Acknowledgments:

I would first like to thank my thesis advisor, Maureen Mork, for her endless support throughout this project. Her guidance and expertise was invaluable to every stage of this research.

I would also like to thank each of my committee members for their assistance and contributions to this research. Their willingness to help and provide their perspective is much appreciated.

Additionally, I am grateful for all the genetic counselors who took the time to complete our survey. This research would have been impossible without their enthusiasm to support this project.
GENETIC COUNSELOR UTILIZATION AND INTERPRETATION OF SOMATIC TUMOR TESTING IN EVALUATION FOR LYNCH SYNDROME

Danielle Rae Williams, B.A.
Advisory Professor: Maureen Mork, M.S.

Lynch syndrome (LS) is a hereditary cancer predisposition syndrome characterized by increased risk for colorectal and uterine cancers. Individuals with pathogenic variants in the mismatch repair (MMR) genes (MLH1, MSH2/EPCAM, MSH6, PMS2) are diagnosed with LS and subsequently recommended to proceed with high risk screening protocols to increase prevention and early detection of LS-related cancers. Various tumor studies can help identify those at high risk for LS, but sometimes create uncertainty with discordant screening and germline results, leading to unexplained mismatch repair deficiency (UMMRD). Somatic testing of the MMR genes has created opportunities for resolving UMMRD, thus clarifying LS status and ensuring appropriate cancer surveillance. However, guidelines for such testing are currently limited. The purpose of this study was to examine current and hypothetical ordering practices of cancer genetic counselors for LS evaluation and to investigate participants’ interpretation of somatic MMR testing results. Two-hundred eligible participants were recruited through the National Society of Genetic Counselors listserv and answered questions regarding demographics, ordering practices, barriers to somatic MMR testing, theoretical patient scenarios, and need for further guidelines. Statistical analysis was done using Chi-square, Fisher exact, and Wilcoxon rank-sum tests while themes were identified from free-text responses. Most respondents did not include somatic MMR testing in the work-up for LS and did not routinely order this testing, but indicated interest in ordering this in conjunction with germline testing. The gap between preferred testing strategies and current ordering practices for somatic MMR testing may be due to reported laboratory and insurance-related barriers, particularly cost and coordination of tissue specimens. Nearly all individuals endorsed the need for additional guidelines for somatic MMR
testing, which could provide support to reduce barriers, encourage insurance coverage, and allow for appropriate screening recommendations for patients and family members of those with UMMRD.

INTRODUCTION

Lynch syndrome (LS), formerly known as hereditary nonpolyposis colorectal cancer (HNPCC), is one of the most prevalent and well-defined hereditary cancer syndromes (Lynch et al., 2015). It is caused by germline heterozygous pathogenic variants in the mismatch repair (MMR) genes (*MSH2*, *MSH6*, *MLH1*, and *PMS2*), as well as *EPCAM*. (Lynch et al., 2015; Tiwari et al., 2016; Pena-Diaz et al., 2015). Individuals with LS have an increased lifetime risk for colorectal and uterine cancers as well as extracolonic cancers of the ovary, renal pelvis, stomach, small bowel, brain, and sebaceous gland compared to the general population (Lynch et al., 2015; Tiwari et al., 2016; Vasen et al., 1999).

Individuals with LS tend to have an earlier age of diagnosis and a higher rate of multiple primary cancers than the general population (Lynch et al., 2015; Tiwari et al., 2016; Vasen et al., 1999).

Microsatellite instability (MSI) analysis and immunohistochemistry (IHC) staining are often initial tumor screens used to identify individuals at increased risk for LS (Battaglin et al., 2018; Cohen et al., 2014; Tiwari et al., 2016). MSI analysis determines the mutation status of microsatellite repeats and those with more mutated sequences are deemed MSI-high, which can be an indication of MMR deficiency (Lynch et al., 2015; Pena-Diaz et al., 2015; Tiwari et al., 2016). IHC staining can be used to determine MMR protein status in the tumor; absence of staining in one or more of these proteins raises suspicion for a germline pathogenic variant in one of the MMR genes (Lynch et al., 2015; Pritchard, et al., 2012). *MLH1* promoter hypermethylation and/or *BRAF* somatic mutation analyses also contribute to risk assessment as the presence of either *MLH1* promoter hypermethylation or the V600E mutation in *BRAF* are associated with sporadic MSI-high tumors as opposed to LS (Deng et al., 2004; McGivern et al., 2004).

In addition to *MLH1* promoter hypermethylation and *BRAF* V600E mutations, biallelic (or “double”) somatic MMR mutations can also be responsible for some MMR deficient cancers in the absence of a germline mutation, also known as unexplained mismatch repair deficiency (UMMRD) (Mesenkamp et al., 2014; Sourrouille et al., 2012). UMMRD can be due to undetectable germline pathogenic variants and large rearrangements, somatic mosaicism, false-positive staining, or biallelic
somatic mutations (Haraldsdottir et al., 2014). Individuals with biallelic somatic mutations are considered unlikely to have LS because these cases are either caused by two somatic mutations or one somatic mutation combined with somatic loss of heterozygosity, thus resulting in MMR deficiency in the tumor (Buecher et al., 2018; Mesenkamp et al., 2014). Biallelic somatic MMR mutations may explain up to 52% of UMMRD, helping to inform LS status and potentially sparing patients and their families from intensive cancer screenings (Mensenkamp et al., 2014; Sourrouille et al., 2012).

