-related* characteristics and their interest in attending a *worksite* *health* *promotion* program. Comparisons between program participant "intenders" and "nonintenders" revealed that both groups had similar lifestyle habits, preventive *health* practices, and *health* status profiles. Significant differences were more related to age and perceptions about their physical and emotional *health* status. Implications for *health* risk reduction program planning in the work setting are discussed. Author-abstract.

JT SOCIAL SCIENCE AND MEDICINE.
PT JOURNAL-ARTICLE (ART).
LG English (EN).
AB One method of increasing the cost-effectiveness of *worksite* *health*
promotion programs is to develop programs that also have an impact on
risk factors of family members and friends of the employees. In this
study, 41 wives of fire fighters were interviewed concerning changes
the fire fighters and they had made in their *health* habits--exercise,
weight, and consumption of fats, fruits/vegetables, and cereal/whole
grain breads--in the previous year. Thirty-two were wives of fire
fighters who had received a *worksite* *health* *promotion* program and
nine were wives of fire fighters who had not yet received the
program. Findings of our exploratory study strongly suggest that
wives of fire fighters who received information were more aware of
the program (93% vs 56%), had greater exposure to the written diet
plan (72% vs 11%) and guide to high fat foods (72% vs 0%) than
controls. Furthermore, the intervention led to changes in the fire
fighters' *health* habits that were reported by the wives. No
significant changes in the wives' *health* habits occurred as a result
of the intervention, although the changes were in the predicted
direction in every category; changes by the wives were, however,
related to changes by fire fighters. Involvement of the fire
fighters in the preparation of meals and sharing of information from
the intervention program by the participant with the wife, were
related to change in *health* habits of the wives.(ABSTRACT TRUNCATED

AB A model of intentional *health-related* behaviors was tested to predict men's and women's participation in six *worksite* *health* *promotion* programs. The model was best at predicting participation in programs that treat unhealthy conditions or behaviors. It was least successful at predicting participation in programs than can appeal to both those with *'health* risks' and to *health* 'maximizers'. Women had higher rates of participation than men in three of the four 'treatment' programs, and they participated in more programs. In every program type, the factors that influence women's participation were different from those affecting men; and women with children showed different patterns of influence from women without children. The patterns of influence are consistent with two sources for women's greater concern with treating poor *health:* their nurturant role responsibilities, and a particular emphasis by the medical profession on women and women's concerns. AB This paper uses data from an employee *health* *promotion* project for government employees to examine initial *health* practices and their relationship to social and demographic variables. It then uses data collected one year later to examine changes in *health* behaviors and to try to explain what types of people are most likely to undertake *health* behavior changes in a year, within the context of a *worksite* *health* *promotion* project. Most people in this sample of employees do make positive changes in *health* habits in at least one of the following areas: smoking, seatbelt usage, diet, exercise, alcohol usage. While a variety of different social and demographic variables are important in explaining initial differences in *health* practices, these same variables along with measures of personal efficacy and job stress are poor predictors of whether people change their *health* behavior over a year. Future research might usefully focus on more detailed collection of qualitative data to help understand what factors motivate people to change *health* behavior. Future survey approaches may then incorporate broader and more diverse categories of explanatory variables into regression models. Author-abstract.

TI Corporate characteristics and *worksite* *health* *promotion* programs: survey findings from Fortune 500 companies.

SO Soc-Sci-Med. 1988. 26(5). P 491-501.

JT SOCIAL SCIENCE AND MEDICINE.

PT JOURNAL-ARTICLE (ART).

LG English (EN).

AB A study was carried out to assess the nature and extent of *worksite* *health* *promotion* programs in Fortune 500 companies. Growth and interest in *worksite* *health* *promotion* continues at a remarkable rate. Fortune 500 firms are a good barometer of the state of the art of programs in work settings because these companies have large numbers of employees, an interest in cost savings, and expertise to invest in innovative efforts. Data collection consisted of questionnaires sent