Biallelic somatic MMR mutations cannot be differentiated from LS using tumor pathology, MSI analysis, or IHC staining, so challenges arise when UMMRD occurs (Haraldsdottir et al., 2014; Hemminger et al., 2018). However, next-generation sequencing has led to more frequent utilization of tumor profiling to pinpoint somatic mutations (Hamepl et al., 2018; Pritchard et al., 2012; Varga et al., 2015) and can be applied to LS tumors as an additional risk assessment tool.

Even though there are opportunities to utilize somatic testing in the evaluation of LS, the corresponding guidelines have not caught up to the available technology. There is currently no consensus about the LS status of individuals with UMMRD (Batte, et al, 2013) and, somatic MMR testing does not explain all MSI-high tumors without a germline mutation. This creates dilemmas for genetic counselors and physicians in providing screening recommendations. Only 5.2% of genetic counselors have reported being “completely prepared” and 67% reported being “somewhat prepared” to handle comprehensive tumor profiling results (Goedde et al., 2017). However, it is still unknown how this applies to LS somatic MMR testing. The National Comprehensive Cancer Network (NCCN) current guidelines (NCCN, Version 1.2018) contain limited recommendations for the interpretation of somatic MMR testing for LS in a footnote (LS-A 4 of 5; footnote d). The footnote discusses biallelic somatic MMR mutations as a possible explanation for UMMRD and suggests genetic consultation for complex results without guidelines for interpreting complex results. This minimal guidance leaves room for inconsistency among genetic counseling practices.

The availability of somatic MMR testing in evaluation of LS has great implications for patient management, but its use among cancer genetic counselors has not been studied. Thus, we aimed to
investigate current somatic MMR ordering practices, and consistency in risk assessments by cancer genetic counselors to identify gaps in available recommendations and assess the need for more comprehensive guidelines.

METHODS

This study was approved by the University of Texas Health Science Center Institutional Review Board, governed by the Committee for the Protection of Human Subjects (HSC-MS-18-0442).

Participants and Procedures:

Participants were recruited to this cross-sectional study through the National Society of Genetic Counselors (NSGC) listserv between September 2018 and November 2018. A survey link was sent via email to all NSGC registered members, followed by a reminder, and posted to the Cancer Special Interest Group (SIG) discussion board. Practicing board-certified or board-eligible clinical genetic counselors, who actively see patients in the cancer setting, were eligible to participate in the study. The survey was anonymous and remained open for 8 weeks. Informed consent was obtained prior to proceeding to the questionnaire portion of the survey. Participants were excluded from the study if they were employed by a diagnostic laboratory, did not meet the eligibility criteria, or only completed the demographic section of the survey.

Instrumentation:

Qualtrics (Qualtrics, Provo, UT) was used to administer the survey and collect data. Participants who consented to the study were asked eligibility criteria, demographic information, current ordering practices, scenarios involving hypothetical patients, and views on further guidelines. The subjects were given an opportunity for free-text comments at the end of the survey. The question format varied, with the vast majority (45/53 content questions) being multiple choice. Subjects could exit the survey at any
point, and subjects were not required to answer every question. The study questionnaire was created by the authors and was not externally validated (Appendix A).

**Data Analysis:**

Data was analyzed using STATA (version 13.1, College Station, TX) with a level of significance of \( p \leq 0.05 \). Descriptive statistics were completed including medians for continuous variables and frequencies and percentages for categorical variables. Demographic responses were compared to the results of the NSGC 2018 Professional Status Survey (PSS) using proportion tests. Chi-square, Fisher exact, and Wilcoxon rank-sum tests were used to compare differences between responses for selected questions and estimate the significance. Free responses were analyzed to identify themes within participant comments, with the flexibility to code multiple themes for one response.

**RESULTS**

**Demographics:**

Following the survey closure, there were 224 total responses. Thirteen responses were excluded due to ineligibility, while 11 did not meet the minimum completeness requirement and were also excluded. The remaining 200 respondents were included in the study. Since participants were not required to answer every question, the total number of responses varied across questions. Demographic information is reported in Table 1. The majority of participants worked full-time (98%, \( n = 195/200 \)), had less than six years of experience in a cancer setting (75%, \( n = 150/200 \)), and did not practice additional specialties (69%, \( n = 137/200 \)). Most individuals (86%, \( n = 171/200 \)) worked with other genetic counselors. Just over half (52%, \( n = 103/198 \)) of respondents practiced in a state with licensure. The median number of colorectal cancer cases assessed per month (personal or family history) was five (Interquartile range: 4-10) and the median number of uterine cancer cases assessed per month (personal or family history) was three (Interquartile range: 2-5). Demographics were compared to the 2018 NSGC PSS and did not reveal any statistically significant differences for licensure status or regions 1-5. Region
6 was underrepresented in our responses compared to the PSS. While different work setting options were presented in the two surveys, there were no statistically significant differences for the proportion of individuals at a university medical center or in a private medical facility. However, there were a higher proportion of genetic counselors who worked at a public medical facility in our cohort compared to the PSS.