to the medical officer or Chief Executive Officer of all companies appearing on the 1984 Fortune 500 list. The following issues were addressed: whether companies offered *worksite* programs; what *health* *promotion* activities were provided in their programs; whether organizations had plans to start up or expand programs; what organizational support existed for programs (i.e. who pays, on whose time employees participate, when activities are offered, and what types of personnel are hired to staff programs); and whether these companies applied needs assessments, evaluation and cost analysis in their programs. Differences in these characteristics were examined in relation to the organizational variables of size (number of employees), Fortune 500 rank and type of industry (low-technology versus high-technology). The response rate for the survey was 49.4% (n = 247). Results of the study indicate a high level of *health* *promotion* activity in Fortune 500 firms. Out of the total group of respondents, two-thirds (n = 164) report having *worksite* programs and two-thirds of organizations with programs have plans to expand their *health* *promotion* offerings. One-third of responding organizations without programs planned to initiate them. The *health* *promotion* activities provided are numerous and varied, and within units that have programs rates of employee eligibility are reported to be high. However, the participation rates reported are appreciably lower. It is of special interest that, in general, the higher ranked, larger and high-technology companies are more likely to have programs; offer more activities in programs; have plans for program expansion; use a model of sharing costs of, and time to participate in program activities; make greater use of *health* professionals; and utilize more often needs assessment, evaluation and cost analysis techniques. The results of this study underscore the importance of examining a broad constellation of factors surrounding *worksite* programs. Given the organizational literature reviewed, it is likely that the characteristics of Fortune 500 programs documented here will serve as models for programs in midsize and smaller companies.

TI Passive smoking and lung cancer in nonsmoking women.

SO *Am-J-Public-Health.* 1992 Nov. 82(11). P 1525-30.

JT AMERICAN JOURNAL OF PUBLIC *HEALTH.*

AB OBJECTIVES. The causes of lung cancer among nonsmokers are not clearly understood. To further evaluate the relation between passive smoke exposure and lung cancer in nonsmoking women, we conducted a population-based, case-control study. METHODS. Case patients (n = 618), identified through the Missouri Cancer Registry for the period 1986 through 1991, included 432 lifetime nonsmokers and 186 ex-smokers who had stopped at least 15 years before diagnosis or who had smoked for less than 1 pack-year. Control subjects (n = 1402) were selected from driver's license and Medicare files. RESULTS. No increased risk of lung cancer was associated with childhood passive smoke exposure. Adulthood analyses showed an increased lung cancer risk for lifetime nonsmokers with exposure of more than 40 pack-years from all household members (odds ratio `OR: = 1.3; 95% confidence interval `CI: = 1.0, 1.8) or from spouses only (OR = 1.3; 95% CI = 1.0, 1.7). When the time-weighted product of pack-years and average hours exposed per day was considered, a 30% excess risk was shown at the highest quartile of exposure among lifetime nonsmokers. CONCLUSIONS. Ours and other recent studies suggest a small but consistent increased risk of lung cancer from passive smoking. Comprehensive actions to limit smoking in public places and *worksites* are well-advised.

TI *Worksite* nutrition education can lower total cholesterol levels and promote weight loss among police department employees.

SO J-Am-Diet-Assoc. 1992 Nov. 92(11). P 1382-4.

JT JOURNAL OF THE AMERICAN DIETETIC ASSOCIATION.

AB Individuals who work in law enforcement careers are often subjected to stress that can result in *health* and emotional disorders. Many police departments have begun to offer wellness programs to support their employees. This pilot study designed and implemented a nutrition education component for an existing police department wellness program. Twenty-eight subjects completed the 12-month study that included nutrition counseling, seminars on nutrition and eating behaviors, and monitoring of weight and blood lipid levels. There was a significant group trend for decreased weight and lower total cholesterol levels. Results of the study led to the development of *health* policy standards for the Austin (Tex) Police Department.

Wellness programs that involve registered dietitians can result in weight loss and lower cholesterol levels for employees in high-stress occupations as well as changes in departmental policy.

TI *Health* *promotion--a* further field to conquer.

SO Singapore-Med-J. 1992 Aug. 33(4). P 341-6.

JT SINGAPORE MEDICAL JOURNAL.

AB We examine some of the interpretations of *health* *promotion.* A brief review of the effectiveness of some *health* *promotion* programmes in the community and at the *worksite* in the United States is also presented in view of the similarity of its disease pattern with Singapore. We recommend the following strategies for the practice of *health* *promotion* in Singapore: formulation of clearly defined goals; intersectoral collaboration and community participation. Tanahill's model based on the overlapping spheres of *health* education, disease prevention and *health* protection is useful in identifying key groups and their roles in *health* *promotion.* Green's PROCEED-PRECEDE planning framework which identifies the various behavioural and environmental factors affecting *health* can help in deriving a highly focused subset of factors as targets for intervention. Research in *health* *promotion* should focus on compliance studies on healthy lifestyle regimens, and qualitative and quantitative evaluative studies on process and outcomes of different interventions.

TI *Worksite* *health* *promotion:* rationale for military implementation.

SO Mil-Med. 1992 Aug. 157(8). P 426-30.

JT MILITARY MEDICINE.