### Ordering Practices:

Participants were asked about their institution’s ordering practices for IHC, MSI, and somatic MMR testing in the work-up for LS. These responses are reported in Table 2. Most individuals (91%, n = 181/200) reported their institution included IHC and the majority of those (85%, n = 154/181) used an in-house laboratory. Less than half (44%, n = 87/199) worked at an institution that included MSI in the LS work-up, with the majority (74%, n = 64/87) performed at an in-house laboratory. Genetic counselors who worked in an academic setting were more likely to have an institution that used an in-house laboratory for both IHC (p = 0.003) and MSI (p < 0.0001) testing than those not at an academic institution. Less than a third (29%, n = 57/199) of respondents reported their institution included somatic MMR testing in evaluation of LS, with the majority (66%, n = 37/56) performed at an external laboratory. Of those who had experience ordering somatic MMR testing, less than a quarter (23%, n = 28/124) reported “routinely” ordering this testing and half (50%, n = 62/124) reported only using this testing “occasionally” or “rarely”.

The survey also investigated genetic counselor experience and comfort level with both tumor profiling and somatic MMR testing. Most individuals (83%, n = 165/198) had experience with tumor profiling results (such as those obtained from external vendors such as FoundationOne) and the majority (62%, n = 122/197) reported they felt “somewhat comfortable” or “extremely comfortable” interpreting these types of results. The majority of respondents (81%, n = 161/198) had experience reviewing somatic MMR testing results, with nearly three-quarters (73%, n = 117/159) of those results “usually contributing” or “always contributing” to the risk assessment of LS cases. When participants were asked if they do or would feel comfortable interpreting somatic MMR results, 85% (n = 166/195) reported they felt “somewhat comfortable” or “extremely comfortable”.

Over three-quarters (76.8%, n = 149/194) of respondents experienced or perceived barriers to ordering somatic MMR testing, with cost and coordinating tissue samples being the most frequently cited. The reported barriers are summarized in Figure 1. Genetic counselors at an academic institution were more likely (p = 0.024) to cite lack of in-house availability as a barrier to somatic MMR testing compared to those not at an academic institution. Those who work with other cancer genetic counselors were more likely to experience or perceive barriers to somatic MMR testing than those who were the sole cancer genetic counselor at their institution (p = 0.029).

Scenario-based Questions:

During the scenario portion of the survey, participants were given four different theoretical scenarios created by the authors with information about a hypothetical patient’s diagnosis and tumor staining results in addition to a pedigree. Question topics included the likelihood of the patient having LS (before and after learning the patient’s somatic MMR results), the next recommended step in the genetics evaluation, and screening recommendations for the patient and first-degree relatives. The pedigrees for these scenarios are displayed in Figure 2.

Scenario 1 (Figure 2: A) involved a 67-year old male with colorectal cancer that had loss of staining in MLH1 and PMS2 with negative *MLH1* promoter methylation and *BRAF* mutation analysis. This patient was later revealed to have biallelic somatic mutations in *MLH1* with negative germline testing. Scenario 2 (Figure 2: B) was a 23-year old female with colorectal cancer and a noncontributory family history. Tumor testing showed loss of staining in MSH2 and MSH6. Somatic testing showed biallelic somatic mutations in *MSH2* and germline testing was negative. Scenario 3 (Figure 2: C) showed a 46-year old female with uterine cancer and family history meeting Amsterdam criteria. The tumor IHC results were loss of staining in MSH2 and MSH6. Participants were later informed her somatic testing
showed a monoallelic mutation in *MSH2* with negative germline testing. Scenario 4 (Figure 2: D) involved a 62-year old male with colorectal cancer and loss of staining in MLH1 and PMS2 with negative *MLH1* promoter methylation and *BRAF* mutation analysis. His family history was noncontributory, although his unaffected father died at age 52. Both the somatic and germline testing results were negative.
Figure 2. Scenario pedigrees (A-D) provided to participants.
For all scenarios, the majority (52-59%) of participants indicated their next step would have been concurrent germline and somatic testing that included the MMR genes. For the scenarios involving biallelic somatic mutations, the initial likelihood for LS was mostly ranked as “unlikely” (scenario 1; 79%, n = 152/192) or “highly likely” (scenario 2; 82%, n = 155/190). After learning the somatic testing results for these scenarios, the majority (77%, n = 148/192; 89%, n = 169/190 for scenario 1 and 2, respectively) of respondents shifted to a lower LS likelihood of either “unlikely” or “definitely not”. For the scenario regarding monoallelic somatic mutations (scenario 3), most participants indicated “highly likely” before (88%, n = 165/187) and after (75%, n = 139/186) knowing the patient’s somatic results, with most (71%, n = 133/186) individuals selecting the same likelihood for both questions. Scenario 4 involved a patient with negative somatic and germline results, with most (59%, n = 105/177) individuals ranking the likelihood for LS as “unlikely” for both risk assessment questions and approximately a quarter (28%, n = 50/177) downgrading their LS suspicion. Most individuals recommended LS screening for the patient (81%, n = 149/185) with monoallelic somatic mutations (scenario 3) and her first-degree relatives (68%, n = 128/187). For the other three scenarios, the majority screening recommendation was “population-level” for the proband (48-66%) and “early colonoscopy based on family history” for the first-degree relatives (56-90%). The scenario responses are summarized in Table 3.