AB *Health* *promotion* programs are being offered in many segments of U.S. society. Corporations find offering *health* *promotion* programs at the *worksite* effective and cost-efficient. The U.S. military, following a 1986 Department of Defense directive, has also developed *health* *promotion* programs. At present, not all components of military *health* *promotion* programs are being offered at the *worksite.* Improved employee *health* and lower *health* care costs are objectives sought by both the military and major corporations. Therefore, full *worksite* implementation of all *health* *promotion* program components will assist the military services in reaching their *health* goals.

AU Lusk-S-L.

TI Selling *health* *promotion* programs: recommendations for occupational *health* nurses.

SO AAOHN-J. 1992 Sep. 40(9). P 414-8.

JT AAOHN JOURNAL.

AB 1. Although some suggest that *health* *promotion* programs should not

be conducted in the workplace, there is generally strong support for workplace programs by both the public and private sectors. 2. Many published reports of cost savings attributed to *health* *promotion* programs are available. The calculations of cost savings contain many flaws and generally do not reflect a comprehensive analysis of all costs associated with programs, especially those associated with changes in death rates and longevity. 3. Specific recommendations for occupational *health* nurses include: analysis of the corporate situation; integration of programs with occupational *health* and safety activities; involvement of all levels of workers in planning and promoting the programs; evaluation through employee participation and satisfaction, not by cost benefit analysis; and consideration of offering programs to family members. 4. Nursing as a whole should provide leadership for implementing programs to promote *health* and prevent disease. The *worksite* offers unique opportunities for occupational *health* nurses to implement the Healthy People 2000 objectives to enhance the *health* of working adults.

TI Quality assessment in *worksite* *health* *promotion*.*

SO Am-J-Prev-Med. 1992 Mar-Apr. 8(2). P 123-7.

JT AMERICAN JOURNAL OF PREVENTIVE MEDICINE.

AB The rapid expansion of *worksite* *health* *promotion* programs and the proliferation of service providers have resulted in increased concern about the quality of such programs. And while employers may view *health* *promotion* programs as a service to be purchased, in general, quality standards, price, and outcomes are less well established for primary prevention programs than for other medical services. This trend creates substantial potential for inappropriate expenditures, undermining the general credibility of such programs. Recognizing the limits of epidemiologic data and the potential for misuse of *health* *promotion* activities in the workplace, the California Department of *Health* Services (CDHS) undertook the development of guidelines for employers' use in assessing the quality of the

numerous employee *health* *promotion* or chronic disease risk reduction programs available to them. To make the use of such programs as productive as possible, the CDHS developed recommendations in two main areas: (1) general recommendations for six fundamental program planning and development activities that underlie sound *health* *promotion* programs, and (2) specific criteria for seven types of *health* *promotion* programs commonly implemented in work settings. Optimally, *worksite-based* *health* *promotion* programs should be part of a comprehensive effort that provides for appropriate medical oversight, referral, and follow-up procedures. These programs should be complemented by appropriate changes in the work environment and in organizational policies. Programs should also include strategies to assist employees in initiating healthier behaviors and maintaining the new behaviors once they are established. Preventive medicine and occupational medicine practitioners and medical directors should be familiar with the issues addressed by these recommendations.

TI Coronary risk factor behavior change in hospital personnel following
a screening program.

SO Am-J-Prev-Med. 1992 Mar-Apr. 8(2). P 115-22.

JT AMERICAN JOURNAL OF PREVENTIVE MEDICINE.

AB We conducted a *worksite* cardiovascular disease (CVD) awareness and education program at a large medical center. The program consisted of employee screening for blood pressure and total serum cholesterol level, dissemination of information on risk factors for CVD, counseling on behavior change, and evaluation of the screening event as an educational tool. During this five-day event, 2,284 employees were screened for hypertension and hypercholesterolemia. Consenting employees completed a *health* risk appraisal survey (n = 2,255) and received counseling on their results and CVD risk factors. Appropriate referrals to *health* care professionals and educational programs were made according to national guidelines. We developed three-month and six-month follow-up surveys and distributed them to all participating employees. The analysis of these data suggests some positive impact upon behavior change within this employee population. In addition to the two follow-up surveys, we held a second blood pressure and serum cholesterol screening eight months after the initial screening. Comparison of the levels taken from both screenings (n = 234) suggests that *worksite* screening programs may influence significant serum cholesterol and blood pressure reductions in high-risk employees. Author-abstract.

TI Impact of a community *health* *promotion* program on existing
organizations: the Minnesota Heart *Health* Program.

SO Soc-Sci-Med. 1992 Mar. 34(6). P 639-48.

JT SOCIAL SCIENCE AND MEDICINE.