**Key**
- * Somatic test results provided after Q2
- ** Negative MLH1 methylation and BRAF mutation analysis

### Further Guidelines and Comments:

When asked if additional, more specific, national guidelines for the ordering and/or interpretation of MMR somatic testing would be beneficial, 77% (n=140) of respondents answered ‘yes’ and 17% (n=31) responded ‘maybe’.

At the conclusion of the survey, participants were given an opportunity to provide additional comments in a free-text format. Select comments are displayed in Table 4. While extensive patterns in
the comment section did not emerge, a few individuals confirmed further guidelines would be helpful. A few others also reiterated that in their experiences, concurrent germline and somatic testing was beneficial for billing purposes. None of the comments provided explanations for individuals who indicated they did not feel further guidelines would be helpful.

</table>
| **Barriers to Somatic Testing** | “While we may want to start with germline and then reflex to somatic (in some cases)... there is better coverage to order concurrently; so while it may not clinically be the best way to order testing, it is financially better for our patients.”  
“Turnaround time is also a contributing factor... I would sacrifice somatic results for germline results in those cases where surgical decision making regarding Lynch syndrome are reliant upon results...” |
| **Further Guidelines**       | “Our clinic is getting more and more questions from oncologists at our institution regarding tumor testing for Lynch and other conditions. National guidelines for tumor testing in general would be extremely beneficial for cancer genetic counseling.”  
“Additional information on interpretation of MMR somatic tumor testing would be extremely beneficial. A lot has been learning as I go and I am not sure I am doing that great of a job at it...” |
| **Screening Recommendations** | “We make guideline recommendations based on the NCCN guidelines. In some situations, we may encourage more high risk screening methods... but we defer to the patient’s supervising physician...”  
“For those with abnormal results and no informative germline/somatic results there is no clear cut recommendations and every family needs to be looked at individual and notes should include limitations to our knowledge and any recommendations.” |
DISCUSSION

Cancer genetic counselors currently have several tools available to assess an individual’s risk of LS, including IHC staining, MSI analysis, somatic MMR testing, and germline testing. While not all of these tools may be indicated in every case, UMMRD cases may require more extensive testing to accurately determine LS status and ultimately screening recommendations for patients and their relatives. Given the importance of appropriate patient management, this study surveyed two hundred currently-practicing cancer genetic counselors regarding their current ordering practices and interpretation of somatic MMR results in the context of a hypothetical LS case to evaluate the sufficiency of current national guidelines. The results of this survey demonstrate cancer genetic counselors’ acknowledged importance of somatic MMR testing in theoretical practice and in past instances, despite a scarcity of routine inclusion in real-world ordering practices.

Cancer genetic counselors seem to be largely aware of the benefits of somatic MMR testing and demonstrate interest in ordering it for their patients. Participants with past experience utilizing somatic MMR testing indicated the positive impact these results had on risk assessment. This sentiment was also reflected in the hypothetical scenarios, as a majority of participants indicated they would consider somatic MMR testing in conjunction with germline testing as the ideal next step in their LS evaluation. Previous literature has shown that patients also tend to positively view tumor screening for LS and understand its benefits (Hunter et al., 2015).

Despite genetic counselor understanding of its benefits, somatic MMR testing was rarely included in the respondents’ current institution ordering practices for LS work-up. While most respondents had previous experience ordering somatic MMR testing and reported feeling at least “somewhat comfortable” with interpreting these results, only a small minority reported routinely ordering this testing. The discrepancy between ideal and current testing practices illustrates a gap, perhaps related to barriers to testing.

In fact, a high frequency of genetic counselors reported encountering or perceiving barriers to ordering somatic MMR testing. The most common reported barriers included cost, coordinating tissue
samples, and lack of in-house availability, with lack of knowledge regarding result interpretation among the least frequently cited. Many individuals reported additional barriers in the free-text response, with themes emerging in billing/insurance issues, long turnaround time, and lack of tumor tissue. Since these themes were individually reported as free-text responses and not displayed as options to all participants, these barriers may be underrepresented in this study. Previous literature regarding ordering tumor profiling found each of these three barriers to be reported in more than 70\% of their participants (Kurzrock et al., 2015), which may be similar in somatic MMR testing.

Interestingly, genetic counselors who were the sole genetic counselor at their institution were less likely to report experiencing these barriers. This may be an indication that sole genetic counselors are viewed to have slightly different scopes of practice or perhaps reflects a difference in clinic structure or institution size.

The vast majority of participants reported that additional, more specific, national guidelines surrounding somatic MMR testing would be beneficial to their practice. The NCCN current guidelines (NCCN, Version 1.2018) includes limited recommendations for the interpretation of somatic MMR testing in the form of a footnote (LS-A 4 of 5; footnote d). This footnote cites evidence supporting biallelic somatic MMR mutations as an explanation for UMMRD, therefore tumor sequencing may assist in clarifying the result. It discusses that in cases with monoallelic somatic mutations, the unidentified mutation could be germline or somatic. However, the guidelines state family history-based management should be used regardless of somatic testing results. The footnote also suggests genetic consultation for complex results but doesn’t provide guidelines for interpreting those results. While there are mentions of somatic MMR testing in national guidelines, it does not encompass all possible scenarios, and is not nearly as extensive as guidelines for germline testing. The creation of clear guidelines may further increase genetic counselor comfort with ordering somatic MMR testing and encourage them to seek out this testing more often, thereby enhancing patient management. Since some insurance companies use national guidelines to determine coverage criteria, this may also reduce insurance and billing issues.
Study limitations:

This study population may reflect a self-selecting bias in which those genetic counselors with experience or interest in somatic MMR testing may have been more likely to complete the survey than those with more limited knowledge. In addition, the questionnaire was created by the authors and has not been formally validated. While most participant characteristics were not significantly different between this study and the PSS, including licensure and regions 1-5, this study may have had a higher proportion of genetic counselors who worked at a public medical facility and a lower proportion of genetic counselors in region 6, which could have created a skewed sample. However, the work setting differences may simply be a reflection of different answer choices included on this survey compared to those of the PSS. Additionally, the NCCN guidelines underwent revisions within a few months of survey distribution which changed recommendations for those with monoallelic somatic mutations from LS screening to family history-based screening. Therefore, individuals may have made recommendations for LS screening as a reflection of prior guidelines.

Of note, for three of the scenario questions, it was observed that a majority of participants chose “population-level screening” for a proband affected with cancer. However, individuals with a history of cancer generally require additional screening compared to the general population in order to monitor for disease recurrence. Therefore, this survey response may represent an artifact of the survey structure or wording for this specific question. While the authors intended this to represent typical post-cancer screening protocols, this phrase may have been interpreted differently by respondents. Given the only other provided response was LS screening, this option may have been understood as non-LS screening or as typical screening for the colon/uterine cancer population. Therefore, conclusions could not be drawn regarding these responses.

Practice Implications:

This study provides insights into the ordering practices of cancer genetic counselors in evaluating for LS, interpretations of somatic MMR testing, and barriers to this testing. Since many of the
reported barriers involved lab-related issues rather than knowledge, it may be beneficial for genetic counselors to advocate for different lab billing practices or in-house somatic MMR testing to ensure this option is available, especially for UMMRD cases.

While many genetic counselors reported some level of comfort with interpreting somatic MMR testing results, further guidelines may allow for further consensus, higher comfort levels, and portray benefit to insurance companies. This may provide genetic counselors with more guideline resources, confidence in their abilities to interpret somatic MMR testing, and leverage when advocating for this testing option. Further guidelines may also reflect larger consensus and wider acceptance as a risk assessment tool, which may aid in lowering costs and improving insurance coverage.

**Research Recommendations:**

Further studies investigating the barriers to somatic MMR testing may be beneficial in determining strategies for eliminating or reducing those barriers. These potential studies could also explore and confirm the differences between sole genetic counselors and those who work along with other genetic counselors in terms of ordering practices, comfort with somatic testing, and likelihood to report barriers to somatic MMR testing. Advancements in genetic knowledge and cancer technologies may create other avenues for LS risk assessment or reveal other explanations for UMMRD, which may alter ordering practices. Future research could compare ordering practices over time to find other factors contributing to the rate of testing uptake and accessibility of new testing options.
APPENDIX

Appendix A. Complete survey of this study

Start of Block: Consent

Q1 You are invited to take part in a research study called, “Genetic Counselor Utilization and Interpretation of Somatic Tumor Testing for Lynch Syndrome”, conducted by Danielle Williams, of The University of Texas MD Anderson Cancer Center UTHealth Graduate School of Biomedical Sciences.

The purpose of this study is to describe current clinical practice among genetic counselors seeing cancer patients for evaluation of Lynch syndrome. All board-certified or board-eligible genetic counselors who see cancer patients are invited to participate, regardless of exposure to somatic tumor testing.

If you consent to take part in this study you will complete a 15-20 minute survey via the online survey tool, Qualtrics. All survey submissions will be anonymous.

The information you provide will help us better understand current clinical practices of cancer genetic counselors evaluating patients for Lynch syndrome. You may not receive any direct benefit from taking part in this study. The only possible risk may be breach of confidentiality; the information collected will not contain identifying information. You have the alternative to choose to not take part in this study and may withdraw at any time.

There is no cost and you will not be paid to take part in this study. You will not be personally identified in any reports or publications that may result from this study. Any personal information about you that is gathered during this study will remain confidential to every extent of the law.

This research project has been reviewed by the Committee for the Protection of Human Subjects (CPHS) of the University of Texas Health Science Center at Houston (HSC-MS-18-0442). For any questions about research subjects rights call CPHS at (713) 500-7943. This study is being conducted by M.S. Candidate Danielle Williams under the direction of Maureen Mork, M.S., C.G.C. Should you have any questions, please feel free to contact either at danielle.williams@uth.tmc.edu or memork@mdanderson.org.

- I have read the consent and agree to take part in the study (1)
- I do not provide my consent and/or do not wish to take part in the study (2)

Skip To: End of Survey If You are invited to take part in a research study called, “Genetic Counselor Utilization and Interpretation of Somatic Tumor Testing for Lynch Syndrome” = I do not provide my consent and/or do not wish to take part in the study

Start of Block: Qualification Questions

Q2 Are you a currently practicing, board certified or board eligible, genetic counselor who sees patients for evaluation of hereditary cancer?

- Yes (1)
- No (2)

Skip To: End of Survey If Are you a currently practicing, board certified or board eligible, genetic counselor who sees pat... = No

Q3 Do you work in a clinical or non-clinical setting?

- I am a clinical counselor and counsel patients as a regular part of my job (1)
- I am a non-clinical counselor and typically do not counsel patients (2)

Skip To: End of Survey If Do you work in a clinical or non-clinical setting? = I am a non-clinical counselor and typically do not counsel patients

Start of Block: Demographics
Q4 For how many years have you been seeing patients for evaluation of hereditary cancer?
   o 0-5 years (1)
   o 6-10 years (2)
   o 11-15 years (3)
   o 16-20 years (4)
   o 20+ years (5)

Q5 Do you work as a genetic counselor full-time or part-time?
   o Part-time (1)
   o Full-time (>30 hours per week) (2)

Q6 What type of setting do you work in? Select all that apply
   □ Public hospital/medical facility (1)
   □ Private hospital/medical facility (2)
   □ University Medical Center (3)
   □ Physician’s private practice (4)
   □ Diagnostic laboratory (5)
   □ Other (6) ________________________________________________

Q7 Does your employer offer somatic MMR testing? (Haraldsdottir et al., 2014; Mensenkamp et al., 2014; NCCN, Version 3.2017)
   o Yes (1)
   o No (2)

Skip To: End of Survey If Does your employer offer somatic MMR testing?... = No

Q8 Do you consider your workplace to be an academic or non-academic institution?
   o Academic (1)
   o Non-academic (2)

Q9 Do you exclusively see cancer cases?
   o Yes (1)
   o No, I see other specialties as well (2)

Display This Question: If Do you exclusively see cancer cases? = No, I see other specialties as well

Q10 What other specialties do you see? Select all that apply
   □ General genetics (1)
   □ Pediatrics (2)
   □ Adult genetics (3)
   □ Cardiology (4)
   □ Neurogenetics (5)
   □ Metabolic diseases (6)
   □ Prenatal (7)
   □ Other (8) ________________________________________________

Q11 Do you specialize in a certain domain within the cancer setting?
   o Yes (1)
No, I practice in a general cancer genetics setting (2)

Display This Question: If Do you specialize in a certain domain within the cancer setting? = Yes

Q12 Which cancer domain do you specialize in? Select all that apply

- Breast (1)
- Gynecological (2)
- Gastrointestinal (GI) (3)
- Genitourinary (GU) (4)
- Endocrine (5)
- Dermatology (6)
- Pediatric (7)
- Other (8) _________________________________________

Q13 Do you work with other cancer genetic counselors?

- Yes, I work with other cancer genetic counselors (1)
- No, I am the only cancer genetic counselor at my institution (2)

Q14 In which region do you currently practice?

- Region 1 (CT, MA, ME, NH, RI, VT, CN Maritime Provinces) (1)
- Region 2 (DC, DE, MD, NJ, NY, PA, VA, WV, PR, VI, Quebec) (2)
- Region 3 (AL, FL, GA, KY, LA, MS, NC, SC, TN) (3)
- Region 4 (AR, IA, IL, IN, KS, MI, MN, MO, ND, NE, OH, OK, SD, WI, Ontario) (4)
- Region 5 (AZ, CO, MT, NM, TX, UT, WY, Alberta, Manitoba, Sask) (5)
- Region 6 (AK, CA, HI, ID, NV, OR, WA, British Columbia) (6)

Q15 Does your state/province currently have licensure?

- Yes (1)
- No (2)

Start of Block: Current practices

Q16 About how many cases (personal or family history) do you see per month for colorectal cancer?

Q17 About how many cases (personal or family history) do you see per month for uterine cancer?

Q18 Does your institution include immunohistochemistry (IHC) tumor staining in the work-up for Lynch syndrome?

- Yes (1)
- No (2)
- Unsure (3)

Display This Question: If Does your institution include immunohistochemistry (IHC) tumor staining in the work-up for Lynch... = Yes

Q19 Is IHC testing performed in-house or through a send-out laboratory?

- In-house (1)
- Send-out (2)
- Unsure (3)

Q20 Does your institution include microsatellite instability (MSI) testing in the work-up for Lynch syndrome?
Q21 Is MSI testing performed in-house or through a send-out laboratory?
- In-house (1)
- Send-out (2)
- Unsure (3)

Q22 Does your institution include somatic tumor testing of the mismatch repair (MMR) genes in the work-up for Lynch syndrome? (Haraldsdottir et al., 2014; Mensenkamp et al., 2014; NCCN, Version 3.2017)
- Yes (1)
- No (2)
- Unsure (3)

Q23 Is MMR somatic tumor testing performed in-house or through a send-out laboratory?
- In-house (1)
- Send-out (2)
- Unsure (3)

Q24 Do you have experience with tumor profiling testing results (FoundationOne)?
- Yes (1)
- No (2)

Q25 How comfortable do you feel interpreting tumor profiling results (FoundationOne)?
- Extremely comfortable (1)
- Somewhat comfortable (2)
- Neither comfortable nor uncomfortable (3)
- Somewhat uncomfortable (4)
- Extremely uncomfortable (5)

Q26 Have you ever ordered and/or coordinated somatic tumor testing of the MMR genes in evaluation of Lynch syndrome?
- Yes (1)
- No (2)