AB A community organization strategy was used in the delivery of *health* education programs by the Minnesota Heart *Health* Program (MHHP). The effectiveness of the approach was evaluated to determine whether an enhanced *health* *promotion* delivery system had developed in MHHP communities by the end of the intervention period or whether the intervention had suppressed community efforts. 'Social connectedness' among providers, as measured by *health* *promotion* network size, also was expected to be higher in intervention communities. Six Midwestern communities were studied: the MHHP communities of Mankato, MN and Fargo, ND--Moorhead, MN with two matched comparison communities for each (Winona, MN, St Cloud, MN and Eau Claire, WI, Sioux Falls, SD). Nine areas of *health* *promotion* were assessed, including the five heart disease risk factor areas where education campaigns had been implemented (smoking cessation, weight loss, eating patterns, exercise, and heart disease education and screening) and four other areas where community programs are common (chemical dependency; home, personal and drivers' safety; stress management; and cancer education and screening). Indicators of the *health* *promotion* delivery system were developed (program options and program participation), and data were collected in separate surveys of 438 community organization providers and 320 larger *worksites* in the six communities. Results showed no suppression of *health* *promotion* delivery systems in MHHP communities. Instead, the survey of larger *worksites* showed that there was greater participation in heart disease *health* *promotion* and greater 'social connectedness' among *worksites* in both intervention communities. Also, there were more heart disease *health* *promotion* programs in the larger intervention community of Fargo-Moorhead. In the community organization survey, results favored the larger intervention community over its comparison communities in heart disease *health* *promotion* program options and in 'social connectedness' but not in program participation. However, survey results favored one of the comparison communities (Winona) over the smaller intervention community (Mankato) on all indicators in this survey. The greater impact of the MHHP intervention at *worksites* suggests that institutionalization may be more likely in stable organizations whose current needs and interests fit the goals of the intervention activity.

TI Cholesterol screening using the school as a *worksite.*

SO *J-Sch-Health.* 1992 Feb. 62(2). P 45-9.

JT JOURNAL OF SCHOOL *HEALTH.*

AB This article illustrates the appropriateness of the school as a *worksite* for *health* *promotion* programs and demonstrates how cholesterol screening is an effective tool to introduce such a program into a school system. Of 1,639 employees, 1,217 elected to

have their cholesterol measured (74% response rate). Forty-five percent had elevated cholesterol according to the NIH Consensus Panel. Of these, 12% were in the "high" category (greater than or equal to 240 mg/dl) while 33% had levels that placed them in the "borderline high" risk category (200-239 mg/dl). Cholesterol screening can be incorporated easily into most school systems due to the presence of nursing staff and *health* educators. Systematic planning is essential for success and must include a counseling and educational intervention coupled with an active referral and follow-up program. This type of screening should be part of a multicomponent *health* *promotion* program.

TI A profile of *health* risks among blue-collar workers.

SO J-Occup-Med. 1992 Jan. 34(1). P 61-8.

JT JOURNAL OF OCCUPATIONAL MEDICINE.

AB Despite national objectives for extending *health* *promotion* programs to blue-collar workers and to small work sites, baseline behavior information for planning such programs is lacking. This study seeks to describe the *health* risks and norms specific to a population of male, blue-collar gas pipeline workers in remote sites. These workers (n = 395) completed a *health* risk appraisal and a *"health* gauge" survey designed to measure nutrition, physical activity, tobacco use, participatory patterns in *health-enhancing* activities, group norms, and change efforts. Selected behaviors were similar to those of other Texas men (eg, smoking 27% versus 26%) although others were not (eg, smokeless tobacco 18% versus 8%). Multivariate analysis confirmed the relationship of friends' behavior patterns, risk-taking, and interpersonal experience to four lifestyle *health* behaviors. With 75% or more of workers expressing an interest in various programs, the findings suggest that programming for this population can be successful if tailored to current behaviors and the *worksite* culture.

TI *Worksite* and Community *Health* *Promotion/Risk* Reduction Project--Virginia, 1987-1991.

SO MMWR-Morb-Mortal-Wkly-Rep. 1992 Jan 31. 41(4). P 55-7.

JT MMWR. MORBIDITY AND MORTALITY WEEKLY REPORT.

AB Because cardiovascular disease (CVD) is a leading cause of premature disability and death in the United States, approaches are needed to prevent this problem at the community level. In the Mount Rogers *Health* District (MRHD) (1990 population: 178,000), a six-county area in southwestern Virginia, age-adjusted death rates for CVD substantially exceed state and national averages. In August 1987, the MRHD implemented the *Worksite* and Community *Health* *Promotion/Risk* Reduction Project to help residents of this large, rural area improve their *health* by adopting healthy lifestyles and, consequently, reduce their risks for CVD and cancer. This report summarizes activities