Q27 Have you ever ordered and/or coordinated somatic testing of the MMR in evaluation of Lynch syndrome for a colon tumor?
- Yes (1)
- No (2)

Q28 Have you ever ordered and/or coordinated somatic testing of the MMR genes in evaluation of Lynch syndrome for a uterine tumor?
- Yes (1)
Display This Question: If Have you ever ordered and/or coordinated somatic tumor testing of the MMR genes in evaluation of... = Yes

Q29 Is somatic MMR testing utilized when are evaluating a patient for Lynch syndrome?
  o Rarely (1)
  o Occasionally (10-30% of the time) (2)
  o Often (30-80% of the time) (3)
  o Routinely (>80% of the time) (4)

Q30 Have you ever reviewed/interpreted colon or uterine MMR somatic tumor testing results?
  o Yes (1)
  o No (2)

Display This Question: If Have you ever reviewed/interpreted colon or uterine MMR somatic tumor testing results? = Yes

Q31 In the cases where you have reviewed/interpreted somatic MMR tumor testing results, did those results contribute to your Lynch syndrome risk assessment?
  o Always (100% of the time) (1)
  o Usually (70-99% of the time) (2)
  o Sometimes (30-70% of the time) (3)
  o Rarely (1-30% of the time) (4)
  o Never (0% of the time) (5)

Display This Question: If Have you ever reviewed/interpreted colon or uterine MMR somatic tumor testing results? = No

Q32 What are the reasons that contribute to not reviewing/interpreting colon or uterine MMR somatic tumor testing results? Select all that apply
  □ I don’t feel comfortable interpreting somatic tumor testing results (1)
  □ I have not received training for interpreting somatic tumor testing results (2)
  □ The results wouldn’t contribute to my risk assessment (3)
  □ My institution doesn’t order somatic testing (4)
  □ We have other providers to do this (5)
  □ I don’t have time to review the results (6)
  □ My institution does not consider this part of the genetic counseling scope (7)
  □ Other (8) ____________________________________________

Q33 Have you experienced or perceive any barriers to ordering somatic MMR testing?
  o Yes (1)
  o No (2)

Q34 What are the barriers you have experienced or perceive? Select all that apply
  □ Cost (1)
  □ Coordinating tissue samples (2)
  □ Lack of institution support (3)
  □ Unsure how to interpret the results (4)
☐ Lack of time (5)
☐ Not available in-house (6)
☐ Not offered by preferred genetic testing lab(s) (7)
☐ Other (8) ________________________________________________

Q35 Do/would you feel comfortable interpreting colon and/or uterine MMR somatic tumor testing results and including them in your risk assessment?
  o Extremely comfortable (1)
  o Somewhat comfortable (2)
  o Neither comfortable nor uncomfortable (3)
  o Somewhat uncomfortable (4)
  o Extremely uncomfortable (5)

Start of Block: Scenario 1

Q36 The following questions refer to the scenario below:
Mr. Smith is a 67-year old male recently diagnosed with colorectal cancer. Tumor testing revealed loss of staining in *MLH1* and *PMS2*. *MLH1* promoter methylation and *BRAF* mutation analysis were both negative. The patient's family history is below:

![Family Tree Diagram]

Q38 What would you perceive this patient’s chance of having Lynch syndrome to be?
  o This patient absolutely has Lynch syndrome (1)
  o It’s highly likely this patient has Lynch syndrome (2)
  o It’s unlikely this patient has Lynch syndrome (3)
  o This patient definitely does not have Lynch syndrome (4)

Q39 What would be your next step in evaluating this patient for Lynch syndrome?
  o Germline testing to include MMR genes (1)
  o Germline testing to include MMR genes with reflex to somatic MMR testing if negative (2)
  o Concurrent germline testing to include MMR genes plus somatic MMR testing (3)
  o No further evaluation (4)
  o Other (5) ________________________________________________
Q40 Somatic MMR testing reveals biallelic somatic mutations in *MLH1*. Germline testing for MMR genes was negative. Given this additional information, what do you perceive this patient’s chance of having Lynch syndrome to be?
- This patient absolutely has Lynch syndrome (1)
- It’s highly likely this patient has Lynch syndrome (2)
- It’s unlikely this patient has Lynch syndrome (3)
- This patient definitely does not have Lynch syndrome (4)

Q41 What screening recommendations would you give this patient?
- Population-level screening (1)
- Lynch syndrome screening (2)
- Other (3) ________________________________

Q42 What screening recommendations would you give this patient’s first-degree relatives?
- Population-level screening (1)
- Earlier colonoscopy based on family history (2)
- Lynch syndrome screening (3)
- Other (4) ________________________________

Start of Block: Scenario 2

Q43 The following questions refer to the scenario below:
Ms. Jones is a 23-year old female recently diagnosed with colorectal cancer. Tumor testing revealed loss of staining in *MSH2* and *MSH6*. The patient’s family history is below:

Q44 What would you perceive this patient’s chance of having Lynch syndrome to be?
- This patient absolutely has Lynch syndrome (1)
- It’s highly likely this patient has Lynch syndrome (2)
- It’s unlikely this patient has Lynch syndrome (3)
- This patient definitely does not have Lynch syndrome (4)

Q45 What would be your next step in evaluating this patient for Lynch syndrome?
- Germline testing to include MMR genes (1)
- Germline testing to include MMR genes with reflex to somatic MMR testing if negative (2)
- Concurrent germline testing to include MMR genes plus somatic MMR testing (3)
- No further evaluation (4)
- Other (5) ________________________________
Q46 Somatic MMR testing reveals biallelic somatic mutations in \textit{MSH2}. Germline testing for MMR genes was negative. Given this additional information, what do you perceive this patient’s chance of having Lynch syndrome to be?

- This patient absolutely has Lynch syndrome (1)
- It’s highly likely this patient has Lynch syndrome (2)
- It’s unlikely this patient has Lynch syndrome (3)
- This patient definitely does not have Lynch syndrome (4)

Q47 What screening recommendations would you give this patient?

- Population-level screening (1)
- Lynch syndrome screening (2)
- Other (3)

Q48 What screening recommendations would you give this patient’s first-degree relatives?

- Population-level screening (1)
- Earlier colonoscopy based on family history (2)
- Lynch syndrome screening (3)
- Other (4)

Start of Block: Scenario 3

Q49 The following questions refer to the scenario below:

Ms. Davis is a 46-year old female recently diagnosed with uterine cancer. Tumor testing revealed loss of staining in \textit{MSH2} and \textit{MSH6}. The patient’s family history is below:

![Family tree diagram]

Q50 What would you perceive this patient’s chance of having Lynch syndrome to be?

- This patient absolutely has Lynch syndrome (1)
- It’s highly likely this patient has Lynch syndrome (2)
- It’s unlikely this patient has Lynch syndrome (3)
- This patient definitely does not have Lynch syndrome (4)

Q51 What would be your next step in evaluating this patient for Lynch syndrome?

- Germline testing to include MMR genes (1)
- Germline testing to include MMR genes with reflex to somatic MMR testing if negative (2)
- Concurrent germline testing to include MMR genes plus somatic MMR testing (3)
- No further evaluation (4)
Q52 Somatic MMR testing reveals a monoallelic somatic mutation in *MSH2*. Germline testing for MMR genes was negative. Given this additional information, what do you perceive this patient’s chance of having Lynch syndrome to be?
- This patient absolutely has Lynch syndrome (1)
- It’s highly likely this patient has Lynch syndrome (2)
- It’s unlikely this patient has Lynch syndrome (3)
- This patient definitely does not have Lynch syndrome (4)

Q53 What screening recommendations would you give this patient?
- Population-level screening (1)
- Lynch syndrome screening (2)
- Other (3) ________________________________________________

Q54 What screening recommendations would you give this patient’s first-degree relatives?
- Population-level screening (1)
- Earlier colonoscopy based on family history (2)
- Lynch syndrome screening (3)
- Other (4) ________________________________________________

Start of Block: Scenario 4

Q55 The following questions refer to the scenario below:
Mr. Roberts is a 62-year old male recently diagnosed with colorectal cancer. Tumor testing revealed a loss of staining in *MLH1* and *PMS2*. *MLH1* promoter methylation and *BRAF* mutation analysis were both negative. The patient’s family history is below:

![Scenario 4](image)

Q56 What would you perceive this patient’s chance of having Lynch syndrome to be?
- This patient absolutely has Lynch syndrome (1)
- It’s highly likely this patient has Lynch syndrome (2)
- It’s unlikely this patient has Lynch syndrome (3)
- This patient definitely does not have Lynch syndrome (4)

Q57 What would be your next step in evaluating this patient for Lynch syndrome?
- Germline testing to include MMR genes (1)
Germline testing to include MMR genes with reflex to somatic MMR testing if negative (2)
Concurrent germline testing to include MMR genes plus somatic MMR testing (3)
No further evaluation (4)
Other (5) ________________________________________________

Q58 Somatic MMR testing and germline testing for MMR genes were both negative. Given this additional information, what do you perceive this patient’s chance of having Lynch syndrome to be?
- This patient absolutely has Lynch syndrome (1)
- It’s highly likely this patient has Lynch syndrome (2)
- It’s unlikely this patient has Lynch syndrome (3)
- This patient definitely does not have Lynch syndrome (4)

Q59 What screening recommendations would you give this patient?
- Population-level screening (1)
- Lynch syndrome screening (2)
- Other (3) ________________________________________________

Q60 What screening recommendations would you give this patient’s first-degree relatives?
- Population-level screening (1)
- Earlier colonoscopy based on family history (2)
- Lynch syndrome screening (3)
- Other (4) ________________________________________________

Start of Block: Conclusion

Q60 Would additional, more specific, national guidelines for ordering and/or the interpretation of MMR somatic tumor testing be beneficial to you?
- Yes (1)
- Maybe (2)
- No (3)
- Unsure (4)

Q61 Do you have any additional comments that were not addressed by this survey?

Danielle Rae Williams was born in Colorado, the daughter of Connie and Aaron Williams. After completing her work at Rock Canyon High School, Lone Tree, CO in 2012, she entered the University of Colorado in Boulder, Colorado. She received the degree of Bachelor of Arts with a major in molecular, cellular, and developmental biology from the University of Colorado in May 2016. For the next year, she worked as a genetic counseling assistant at the Huntsman Cancer Institute in Salt Lake City, Utah. In August of 2017, she entered The University of Texas MD Anderson Cancer Center UTHealth Graduate School of Biomedical Sciences.
